This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

THE
NEW AMERICAN CYCLOPÆDIA.

PARR, Samuel, LL.D., an English scholar, clergyman, and author, born at Harrow-on-the-Hill, Jan. 15, 1747, died March 6, 1825. He was the son of a surgeon and apothecary. He early manifested a taste for learning, and when, at the age of 15, he was removed from school and placed at his father's business, he devoted his leisure time to the study of Greek and Latin with such assiduity that in 1765 his father reluctantly consented to his entering the university of Cambridge. The death of his parent obliged him to accept in 1767 the first assistant mastership of Harrow school, where he remained 5 years. Having been rejected by the governors as a candidate for the vacant head mastership in 1771, he taught a school on his own account at Stanmore, and in 1777 became master of the school at Colchester, where he was ordained priest, receiving the curacies of Hythe and Trinity church. In the following year he was appointed master of Norwich school. Two sermons "On the Truth and Usefulness of Christianity" and "On the Education of the Poor" (1780) appeared during his residence here, and the latter served to prepare the way for his much admired "Discourse on Education, and on the Plans pursued in Charity Schools" (1785). In the mean time the university of Cambridge had granted him the degree of LL.D. (1781), and Bishop Lowth had appointed him a prebendary of St. Paul's. In 1786 he removed to Hatton in Warwickshire, where he held a perpetual curacy, and here he passed the remainder of his life, engaged in literary pursuits, the care of his parish, and the instruction of children. His personal unpopularity with the members of his own profession and the dispensers of government patronage prevented his rising to those dignities in the church to which his learning entitled him. He was vain, arrogant, and quarrelsome, a violent whig partisan, and both unjust and inconsistent in many of his political opinions. He advocated the repeal of measures against the Roman Catholics and Unitarians, but could not tolerate Methodists. In his controversial writings he was frequently unfair and untruthful, but he possessed great natural benevolence, and is said to have surpassed in conversational powers all his contemporaries except Dr. Johnson. In 1787 he published an edition of *Bellendenus de Statu*, with a preface in which he eulogized Burke, Fox, and Lord North, but attacked other contemporary statesmen with great virulence. It is esteemed one of the most successful modern imitations of Ciceronian Latin. His preface to an edition of "Tracts by Warburton and a Warburtonian, not admitted into the Collection of their respective Works" (1789) is remarkable for its polished style; but the work was undertaken in order to annoy Bishop Hurd, the editor of Warburton. His other writings comprise a controversy with Dr. White, whom he accused of plagiarism in his "Bampton Lectures" (1790), papers connected with the Birmingham riots of 1791, a controversy with Dr. Charles Combe in 1795, and one with Godwin and others occasioned by Parr's Spital sermon in 1800, and "Characters of the late Charles James Fox" (1809), consisting partly of original and partly of selected matter. He left a considerable number of historical, critical, and metaphysical papers in manuscript. An edition of his works, with a memoir of his life and writings and selections from his correspondence, was published by John Johnstone, D.D. (8 vols., London, 1828).

PARR, Thomas, commonly known as Old Parr, an Englishman celebrated on account of his great age, born in Winnington, Shropshire, in 1483, died in London, Nov. 15, 1635. He was the son of poor parents, and after his father's decease continued his occupation of husbandry. He was first married at the age of 80, and begot two children; and after the death of his wife, he married again when about 120 years old. According to a current story, he was engaged in a love intrigue when about 105 years old, and was compelled to do penance for the crime by standing in a sheet in Alderbury church. When a little over 152 years old, he was taken to London by Thomas, earl of Arundel; but dying soon after, he was buried in Westminster abbey. Almost all that is authentically known in regard to him is contained in a pamphlet published in 1635 by John Taylor, under the title of "The Olde, Olde, Very Olde Man; or, the Age and Long

Life of Thomas Parr, the Sonne of John Parr, of Winnington, in the Parish of Alderbury, in the County of Salopp, who was born in the reign of King Edward the IVth, and is now living in the Strand, being aged 152 years and odd monthes. His manner of life and conversation in so long a pilgrimage; his marriages, and his bringing up to London about the end of September last, 1635."

PARRHASIUS, a Greek painter, born in Ephesus, flourished about 400 B. C. He was the son and pupil of Evenor, and, although belonging to the Ionian school of art, passed the greater part of his life in Athens, of which city he was made a citizen. Quintilian calls him the legislator of his art, from the fact that he established certain canons of proportion for the human figure which were adopted by succeeding artists; and Pliny says: "He first gave to painting true proportion, the minute details of the countenance, the elegance of the hair, the beauty of the face, and by the confession of the artists themselves obtained the palm in his drawing of the extremities." He was arrogant and insolent in manner, and in epigrams inscribed on his own productions called himself 'Αβροδίαιτος, the elegant, claiming a divine descent, and announcing that in his works the art of painting had reached its highest excellence. His most celebrated work, according to Pliny, was an allegorical representation of the Athenian people, in which every quality, good or bad, ascribed to the Athenians, found its expression. Among other famous works by him were a Theseus, of which Euphranor remarked that it had fed upon roses, and his own Theseus upon beef; "Ulysses feigning Insanity;" a Meleager, Hercules, &c. He also painted pictures of a gross and licentious character, two of which, the "Archigallus" and the "Meleager and Atalanta," were so highly prized by the emperor Tiberius that he caused them to be hung in his own chamber. Two well known contests in which he engaged with contemporary painters are recorded. In the first, when conquered by Timanthes, the subject being the combat of Ulysses and Ajax for the arms of Achilles, he observed that he cared little for his own defeat, but felt pity for Ajax in being a second time overcome by an unworthy rival. In the second contest, which was with the painter Zeuxis, the latter executed a bunch of grapes so naturally that the birds came and pecked at the fruit. He thereupon requested Parrhasius to draw aside a curtain which apparently concealed his own picture; but as the curtain proved to be the picture itself, the victory was conceded by Zeuxis to his rival, who by deceiving men had gone further than himself in the art of imitation. The story told by Seneca, that Parrhasius, when painting a "Prometheus Chained," put an Olynthian captive to the torture, in order to obtain from him the proper expression of bodily suffering, has been proved to be utterly unfounded.

PARROT, the general name of the *psittacidæ*, a family of scansorial birds, remarkable for the elegance of their form, the brilliancy of their plumage, and their docility and power of imitating the human voice. They have a large strong bill, much arched, with acute tip, and the lower mandible notched at the end; the upper mandible is movably articulated to the frontal bones, enabling them to seize larger objects than other birds of their size; the tongue is thick and fleshy, the wings and tail generally long, tarsi short and robust, and the strong toes directed 2 before and 2 behind, the former united at the base by a narrow membrane. These are the typical climbers, but are slow and generally awkward on the ground; they use both bill and claws in climbing, and while feeding use one foot to hold their food; though rather sedentary, most of them are good fliers; the neck is short, and has usually 12 vertebræ; the sternum is long and narrow, with generally an oval aperture on its inferior margin on each side; the structure of the tongue and the complicated lower larynx enable them to articulate with great distinctness. They are confined to the warm parts of America, Asia, Africa, and Australia, and generally to the southern hemisphere; their food consists of soft pulpy fruits, especially such as have hard kernels or seeds; they are usually seen in large flocks, active in the morning and evening, noisy and quarrelsome, destructive to vegetation in their wild state, and very mischievous in captivity; they are monogamous, and build their nests generally in hollow trees. This is a very extensive family, numbering about 300 species, and divided by Gray into the sub-families of *pezoporinæ*, *arainæ*, *lorinæ*, *cacatuinæ*, and *psittacinæ;* the first 4 are described respectively under the titles Paroquet, Macaw, Lory, and Cockatoo, leaving for this article only the *psittacinæ*, and the genus *conurus* of the macaws. Some of the parrots present raptorial characters in the form of the bill, and especially in its soft skin or cere. Bonaparte makes of them a distinct order, placing them at the head of his system, separated from the typical *scansores* by the rapacious birds; for the connecting links between the families see Owl, and Owl Parrot.—The only well ascertained species within the United States is the Carolina parrot (*conurus Carolinensis*, Kuhl); in this the length is about 14 inches, and the alar extent 22; the bill is short, bulging, and very strong; the head is large, the neck robust, and the body and tail elongated, the latter wedge-shaped; the bill is white and the iris hazel; general color green with bluish reflections, lightest below; fore part of head and cheeks bright red, extending over and behind the eye, the rest of the head and neck gamboge yellow; edge of wing yellow tinged with red; wings and their coverts varied with bluish green, greenish yellow, and brownish red; 2 middle tail feathers deep green, the others with the inner webs brownish red; thighs yellow.

This species has been seen as far north as Lake Ontario, though now it is chiefly confined to the southern and south-western states, and as far as the Missouri to the west. They are very fond of the seeds of the cockle bur, and eat almost any kind of fruit and grain, from their immense flocks committing great havoc in the garden, field, and orchard, destroying in search of seeds far more than they consume; they are killed in large numbers by the enraged farmers, who consider their flesh a delicacy. The flight is rapid and direct, with great inclinations of the body and incessant noisy cries; they generally alight close together on the trees bearing the desired fruit; they are savage when wounded, but are easily tamed by immersion in water; they are destructive in captivity, and incapable of articulating words. They are fond of sand and saline earths. Many females deposit their eggs in the same hollow of a tree, each one laying 2 or 3. Several other parrots are found in Mexico and Central America.—To the subfamily of *psittacinæ* belong the parrots best known in the domesticated condition, especially the gray and green parrots so common as pets; in this group the head is without crest, the margins of the bill are dentated or festooned, the wings pointed, and the tail short and square. In the old genus *psittacus* (Linn.) the bill is large, rather compressed, with biangular culmen much arched to the tip, near which the lateral margin is deeply notched, the under mandible much sinuated and the anterior edge sharp; wings generally reaching to the end of the tail, with 2d and 3d quills equal and longest. There are more than 40 species found in the humid forests of Africa and South America; collecting at night in immense flocks, they leave their roosting places early in search of food, which consists chiefly of pulpy fruits and seeds, after which they bathe and retire to thick-leaved trees during the heat of the day, going in search of food again at night; they migrate in large flocks to warmer regions on the approach of the rainy season, rising to a great height and uttering the most discordant screams; the young are fed with the disgorged half masticated food of the parents. The gray parrot (*P. erythacus*, Linn.) is the most remarkable for its docility and power of articulating words, and is the one about which so many wonderful tales are extant; it is about 12 inches long, of an ash-gray color, with a bright scarlet tail, yellowish white irides, and grayish feet and toes. It is a native of W. Africa, whence it has been imported from a very early period; its habits are not very well known in the wild state, but in captivity it feeds on bread and milk, nuts, and even meat, holding its food with one foot, and reducing it to small pieces by the bill and cutters on the palate; it may reach the age of 70 and even 90 years. They breed readily in captivity. Anecdotes of these parrots might fill a large volume; it will be sufficient to say here that many of the recorded apposite speeches made by them are the result of the fortunate repetition of previously acquired sentences, and are not new words dictated by intelligence or any consciousness of their applicability. Large sums have been paid for well taught specimens, and a cardinal is said to have given 100 golden crowns for one which could repeat the Apostles' Creed; another is said to have served acceptably as chaplain of a vessel, reciting the prayers to the sailors. In the genus *chrysotis* (Swains.), of tropical South America, the bill is smaller but strongly dentated; the wings reach to the middle of the tail, which is broad and rounded. The green parrot (*C. Amazonicus*, Gmel.) is very often taken to the United States and Europe on account of its great colloquial powers; it is 12 inches long, the bill orange yellow, as well as the cheeks and chin; the general color is shining green, with a bluish purple band over the forehead, and the feathers of the hind neck edged with black; it inhabits the country watered by the river Amazon, where it often does great mischief to the plantations. The festive parrot (*C. festivus*, Linn.), a native of the same forests, is 15 or 16 inches long, of a general green color, with a narrow red frontal band and eye streak, blue above and behind the eyes, lower back and rump vermilion, and the greater quills with blue outer webs and the inner greenish black; it is docile, easily tamed, and learns readily to pronounce words and sentences. The last two species are those most commonly brought from South America; there are several others described. In the genus *psittacula* (Briss.) the size is generally small; the bill is rather large with the lateral margins festooned; the pointed wings extend to the end of the tail, which is short and even; there are about 60 species described, in South America, Africa, and Asia and its archipelago; they are rapid fliers and expert climbers, often hanging head downward in their search for fruits; while feeding they utter a shrill chirp, like that of a large grasshopper; when sleeping they generally suspend themselves by one or both feet, head downward. Here belong the beautiful little "love birds," the genus *agapornis* of Selby. Swindern's love bird (*P. Swinderniana*, Kuhl) is a native of S. Africa; it is about 6 inches long, with a black strong bill whose upper mandible is notched; the head and nape are bright green, bounded by a black nuchal collar; neck and breast yellowish green, mantle and wings green, lower back and upper tail coverts azure blue; the short and nearly even tail has a median bar of vermilion edged with black and the tip green. These parrots are remarkable for their attachment to each other. Other genera are *tanygnathus* (Wagl.), of the Moluccas and New Guinea, having a very large and swollen bill without dentations, a very long, broad, and wedge-shaped tail, short tarsi, and long slender toes; and *nasiterna* (Wagl.), which is a very small New Guinea genus, having a short elevated bill, and the apex of each feather of the short rounded tail prolonged into an acute point; the *N. pygmæa* (Wagl.) is the smallest of the parrot family.

PARROT, Johann Jakob Friedrich Wilhelm, a German natural philosopher, born in Carlsruhe, Oct. 14, 1792, died Jan. 15, 1841. In 1811 and 1812 he travelled in company with Engelhardt over southern Russia and the Caucasus, and on his return published an account of his travels under the title of "Travels in the Crimea and Caucasus" (2 vols., Berlin, 1815–'18). In 1821 he was appointed professor of physiology, pathology, and semeiology in the university of Dorpat, travelled in 1824 in the Pyrénées, and in 1829 was the first to make a successful ascent of Mount Ararat. He wrote "Journey to Ararat" (2 vols., Berlin, 1834; English translation by Cooley, London and New York, 1845); a treatise on "Gasometry" (Dorpat, 1814); and "Views in regard to Universal Pathology" (Riga, 1821).

PARROT FISH, the common name of the numerous cyclolabroid fishes of the genus *scarus* (Forsk.); the name is derived from the beak-like form of their jaws; they also present the same brilliancy and variety of colors as do the parrots among birds. The form is oblong and stout, with the lateral line branching and interrupted under the end of the dorsal fin. The jaws are prominent, convex, each divided into halves by a median suture; the teeth are incorporated with the bone, arranged in an imbricated manner in crowded quincunxes, the oldest forming the cutting border, and succeeded by the lower ranks as the former are worn away; their surface is generally smooth and polished; the pharyngeal teeth consist of trenchant transverse vertical plates, two above and one below, presenting when worn narrow ellipses of dentine surrounded by enamel; the lips are simple and fleshy, in some species leaving the teeth exposed. The body is covered with large scales, as far as the gill covers and cheeks, there being from 21 to 25 in a longitudinal line and 8 in a vertical one at the region of the pectorals; those at the base of the caudal fin are large and embrace a considerable portion of its rays; there is a single conical dorsal, with 9 spiny and 10 articulated rays; the anal has 2 spiny and 8 articulated rays. The muzzle is obtuse, and the profile sometimes rather high; there are no stomachal nor pancreatic cæca. There are about 100 species described, living principally on the coral reefs of the West and East Indian archipelagos, about one quarter dwelling around the Molucca and Sunda islands. The best known is the parrot fish of the Mediterranean (*S. Cretensis*, Rond.), of a red or blue color according to season, highly esteemed by the ancients; it is about 15 inches long, of a general purplish color, roseous below, and violet brown on the back; the pectorals orange, ventrals with transverse lines of violet, and dorsal violet gray with golden spots and bands. There is more said of this fish in the ancient writers than of any other; in Pliny's time it was ranked as the first of fishes, and large sums were expended to stock the Italian waters with it from the sea between Crete and Asia Minor. By the ancients it was believed to have a voice, to sleep at night (alone of fishes), to be very ardent in the pursuit of the female, to release its companions and other fishes from nets, and to have the power of ruminating; the last belief naturally arose from the backward and forward movements of the jaws rendered possible by the mode of articulation, and necessary for the complete mastication of the sea weeds upon which it principally feeds. Its flesh is tender, sweet, and easy of digestion, and the intestines and their contents were highly relished; the modern Greeks call it *scaro*, and consider it a fish of exquisite flavor, eating it with a sauce made of its liver and intestines, as the moderns eat plover and woodcock; its liver entered into the composition of the famous dish called "the shield of Minerva," with the brains of the peacock and pheasant, flamingoes' tongues, and the milt of the muræna eel. The red parrot fish of the West Indies (*S. Abilgaardii*, Val.), about 16 inches long, is a handsome species. The great parrot fish (*S. guacamaia*, Val.), from the same locality, attains a length of 2¼ or 3 feet, and a weight of 80 lbs.; the colors are red, blue, and green. Many other beautiful species are described from North America in Dr. Storer's "Synopsis," and the whole genus is treated at length in vol. xiv. of the *Histoire naturelle des poissons* by Cuvier and Valenciennes.

PARRY, Sir William Edward, an English navigator, born in Bath, Dec. 10, 1790, died at Ems, Germany, July 8, 1855. He was the son of a physician, and was intended for his father's profession; but after he had received a good education at the grammar school of his native place, a relative induced him to enter the navy. In June, 1803, he was appointed a first class volunteer on board the Ville de Paris, 110, the flag ship of Admiral Cornwallis, and remained in this vessel until 1806, when he was rated as midshipman on the Tribune frigate. Having been transferred to the Vanguard, 74, of the Baltic fleet, he was several times in action with the Danes, and in one engagement was intrusted with the command of one of his ship's boats. In 1810 he obtained his commission as lieutenant, and sailed in the Alexandria frigate to the polar seas about the North cape, where he corrected the admiralty charts of those waters. After the outbreak of war between Great Britain and the United States, he was sent to Halifax (1813) to join the La Hogue, 74, with whose boats in the spring of 1814 he ascended the Connecticut river about 20 m., and destroyed 27 privateers and other vessels with the loss of only 2 men. He remained on the North American station until 1817, when, hearing that two expeditions, the one under Buchan and Franklin and the other under Capt. Ross, were about to be sent out to the north polar regions, he solicited employment, and was placed in command of the Alexander under the orders of Ross in the Isabella. They left England in April, 1818, and proceeded to Lancaster sound, which they navigated for about 60 m., when Ross, imagining that he saw the way closed before them by a range of mountains, gave orders to return. Parry freely expressed his conviction that the range of mountains was an optical illusion; and as the public generally coincided in this opinion, it was determined in the spring of 1819 to equip a fresh expedition under his command. With the Hecla, 375 tons, and the Griper gun brig, 180 tons, Lieut. Liddon, he reached Lancaster sound July 30, and sailed through it. He explored and named Barrow straits, Prince Regent inlet, and Wellington channel, and, entering the water which has since been called Parry sound, reached on Sept. 4 long. 110° W., thereby earning a reward of £5,000 offered by parliament to the first ship's company which should attain that meridian. He wintered at Melville island, and his expedients to preserve the health and spirits of his crews during the long arctic night were scarcely less deserving of mention than his achievements as a discoverer. Exercise was rigorously enforced, all possible precautions were taken against scurvy, and a newspaper and theatre were provided as amusements. On Aug. 2, 1820, after being frozen in for 10 months, the ships were released; but the state of the ice was such as to preclude the hope of further progress westward, and Parry accordingly returned to England, where he was welcomed with the utmost enthusiasm. He was promoted to the rank of commander, presented with the freedom of Bath and Norwich, and elected a member of the royal society, and the narrative of his adventures was published by order of the admiralty. The results of his voyage, beside the establishment of the navigability of Lancaster sound and the existence of a polar sea to the north of America, were extremely important to the science of magnetism, no observations having ever before been made so near the magnetic pole. The great problem however of the north-west passage was still unsolved, and in May, 1821, Parry sailed again with the Fury, accompanied by Capt. Lyon in the Hecla. He passed through Hudson's strait and Fox's channel, discovered and named the Duke of York's bay on the N. shore of Southampton island, and passing through Frozen strait reached Repulse bay. After a season of fruitless exploration along these waters lying immediately N. of Hudson's bay, his ships were frozen in at Winter island, Oct. 8, and were not released again until July 2. He now sailed up Fox channel to the mouth of the strait separating Melville peninsula from Cockburn island, and named it Fury and Hecla strait. As it was frozen across, he made a journey on foot to the narrowest part of the strait, whence he could see in the W. an open expanse of water which he thought was the polar sea, but which is now known as the gulf of Boothia, at the S. extremity of Prince Regent inlet. On Aug. 26 they were again imprisoned by the ice, but they performed during the winter several land journeys, sufficient to convince them that any attempt to reach the polar sea through Hudson's strait was hopeless. The appearance of scurvy among his men induced him in the spring to return home, and on Oct. 10, 1823, he arrived at Brassa sound, Shetland. During his absence he had been promoted to the rank of post-captain (Nov. 8, 1821); and in Dec. 1823, he was appointed acting hydrographer to the admiralty. His "Journal of a Second Voyage for the Discovery of a North-West Passage" was published by the admiralty in 1824. The results of these voyages, however imperfect, were sufficient to encourage further search, and the Hecla and Fury were consequently refitted as speedily as possible. In May, 1824, Capt. Parry sailed again in the Hecla, with Capt. Hoppner in the Fury under his orders. His plan was to pass through Prince Regent inlet, but winter overtook him almost at the entrance of that channel; and soon after the ice broke up, July 20, 1825, his vessels were caught in the drift and carried down the inlet. On Aug. 21 the Fury was driven ashore, and so badly damaged that she had to be abandoned. Her crew and stores were transferred to the Hecla, and, deeming it impossible to continue the voyage under such circumstances, Capt. Parry returned to England, having accomplished little or nothing. His "Journal of a Third Voyage for the Discovery of a North-West Passage" appeared in 1826. He now turned his attention to a plan originally proposed by Scoresby for reaching the pole in boats which could be fitted to sledges and floated or dragged as occasion might offer; and having improved somewhat upon the original design and obtained the sanction of the admiralty, he set sail in the Hecla, March 27, 1827, for Spitzbergen. Here the vessel was left in harbor with a part of the crew, while the remainder, led by Capt. Parry and Lieut. James C. Ross, set out for the pole in two boats, June 22. These boats were framed of ash and hickory, covered with water-proof canvas, over which were successive planks of fir and oak, with a sheet of stout felt interposed. They were flat-bottomed inside, and had runners so that they could be used as sledges. The adventurers sailed through an open sea for about 80 m., and then found, not as they had expected a solid plain of ice, but a surface half covered with water, on which walking and sailing were almost equally difficult. They entered this ice June 24, and after 5 nights of laborious travelling (for they travelled only by night to avoid snow blindness) had advanced only 10 miles. After reaching harder ice their progress became more rapid, but on July 19 a north wind sprang up which proved a more formidable obstacle than any they had yet experienced. It was found that the ice moved southward while they were travelling toward the north, and on the 24th they were 4 m. S. of the position occupied on the 22d. It was evidently impossible to proceed further, and they began to retrace their steps, having reached as far N. as lat. 82° 45', the nearest point to the pole that had been reached by any expedition, and travelled in a direct line 172 m. from the ship, to accomplish which distance they had been obliged to pass over 668 m. of surface. They reached the Hecla after an absence of 61 days, and at the end of September arrived in England, where Capt. Parry published his "Narrative of an Attempt to reach the North Pole in Boats fitted for the Purpose" (1827), and resumed his duties as hydrographer to the admiralty. On April 29, 1829, he was knighted by George IV., Sir John Franklin receiving the same honor at the same time. Both these distinguished navigators also received from the university of Oxford the degree of D.C.L. Parry now received the appointment of commissioner of the Australian agricultural company, the mismanagement and neglect of whose agents had reduced their settlements to the condition of "a moral wilderness." He took ship July 20, 1829, and passed 5 years at Port Stephens, about 90 m. from Sydney. Returning to England in 1835, he received from the company a service of plate "in testimony of the high sense entertained of the benefits conferred by him on the colony during his residence there;" was appointed assistant commissioner of poor law for the county of Norfolk, an office which he was obliged to resign on account of his health at the end of 18 months; was employed by the admiralty in 1837 to organize the packet service between Liverpool, Holyhead, and Dublin; and in April of the same year received the newly created office of comptroller of steam machinery for the royal navy. During his term of office the use of steam in the navy, which had already been tried to a considerable extent, became almost universal, and the introduction of the screw propeller was in great measure owing to his persevering advocacy. In 1841, at the request of Sir Robert Peel, he drew up a report on the state of the Caledonian canal, in which he recommended its adaptation for vessels of large draught, a measure which was accordingly adopted. He retired from active service in Dec. 1846, with the appointment of captain-superintendent of the royal Clarence yard and of the naval hospital at Haslar near Portsmouth, retaining this position until 1852, when he was compelled to vacate it on attaining the rank of rear admiral of the white. In the following year he was made lieutenant-governor of Greenwich hospital. In the summer of 1854 he was attacked by cholera, which entirely undermined his constitution, and induced him to go to Germany, where he died. Beside the narratives of his 4 voyages, he wrote a treatise on "Nautical Astronomy by Night;" "The Parental character of God;" and a "Lecture to Seamen." His life has been written by his son, the Rev. E. Parry (London, 1857).

PARSEES. See Guebres.

PARSLEY (*petroselinum sativum*, Hoffman), an exogenous hardy biennial plant of the natural order *apiaceæ*. This order is composed of herbs with stems either solid or fistulous and furrowed, leaves usually divided and sheathing at base, and numerous small flowers borne in umbels and surrounded by an involucre; in color either white, pink, yellow, or blue; the fruit (commonly considered as the seed) consisting of 2 carpels separable from a common axis to which they adhere by their face (commissure), each carpel traversed by elevated ridges, of which 5 are primary, and 4 alternating with them are secondary; between these ridges are sometimes lodged receptacles of oily matter called *vittæ*. The plants of this order are extremely rare in the hotter regions of the globe.—The common parsley is a native of Sardinia, and has been cultivated in gardens for 3 or more centuries. Its stem is angular, its leaves shining and tripinnate, the leaflets toothed; its flowers are borne in compound umbels furnished with general and partial involucres; the sepals abortive, the petals 5 and equal; the fruit ovate, contracted at the side, furnished with 5 narrow, equal ridges, the lateral ridge on the edge and each furrowed ridge with one vitta; the albumen plano-convex. The most usual form seen in gardens is what is called the double-leaved or curled-leaved, having a beautiful thick-leaved, curled, and crisp foliage, highly ornamental as well as of superior quality; this however is only a mere permanent variety of the plain-leaved or common form, which used to be solely raised for its leaves, and which is still cultivated. Another is known as the Hamburg, raised for the roots alone, which are cut up and employed in seasoning soups and stews, their superior size rendering them better than the roots of the other varieties. The leaves, as is well known, are the parts usually employed for the table, both for imparting flavor and as a garnish to meats. Parsley is sometimes sown among pasture grasses, to counteract by its presence the tendency to liver rot in sheep. In gardens it should be sown as early as possible in the spring, and a slight covering in winter is found advantageous to the young plants. The Hamburg should be thinned out frequently so that the plants may be allowed as much as 10 or 12 square inches of surface. In medicinal quality parsley is considered pleasant, stimulating, aromatic, and diuretic.

PARSNIP (*pastinaca sativa*, Linn.), a biennial, umbelliferous plant, growing wild in the chalky districts of England near the sea coast, and cultivated for the sake of its root, which has a sweet taste and nutritious qualities, and is used both as a table dish and for cattle. The common parsnip has an angular, furrowed stem, pinnated, smooth leaves, hairy beneath, the leaflets oblong, blunt, crenate-serrate, the terminal one 3-lobed; the flowers are yellow and borne in a compound umbel, usually without involucres; the calyx obsolete; the petals 5, lanceolate, involute, uniform, entire; the stamens 5, pistils 2; fruit thin, surrounded by a broad border, with oil receptacles (*vittæ*), one in each furrow. The parsnip when growing wild by straying from gardens is materially affected in its nature and habits, and its root becomes small, strong, acrid, and virose; but under cultivation in a suitable soil, the root grows to a large size and penetrates the ground to a great depth. The soil it prefers is mellow, deep, and rich, and not apt to dry. The best flavored roots are produced in a soil inclining to sand rather than to loam. The ground in the garden should be spaded deep, as the quality of the crop depends much upon the length of the roots. The usual mode of cultivation is to sow them in drills and thin out as needed; they should be at least 6 inches apart if large roots are required, and sowed as early as possible in the spring; some prefer sowing in the previous autumn. When manure is used, it should be rotten and free from lumps and straw, and no great amount is needed, as the crop is not exhaustive. The early frosts of autumn do not affect the tops and roots, but there is no advantage in wintering them in the ground as some do, and the first renewal of growth in the spring causes them to become tough and have a bitter flavor. The best treatment is to dig them up in the autumn, taking care not to cut the roots, and not to trim off the tops too closely. A cool and dry cellar is better than one in which if stored they might sprout and grow.—Some agricultural writers have recommended the parsnip as an excellent food for swine, and as useful for feeding and fattening all kinds of cattle. A variety called the *coquaine*, the roots of which sometimes run 4 feet deep, is raised in Jersey and Guernsey chiefly for feeding milch cows. According to Sir Humphry Davy ("Agricultural Chemistry"), in 1,000 parts there are 90 saccharine and 9 mucilaginous. In Scotland the roots are largely used for food by the peasantry; and when they are rasped raw and mixed with flour good bread is made of them. In Ireland a sort of beer is brewed from the roots; and wine is made in England by boiling them, adding a little sugar to the expressed juice, and fermenting by yeast, distillation affording a spirituous liquor. The best foreign varieties of the parsnip are the Guernsey, hollow-crowned, and round or turnip-rooted; and in the eastern New England states, the cup parsnip is decidedly preferred. The wild parsnip of American fields is a European exotic, and is regarded as a noxious weed.

PARSON (Lat. *persona ecclesiæ*), in English law, one having full possession of all the rights of a parochial church. (See PARISH.) He is a sole corporation, and possesses the rights of the church by perpetual succession. During his life he has a freehold estate in the glebe, and in the tithes, unless where they are appropriated (sometimes called impropriated) to the lord of the manor or other patron of the living. The word parson has lost somewhat of the importance attached to the name; and 100 years ago Blackstone spoke of it as "depreciated by familiar, clownish, and indiscriminate use," but as still "the most legal, most beneficial, and most honorable title that a parish priest can enjoy." In the United States the word is not understood as having any legal or official meaning, but is commonly used as designating a minister of the gospel; but it is not often applied to a priest of the Roman Catholic or of the Episcopal church, and it has lost so much of its original solemn and official meaning, that it is commonly used in a familiar rather than a reverential or even respectful sense.

PARSONS, THEOPHILUS, an American jurist, born in Byfield, Essex co., Mass., Feb. 24, 1750, died in Boston, Oct. 30, 1813. He was graduated at Harvard college in 1769, and in the succeeding year commenced the study of the law in Falmouth, now Portland, Me., where he was admitted to the bar in July, 1774. During this interval he contributed to his support by teaching a school. He commenced practice with unusually brilliant prospects; but the almost total destruction of Falmouth by a British fleet, in Oct. 1775, having interrupted his career in that place, he returned to Byfield, and for several years received the instruction and assistance of Judge Trowbridge, called by Chancellor Kent "the oracle of the common law in New England." In the library of this jurist, one of the best in America, he laid the foundation of a vast accumulation of legal learning; and the manuscript briefs on questions incidentally occurring to him, which he there prepared, were frequently employed by him with advantage during his subsequent career at the bar and on the bench. Establishing himself in Newburyport, he entered upon a lucrative practice, which gradually embraced all the New England states. At the same time he took a considerable interest in the politics of the day, his opinions being of that conservative stamp which subsequently characterized the federal party. In 1778 he formed one of the so called "Essex junto," a body of citizens of Essex county who opposed the adoption of the state constitution recently framed by the Massachusetts legislature; and a pamphlet, familiarly know as "The Essex Result," stating the principal objections to the proposed constitution and approved and adopted by the "junto," was probably wholly prepared by him. It was widely circulated throughout the state, and had an important influence in causing the rejection of the constitution. In 1779 he was a delegate to the convention which framed the state constitution finally adopted. As a member of the convention which assembled in Boston in Jan. 1788, to ratify the federal constitution, he took an active and influential part in favor of that instrument, and was the author of the "Proposition," offered by John Hancock and subsequently adopted, ratifying the constitution and recommending certain amendments, known in the histories of the times as the "conciliatory resolutions." He occasionally served in the legislature after this, but took no prominent part in public affairs, although to the close of his life he remained a consistent federalist. In 1800 he removed to Boston; and upon the retirement of Chief Justice Dana in 1806, he was appointed to succeed him upon the bench of the supreme judicial court, which position he held at the time of his death. As a lawyer and as a judge he was greatly respected. In the former capacity Justice Story declared that he "had no equal," and was "a head and shoulders taller than any other man in the whole state;" and his judicial opinions were so highly esteemed that a collection of them was published in New York under the title of "Commentaries on the Law of the United States, by Theophilus Parsons, late Chief Justice of Massachusetts." His decisions threw much light upon the laws of pleading, marine insurance, and real property, and he rendered a substantial service to the community by discountenancing delays and expediting the trial of causes. Apart from his professional duties, he was distinguished as a classical scholar, and as a mathematician of considerable ability; and in private life he was esteemed for many amiable qualities. An elaborate memoir of him has been published by his son, Theophilus Parsons (12mo., Boston, 1859).—Theophilus, an American author and jurist, son of the preceding, born in Boston, Mass., May 17, 1797. He was graduated at Harvard college in 1815, studied law with Judge William Prescott, and after a brief visit to Europe entered upon the practice of his profession, first in Taunton, and afterward in Boston. For several years after his admission to the bar he was a constant contributor to the "North American Review," and wrote occasionally for Mr. Walsh's "American Review" in Philadelphia. He was also for some time connected with the "Free Press" and "New England Galaxy" newspapers, and founded and edited the "United States Literary Gazette." He was an early convert to the doctrines of the New Jerusalem church, and has written much in exposition and defence of them in its periodical publications. Two volumes of "Essays" have appeared from his pen, and other smaller works, written for the same objects. In 1847 he was appointed Dane professor of law in the Harvard law school, and has since resided at Cambridge, in the discharge of the duties of his professorship, occupying his leisure in the preparation of legal treatises. He has published the "Law of Contracts" (2 vols., 1853); "Elements of Mercantile Law" (1856); an elementary work called "Laws of Business for Business Men" (1857); and an elaborate and comprehensive treatise on maritime law, including the law of shipping, the law of marine insurance, and the law and practice of admiralty (2 vols., 1859).

PARSONS, Thomas William, an American poet, born in Boston, Aug. 18, 1819. He was educated in the Latin school of Boston, and in 1836–'7 visited Italy, where he imbibed a fondness for Italian literature, one of the earliest fruits of which was a translation of the first 10 cantos of the *Inferno* of Dante, published in Boston in 1843. In the interval he adopted the profession of a dentist, which he has since practised, although devoting his leisure to literary avocations. In 1854 appeared a volume of poems from him, containing "Ghetto di Roma" and other pictures of life in Italy, which he revisited in 1847, and also many pieces suggested by American subjects. He has completed his translation of the *Inferno*, but it has not yet been published.

PARTHENOGENESIS (Gr. παρθενος, virgin, and γενεσις, birth), a name given to the phenomenon in the organic world, believed by many to occur, though still questioned by others, of a production of successive generations of procreating individuals, originating from a single fertilized ovum, but without any renewal, through such series, of fertilization. Ordinarily careful observations seem, at first, to result in the rule that, certainly in the animal realm, and probably in the vegetable, offspring can only arise by means of a union of sexual elements, though this union may be either obvious or concealed. Yet there were those among the earlier writers who held to be possible what they called a *lucina sine concubitu*. M. Bonnet, about the middle of the 18th century, first gave a scientific standing to this opinion, by discovering that the *aphis* (plant louse) may produce a numerous offspring, and these be followed by several generations, without the intervention in any known or conceivable way of the masculine fertilizing principle. M. de Quatrefages proposed to name this result *agamogenesis*, or production without union. The name at the head of this article was applied to certain cases of this kind by Professor Owen. Of Siebold's work on this subject a translation appeared in London in 1857. Strictly, the name parthenogenesis is hardly appropriate, since either the producers in these cases are not perfect ordinary females, or the production is not that of perfect ordinary offspring; or both these circumstances may be true. Siebold investigated this uni-sexual, or at least unusual generation, in certain sac-bearing *lepidoptera*, in the silkworm moth, and in the honey bee. In the first, females only result; in the second, both sexes. Along with Dzierzon, he obtained in relation to the honey bee the most complete set of observations. The queen bee, impregnated once for all for her 5 or 6 years of life, deposits thereafter, at proper periods, the germs of successive swarms or colonies; and the microscope reveals the fact that the eggs destined to become workers (imperfect females) and queens (perfect females) are fertilized, as ordinarily, by contact or penetration of spermatozoids, while those to become drones (males) undergo no such influence; so that the production of these last is agamogenetic. In further proof, if the queen have her wings crippled from the first, so that she takes no flight, she produces only males, thus ruining the hive; and a like result may follow the pinching or freezing of one side of her body, and also, because the spermatozoids have become exhausted, in her old age. So, rarely, the workers may without fertilization produce eggs, but those of males only. But any of these males, though all directly agamic or fatherless, can become efficient in a return to the ordinary or bi-sexual mode of reproduction.—Bonnet's experiments with the aphis yield, as intimated above, more curious results. He carefully isolated a newly hatched aphis by conveying it upon a twig beneath a glass shade dipping into water. Of fourscore offspring produced alive by this insect, one was isolated in like manner, and with similar result; and this was repeated as long as the observations continued, or for 9 successive broods. As the young aphides are ready for propagation in about 2 weeks, it follows that in the course of a summer a single parent may have a progeny of millions, and all without renewed intervention of the male element. Kyber found that when warmth and food were abundantly supplied, this agamic production would go on for 2 or 3 years; but these broods, winged or wingless, consist almost wholly of imperfect females, seldom any males. The true females, always wingless, produce only after sexual union, and then eggs, not living offspring. And ordinarily, as the cold of autumn increases and the supply of food fails, the agamic young give place to true males and females; the latter laying eggs which, the next spring, hatch out again viviparous or imperfect females. Thus there is a cycle of changes; a large but varying number of links of non-paternal, being interposed between any two of paternal generation. The imperfect females have, in place of ovaries, certain tubular organs, the germs lying in which develop into living insects. Thus the case is only apparently, not really, anomalous; the real individual of the aphides is the perfect male or female only, and union of these must occur for the perpetuation of the race; but under favoring conditions, by a sort of exuberance of vital activity, an intercurrent production by gemmation or budding sets in, terminating finally in a return to the normal individual. According to this view, the drone bees are another instance of production by budding; and still others are said to be found in the *daphnia* (water fleas), and in some species of butterfly.—Among examples believed to be found in the vegetable world, the most marked is that of the *cœlebogyne ilicifolia* (literally, "holly-leaved spinster"), sent from Moreton Bay, Australia, to the royal gardens at Kew. This tree is diœcious, and the single specimen found is pistillate; yet in its new locality it has flowered and borne fruit regularly; and though it is claimed that, with perhaps a single exception, no pollen has been found in or upon any of its flowers, yet the seed seems to be perfected, and the numerous plants already obtained from it do not appear to be hybrid. Braun found in one instance a pollen grain and tube on the stigma of the *cœlebogyne*; and he considers the seed of the plant perfect, while Klotzsch finds in it no embryo, but only a bud. It is doubtful whether any of the young plants of this species have as yet matured seed which could be again tested; and possibly the question of agamic production in plants must still be regarded as open. Regel found that after strongly cutting-in female plants of *spinacia* and *mercurialis*, male flowers were constantly developed, but which, without great care, would have been unnoticed; and reviewing these and other supposed cases, he concludes that "parthenogenesis certainly does not occur in plants with evident sexual organs." But Prof. Asa Gray, in apparent consistency with all the known facts, infers that parthenogenesis does occur in plants, and therefore probably not in 2 or 3 special cases nor in diœcious plants only; and that "sexual fecundation may be strictly necessary to the perpetuation of the species, without being strictly indispensable for every generation." ("American Journal of Science and Arts," 2d series, vol. xvii. p. 440.)

PARTHENON. See ATHENS, vol. ii. p. 291.

PARTHIA, in ancient geography, a district of western Asia, the boundaries of which varied at different times. Originally it was a small and mountainous country S. E. of the Caspian sea, and bounded by Persis, Susiana, Hyrcania, Aria, Carmania, and Media, and therefore including nearly all of the modern Kohistan, the northern portion of Khorassan, and a part of the Great Salt desert. It was divided into the districts of Comisene, Parthyene, Choarene, Apavarctene, and Tabiene, of which the two last were in the southern part. There were no cities of great importance. The largest was Hecatompolis, which during the reign of the Arsacidæ was the residence of the royal family. The chief mountains were the Labus or Labutas, probably part of the range now called the Elboorz mountains; the Parachoathras, now called Elwend; and the Masdoranus. The rivers were few in number, and scarcely more than mountain streams, almost dry during the hot season, but violent floods when the snow melted.—The Parthians, according to their own tradition, were of Scythian descent, their name signifying in that language "banished" or "exiles." This was the opinion of the ancients, although many modern writers suppose they were directly connected with the Iranian tribes. In their treatment of their princes and nobles they carried the usual obsequiousness of the oriental forms to excess. They were under the government of a double council, made up of the Magians and the nobles or relations of the king. In war they fought on horseback, the principal weapon being the bow; and the peculiar manner in which they fought, discharging their arrows while retreating, was often referred to by the Roman poets. Polygamy was very common.—The Parthians early became subject to the Persians. In the division of the empire by Darius Hystaspis into 20 satrapies, they, along with the Chorasmians, Sogdians, and Arians, formed the 16th. They constituted a part of the army of Xerxes in the expedition against Greece, and served under the last Darius. Parthia and Hyrcania formed under Alexander one satrapy; and after the death of that conqueror, the inhabitants of the former country joined the cause of Eumenes. Afterward they were governed successively by Antigonus and the Seleucidæ until 250 B. C., when under the leadership of Arsaces they became independent. The new kingdom constantly grew in power, gradually encroaching on the Bactrian possessions on the east, and on those of the Seleucidæ on the west, until the Parthian empire extended from the Euphrates to the Indus, and from the Oxus to the Persian gulf. The conquests of the Romans in Asia finally, about 60 B. C., brought that military nation in conflict with the Parthians. In 53 Crassus invaded their territory during the reign of Orodes, but was completely defeated, he himself being slain and his army cut to pieces. Elated by their victory, the next year they invaded Syria, but were driven back by Cassius, the proconsul of the province. Siding with Pompey in the civil war, and subsequently with Brutus and Cassius, they were defeated by Ventidius, the lieutenant of Antony, in 39, and by the same general again in 38, on the anniversary of the day of the defeat of Crassus, Pacorus, the son of Orodes, being slain in the battle. The war was continued after Phraates IV. ascended the throne, Antony marching into Media in 36, but being forced to depart after suffering severe loss. A treaty was made between the reigning monarch and Augustus, the former being threatened at the same time by the Romans and the disaffection of a large number of his own subjects. In this treaty Phraates restored to Rome the standards which had been taken on the defeat of Crassus. After the death of this monarch, Parthia became for many years the scene of civil wars between various pretenders to the throne. There were frequent conflicts with the Romans, especially in regard to the kingdom of Armenia, and during the reign of Trajan that emperor marched into Asia, and made Armenia and Mesopotamia Roman provinces. This territory was restored by his successor, but war again broke out during the reign of Marcus Aurelius and Aurelius Verus; and the conquests made by Cassius, the general of the latter, which were continued by Septimius Severus and Caracalla, effectually weakened the strength of the Parthian empire. At length, seeing the prostrated condition of the kingdom, Artaxerxes, representing himself as belonging to the ancient dynasty of the Persians, induced that people to throw off the yoke. Artabanus IV., the last emperor of the Arsacidæ, was defeated and slain in A. D. 226, and the new Persian empire, under the rule of the dynasty of the Sassanidæ, took the place of the Parthian.

PARTICIPLE (Lat. *participium*, a partaking), a part of speech which partakes of the properties of both an adjective and a verb, and may be considered as an adjective with the idea of time added or as a verb without the idea of affirmation. In English there are two participles, the present and the past. The former ends in *ing*, but originally in *and*, which termination is seen in the participles of the cognate languages, as *ant* in Sanscrit, *ont* in Greek (as in the genitive *βουλευ-οντ-ος*), *ant* and *ent* in Latin (as in *am-ant-is* and *reg-ent-is*), and *end* in German. The past participle is formed usually by adding *en* or *ed* or *d* to the root of the verb; but the final *d* in some cases becomes *t*. In the power and expressiveness gained by the use of the participles, the modern languages are inferior to the ancient.

PARTITION, in law, the severance of common or undivided interests. It is particularly applied to interests in realty. At common law lands held by two or more persons were held by them either in joint tenancy, in common, or in coparcenery. The first two of these estates were created by the act of the parties. The last was created by operation of the law, when in casting a descent it devolved a single estate upon two or more heirs; as, for example, when an estate in fee of one who left no male succession passed to his daughters or other female representatives. These persons were called coparceners. Theirs was the only joint estate of which the common law would compel a dissolution at the request of a single party. Joint tenants and tenants in common became so, said the law, by their own mutual agreement and act, and the tenancy could be justly severed only by their mutual consent. But coparceners are rendered so by operation of law, and lest any one of them be prejudiced by the perverseness of his fellows, the law will lend its aid, if he ask it, and help him, by partition, to the enjoyment of his separate interest. In the reigns of Henry VIII. and of William IV. special statutes extended this common law benefit, which hitherto coparceners alone had enjoyed, to joint tenants and tenants in common; so that partition then became incident to all estates held in common.—In the United States the technical joint tenancy is quite abolished; joint ownerships being, if not under express statutes, yet in effect, only tenancies in common. So also the technical distinctions between estates in common and in coparcenery have lost nearly all their force. Much therefore of "the cunning learning of partition," as it exists in the English law, is inapplicable here. Yet as among us real property generally passes, on the death of an *ancestor*, to more persons than one, partition still retains an importance in respect to the tenancies in common of heirs and devisees. In some parts of the country, the operation of this remedy is extended by statutes beyond the limits fixed for it by the common law or the statutes of Henry VIII.—Partition, in England, was made either by mutual consent or upon compulsion. In the latter case, the relief was sought either by a writ of partition, sued out by one party, at common law, or by his petition to the court of chancery. If the courts of law ever had exclusive jurisdiction of partition, as it is sometimes asserted, it must have been at a very remote period. For, as early as the reign of Elizabeth, it is certain that chancery took cognizance of the matter, and lately it has enjoyed almost exclusive jurisdiction over it; for the courts of law are rarely invoked to make partition, though their jurisdiction is concurrent with that of chancery. There is good reason, however, for the preference of the chancery courts. The procedure at law in a cause of partition is far less effective than that in equity. The courts of law are limited to a mere allotment according to the proportional shares of the parties in interest; and this often causes a purely mechanical, and so prejudicial, division of an estate. But chancery, not restricted to the exact balancing of equivalent shares, but capable of all equitable adjustments of the matter, may distribute among the claimants the separate, though unequal, parcels of the estate, assigning to the several parties the portions which will best suit their respective condition, equalizing such a partition by decreeing pecuniary compensation to be made, or in other cases ordering equitable payments by some for improvements made in the common property by others. This jurisdiction is exercised with peculiar fitness in all cases where purely equitable rights, conflicting claims of parties, or modes of enjoyment are to be adjusted. Courts of equity will interpose only when the title of their petitioner is clear. If it be contested, he must try it at law. Wherever, in our states, distinct equity courts exist, they probably have *concurrent* jurisdiction with courts of law in respect to partitions, and, in general, such a jurisdiction as has just been described. But in almost all the states the cognizance of partitions is regulated by very minute statute provisions, and to these in each state reference must be made for the particular methods of procedure, and the powers of the courts. In some states the equity process is left undisturbed. In some the writ of partition, with certain modifications, still remains. Generally, however, the mode of obtaining partition is by petition to the higher courts of law. The courts of probate, too, are usually invested with the power to divide estates among heirs and devisees.

PARTNERSHIP, in law, exists when two or more persons combine their property, labor, or skill, or one or more of these, for the transaction of business for their common profit. It may be confined to a specific purpose, or a single transaction; but when not so limited by the words of the partners, or by acts which imply limitation, it is general. All persons competent to do business on their own account may enter into partnership. Generally, the partners own the property and the profits jointly; but one or more of them may own exclusively the property or capital, leaving only the profits to be owned jointly. So all kinds of property may be owned by a partnership. But when real estate is owned, the law of record title, of transfer by deed, of inheritance, and of dower, has still an important operation. Generally the rule is this: real estate is partnership property when it is bought with partnership funds, for partnership purposes, and is used for these purposes. Then it will be treated as part of the capital of the firm, and just as personal property is treated, so far as liability for the partnership debts is concerned, and until the remaining balance is ascertained and divided among the partners; but then its character as real estate is restored with all the incidents of dower and the like. The legal title must always be traced through the records. But if the property be, for example, in the name of one partner, he will be regarded as holding it in trust for the partnership; and if he die, his heir will be held as trustee, and only so much as is not wanted to pay the debts of the firm, or satisfy the claims of the other partners, will be permitted to remain in his hands, as his own and *free* from the obligations of the trust. So, the widow has her dower in the real estate after debts and claims are satisfied, and not before.—The good will of a partnership is, for many purposes, a part of its property, and may be transferred by sale or assigned for the benefit of creditors; and it would undoubtedly pass to the assignees under insolvency, by operation of law.—No partner, and no majority, can introduce a new partner without the consent of the others. A partner may sell out all his interest in a partnership, or may assign it as security for a debt; but the purchaser or assignee only acquires a right to have the balance due paid to him, and cannot acquire merely by the transfer a right to become a partner.—A partnership may be formed by an instrument under seal, which is perhaps the most common, or by a written instrument without seal, or by oral agreement, without any writing. In general, a partnership is formed by an agreement that the parties shall enter together into a certain business, and share the profits and losses. In the absence of special stipulations, the partners share equally, but may stipulate about this as they will. So the agreement may provide for its duration, but if the period appointed for its termination arrives, and it continues in fact, and without a new bargain, it will be held to continue upon the former terms.—Persons may be partners as to third persons who deal with the firm, while they are not partners as between themselves. Thus, A may agree with B and C that A shall render certain assistance to the firm of B and C, either of capital, credit, or skill, and not be held out as a partner, nor be a partner, and own a certain proportion of the profits, and not be liable for any share of the losses. Then, if the firm be not insolvent, A may claim of B and C his share of the profits, and, if obliged to pay any debt or loss of the firm, may claim compensation from B and C. But nevertheless, he will be just as liable to the creditors of the firm as B or C; and all his property will be as liable as their property. There have been many cases turning on this point, but the principle of law is clear and certain, however difficult it may sometimes be to apply it. This principle is, that whether a person is a partner in the firm in regard to the rights and obligations among the partners, depends upon the agreements they have made; but, whatever these agreements are, he is a partner as to third persons, that is, he incurs as to them all the responsibilities of a partner, in two ways, and on two grounds. One is, that he was, by his own consent, or by his own fault, held out to the world as a partner, so as to justify the creditors of the firm in dealing with it as if he were a partner; and the second is, that, without being so known or held out, he participates in fact in the profits of the concern. For it is a nearly universal rule, that one who participates in the profits, as such, is liable for the losses. The principal and most difficult question which has arisen on this subject, relates to clerks or salesmen who are paid by a share in the profits. Formerly it was held, that if such a person was paid, for example, "one twentieth part of the profits," this made him a partner, and liable as such; but if he was paid "a sum equal to one twentieth part of the profits," this was only a payment of wages, which was indeed measured by the profits, but did not make him a partner. But this technical and irrational distinction has passed away; and now the question in every such case would be: Does his bargain with the partners merely provide that his compensation shall be measured by the profits? for then he is only a person employed by the firm and not a partner; or does the bargain give him a property in the capital or in the profits? for this would make him liable as a partner. In other words, if the alleged partner has a right and property in one twentieth (or any other proportion) of the profits, while they remain undivided, he is a partner and liable as such; but if he have no such right or property, but only a claim against the firm for so much money as, upon a settlement of the firm's profits, one twentieth of them shall amount to, he is not a partner, and has none of the liabilities of that relation.—It is sometimes important to determine whether property is held by persons as tenants in common, in which case it goes to all their creditors, or whether it is held by them as partners, in which case the partnership creditors have an exclusive right to the partnership effects. Thus, A and B own a ship, each having half; they agree to buy a cargo in the same proportions, and to ship it for sale, the returns to be divided equally. They fail. If they are partners in the cargo, those whom they jointly owe for it have an exclusive claim on the returns from it. If they own it only as tenants in common, each one's half goes with the rest of his property to be divided among all his creditors. In such a case it was held that they were only tenants in common; and the general rule is, that to constitute a partnership there must be a joint purchase, from a joint fund or on a joint credit, of effects to be used in business, the account and profits to be kept separate from that of other property of the same parties, and the profits to be owned jointly.—It is a general rule, both in England and in the United States, that no partner can sue another at law on any matter growing out of and connected with the transactions of the partnership business, and dependent for its determination upon the partnership accounts. One reason for this ancient and well established rule may be, that no individual partner has any separate right or interest in any of the goods or accounts of the firm, because all are owned by all the partners jointly. But the principal reason is, that any one such question involves others which a court of law has no adequate means for investigating. For if a partner recovered on this claim against a partner, there are multitudes of other claims or accounts, on each of which another question may be raised; and whether, on the whole, one partner owed another or had a claim against him, must depend upon a settlement of all the business and an adjustment of all the accounts. This a court of equity can direct and supervise by its machinery of masters, receivers, and the like, although a court of law cannot; and therefore it is now settled, as a general rule, that questions between partners about partnership affairs must go before a court of equity and not a court of law. But a partner may sue a partner at law in any matter not involving the partnership accounts; and so if a distinct part thereof is severed from the rest, and especially if a separate promise is made about this, a common action at law is maintainable for the balance. If, as is not unfrequently the case, a man is a member of two firms, one of those firms cannot sue the other at law, because the same person cannot be plaintiff and defendant. But if one of the firms holds the negotiable paper of the other, it may indorse it to a third person, who may sue the other firm.—Partners are of various kinds. They may be open or secret, active or dormant, retiring or new-coming. A secret partner is just as liable for the debts of the firm, when he is discovered, as an open and declared partner; so a dormant partner who only lends his capital or his name, and takes his profits, is just as liable as an active partner; for the one rule, which lies at the foundation of the whole law of partnership, is, that each partner, and the whole of his property, is liable for the whole of the partnership debts. This rule was until recently a universal one, and would be so now but for the special partnership recently introduced into this country from Europe. (See PARTNERSHIP, LIMITED.) A retiring partner who continues to receive a share of the profits continues to be liable for the debts of the firm, but is not made liable by receiving a certain definite sum, annually or otherwise, independently of the profits. He should give notice of his retirement; for those who deal with the firm in ignorance of his retirement, without their fault, may deal with it on his credit, and are authorized to hold him responsible. But if the retiring partner gives such general notice in the usual way, he is not liable to a customer who happened not to know of his retirement; and a new customer, who had no dealings with the firm before the retirement of this partner, cannot hold the partner after retirement without notice, unless it can be shown that he came to the firm on the credit of this partner, and that he was justified in trusting to this credit. So if a creditor of a firm, knowing of such retirement, receives for his debt the negotiable paper of the firm, the presumption of law is that he intended to discharge the retiring partner; which presumption can be refuted only by evidence of an honest and actual intention to the contrary. A nominal partner, who lends his name to a firm without any interest whatever, is, in general, just as liable as if he were actually interested. If one purchase goods separately, and owe for them, those who become subsequently interested in the goods jointly with the first purchaser are not thereby made liable for the debt, unless the purchase was made originally by their joint authority, and for the purpose of bringing it into the partnership; for then the partnership existed at the beginning.—Throughout the commercial world, it is a universal rule, that each partner has full power and authority to act for the others and represent the whole firm in all matters appertaining to the partnership. There is perhaps no exception or limitation to this rule, other than by the principle that either partner's powers may be restrained by agreement, and all persons to whom this agreement is communicated are bound by it. Hence, on the continent of Europe, it is very common for the circulars or cards announcing a firm to state specially which of the members is authorized to make purchases in one place or in another, or to draw or accept bills, and the like. Where there is not this agreed and declared limitation, each partner may make purchases, sales, loans, assignments, pledges, or mortgages of the partnership property, and give or receive notes or bills or money therefor; and any such transaction, done in reference to and within the scope of the partnership business, and with honest intent on the part of the person dealing with the firm, binds the firm and all the partners in regard to that person, however fraudulent the transaction may be in reference to the other partners. But if a partner, who has borrowed money in his own name, brings that money into the partnership, the partners are not thereby made liable for the debt; the firm owes the borrowing partner, and he alone owes the lender; and one who lends money to a partner, for the very purpose of enabling him to contribute the same to their capital, cannot hold the other partners without their assent.—Some partnerships are carried on in the name of an individual, who may also use his own name in his own business. In that case, paper bearing his name will be supposed to relate to his private and individual business, unless direct evidence or circumstances show it to have been on the firm's account. But if a partner is a trustee for any body, and applies the trust money in his hands to the partnership account, the partners are certainly liable if they knew of this application of the trust money and did not prevent it, and, according to some authorities, even if they had no knowledge of it. A release by one partner, or to one partner, is a release by or to the firm, if there be no fraud; so a notice by or to one is notice by or to all.—The question sometimes arises, how far a new-coming member is responsible for a former and existing debt. The general answer is, that he is not so liable without his adoption of the debt; but this adoption may be shown by his express agreement, either with the firm or with the creditor, or it may be inferred from circumstances which distinctly indicate it; and it has been held that a payment by the firm, after he enters it, of the interest on an old debt with his knowledge and without objection by him, implies his adoption of the debt as due from his firm. But the liability of a new-coming partner for the existing debts of the firm cannot be presumed from the mere fact of his entering into the firm.—Whether a majority of the partners can bind a minority, and conduct the business of the firm at their pleasure, may not be quite settled; but the later authorities seem to confine this power of a majority to what may be called the domestic affairs of the firm, as the hiring a room or store, keeping clerks or books, and the like. At the same time it seems to be now well established that a partner who dissents from an inchoate and incomplete transaction, and distinctly expresses his dissent to the outside parties concerned in the transaction, giving them notice that he shall not be bound by the action of the firm, may in this way protect himself from liability. It should be added, however, that the recusant partner, after such denial and notice, may waive it, and will be considered as doing so if he permits the proceeds or avails of the transaction to be brought into the common account and the common fund for the common benefit.—The dissolution of a partnership, however caused, has no effect upon its existing debts, or upon the liability of the partners for them; but it entirely prevents the contracting of any new debt by the firm, because that has ceased to exist. Hence the former partners can in no way bind by any new contracts. Thus, no partner can indorse a note of the firm, either with the firm's name or his own, even if it be to pay a debt of the firm; and even authority given by the firm to one partner to settle the affairs of the firm would not, generally, carry with it the power to make such indorsement. Dissolution may take place in many ways. 1. By the expiration of the time when it is to terminate by the articles; but if it goes on as before, although nothing be said, the law will presume an agreement to continue it on the former terms. 2. It may certainly be dissolved at the pleasure of either partner, if there be no limited term in the articles; and if there be, and even if there be a mutual covenant not to dissolve, we should say that either partner might dissolve the copartnership at his pleasure, always being liable to respond in damages for any injury he may inflict by his breach of contract. But a court of equity would probably interfere to prevent a causeless or fraudulent dissolution, especially if it were obvious that injury would be done which could not be adequately compensated by damages. So a court of equity would always decree a dissolution at the prayer of any partner, if he could show good cause, of sufficient magnitude; and in any such case the court would appoint a receiver if that were necessary, and do or order all other things which the interests and equities of the parties required. 3. An assignment by a partner of his whole share and interest in the copartnership property and business would of itself, as we think, work a dissolution; and it would be so even if one partner assigned his whole share to another partner, because this would be equivalent to this partner's going out of the firm. 4. Any departure from a firm or copartnership by any partner dissolves that firm, however it be caused. The firm may go on as before, taking in or not new partners, but it is in law a new firm, for the simple reason that a partnership is in no sense or measure a corporation. Hence, the death of any member of a firm dissolves that firm. Even if the articles provide for that casualty, and it is agreed that the firm shall go on with unchanged name, and that no account shall be taken, but the share of the deceased be paid to his representatives by cash or notes to a certain amount, still in law the old firm ceased when the partner died, and a new one began. 5. Bankruptcy of the firm, or perhaps of any partner, dissolves the firm at once. Whether the insanity of a partner has that effect may not be certain, but we should say that insanity which would probably be permanent would unquestionably be a good ground for dissolution by the court or by the parties, but that it would not of itself, and by its own force, effect a dissolution.—If a partnership is dissolved by the death of a partner, the whole property and business pass to the survivor or survivors, but only for the purpose of settling up the business and closing the concerns of the partnership as soon as this can be done in a proper way. The surviving partners and the representatives of the deceased may come to some agreement about this, or the articles may provide for such an event. But in the absence of any such agreement or provision, the survivors take every thing, with the powers necessary for the speediest and best settlement, and no more; nor can they, even for the purpose of settlement, make new contracts binding the estate or representatives of the deceased. When the settlement is finally and fully made, the survivors must pay over to the representatives of the deceased the share due to the estate; but until then the representatives cannot interfere with the management of the property, although a court of equity will interfere, on their petition, to prevent waste, delay, or other injurious conduct by the survivors.—The rules of law in regard to the rights of creditors over the funds of the partnership, and the property of the partners, are very important, but in some particulars they are not quite settled. It is certain that the joint funds of the partnership are, in the first place, to be applied and appropriated to pay the joint debts, that is, to pay the partnership creditors; and the private creditors of the individual partners cannot touch the partnership funds in any way until these have paid in full all the partnership debts. It is also certain that the private creditors of an individual partner may reach by any proper process of law the private and separate property of the partner who is their debtor. So, too, it is certain that the creditors of the firm may, at some time, resort to the private property of the partners. The uncertainty is involved in this question: While the creditors of the firm have an exclusive right to the property of the firm, have the private creditors of the partners an equally exclusive right to the private property of the indebted partners? Formerly it was not so; and while a creditor of A, of the insolvent firm of A and B, could not touch the funds of the firm until the debts of the firm were paid and a balance found due to A, which balance his creditor might reach, it was at the same time held that a creditor of the firm could resort to the private property of A or B as freely as to the joint funds of A and B. The obvious inequality of this rule has caused some of our courts—as in New York, Pennsylvania, and New Hampshire—to give to the private creditors the same prior right to the private property, that the joint creditors have to the joint property; and the same rule is favored in England. But in most of the states, as far as we can judge from existing decisions, the old rule still continues.—What right a creditor of a partner in a solvent firm has, and how he may effectuate his right, is a matter of much uncertainty. The prevailing principle may however be stated in this way. The creditor can take only what his debtor has. This is not a several and distinct right to or property in any part of the partnership funds; for it is only an ownership of the whole in common with the other partners, and thence a right to have the accounts settled, and the debts of the firm paid, and then his share of the balance set off or paid to him in severalty. This right or interest his creditor may acquire by attachment or levy; and if it be done by attachment, a frequent and generally speaking the better way, is to summon all the partners as trustees or garnishees under the process of foreign attachment.

PARTNERSHIP, LIMITED (or, as it is sometimes called, special partnership), a partnership whereof one or more of the members contribute a certain amount to the capital, which may be lost by its being demanded for payment of the debts of the firm, but beyond which they have no further liability. This is utterly unknown to the common law, or to the law merchant as existing in England and in the United States. It has however been common on the continent of Europe for a long time. Recently it has been adopted in this country, and is now common. The following states have statutes authorizing limited partnership, and there may be others: Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Maryland, Virginia, South Carolina, Georgia, Florida, Alabama, Mississippi, Kentucky, Michigan, Indiana, Illinois. After much opposition, it has to some extent become established in England. It has made a partnership partially resemble a corporation. A stockholder in a corporation may lose his stock, but not be made liable any further, unless by special statutory provision; whereas every partner is liable *in solido* for all the partnership debts. From this liability capitalists were unwilling to place any part of their capital in a trading company, because their whole fortune would be at risk. It was thought that it would be better for the commerce of the country, that young merchants and others with skill and enterprise but not capital, should be able to induce those who had available funds to place them in the business; for then it rested on a real capital and not on mere credit or possible profit; and the capitalist, who would be entitled only to a certain portion of the profits, would be exposed only to a proportionate liability. The system is believed to have been found to work well in practice, wherever it has been introduced. The statutes of no two states, perhaps, are precisely the same; but they agree substantially in the following provisions: 1, there must be one or more general partners, all of whom are liable *in solido*; 2, there may be one or more special partners, and the specific sum contributed by each special partner must be actually paid in; 3, the arrangement or articles of partnership must be in writing, must generally be acknowledged before a magistrate, and must be published in one or more newspapers; 4, this advertisement, or publication, must state accurately the names and residences of the general partners, the names and residences of the special partners, the name of the firm, the sum which each special partner contributes, the business to be transacted, and the period for which the partnership is made or the time when it will terminate; and during that time the special partner cannot withdraw his capital. In some of the states there are provisions limiting special partnerships to mercantile business, and excluding insurance, banking, &c. If any of the requirements of law are disregarded, the special partner becomes a general partner, and is liable *in solido*. The courts apply these rules with much severity. Thus, a special partner has been held liable *in solido* because, by an error of one of the newspapers, the sum he contributed was stated erroneously; and in another case, because he sold out his interest to a general partner for more than he put in, this being considered as a withdrawal of his capital.

PARTON, JAMES, an American author, born in Canterbury, England, Feb. 9, 1822. At 5 years of age he was brought to New York, where the rest of his childhood was passed; and at 19 he became a teacher in an academy at White Plains, Westchester co., at which he had received his education. Subsequently he was occupied for several years in the same capacity at Philadelphia and New York. His first literary employment was on the staff of the "Home Journal" of New York, with which he was connected about 3 years. In 1855 appeared his "Life of Horace Greeley," of which over 30,000 copies have been sold, and which was followed in 1857 by his "Life of Aaron Burr." Of this work, the most elaborate biography of Burr yet published, nearly 20,000 copies were sold during a period of great commercial distress. His last publication, "Life of Andrew Jackson" (3 vols. 8vo., 1859–'60), in the preparation of which, as in that of the life of Burr, he had access to a mass of original documents, has proved equally successful in a pecuniary point of view. In 1856 Mr. Parton published a collection of "Humorous Poetry of the English Language, from Chaucer to Saxe." He is now (1861) engaged upon a biography of Benjamin Franklin.—SARA PAYSON WILLIS, wife of the preceding, better known by her *nom de plume* of "Fanny Fern," born in Portland, Me., July 7, 1811. Her father, Nathaniel Willis, for many years editor of the "Boston Recorder," removed to Boston with his family when his daughter was 6 weeks old, and in that city she passed her early years. Her education was received at the school of Miss Catharine E. Beecher at Hartford, where Mrs. Harriet Beecher Stowe was then a junior teacher. She was married to Charles Eldredge, cashier of the merchants' bank, Boston, with whom she lived for a number of years in affluence and happiness; but upon the death of her husband she was suddenly thrown upon her own resources to provide a maintenance for herself and two children. After unsuccessful attempts to procure employment as a teacher and in other vocations, she turned her attention in 1851 to literature, and prepared a short essay for publication, which was rejected by the editors of several Boston journals to whom it was offered. One of them at length ventured to purchase it for half a dollar; it proved successful, and was followed by a number of others, which were widely copied by the public journals, until her pseudonyme of "Fanny Fern" was familiar in all parts of the United States. A collection of these sketches was published in 1853 under the title of "Fern Leaves," of which 70,000 copies were sold in a short time. This was followed by "Little Ferns" (1853), "Fern Leaves, Second Series" (1854), "Ruth Hall," "Rose Clark," "Fresh Leaves" (1857), and "The Play Day Book" (1857), all of which have enjoyed a considerable popularity. They have all been republished in England, and some of them have been translated into French and German. For the last few years she has been chiefly employed in writing for the "New York Ledger." Soon after the commencement of her literary career she removed to New York, where she has since resided. She was married to Mr. Parton in Jan. 1856.

PARTRIDGE, the popular name of the family of *perdicidæ*, which includes also the quails. They differ from the grouse in having the legs bare and the nostrils protected by a naked hard scale; they are also smaller in size and more numerous in species; the head seldom has a naked space around the eyes, and the sides of the toes are hardly pectinated; they are widely distributed over the globe, but the true partridges, or *perdicinæ*, have no representative in America. Great confusion exists in the application of the term partridge; the spruce partridge is the Canada grouse (*tetrao Canadensis*, Linn.); the partridge of New England is the ruffed grouse (*bonasa umbellus*, Steph.); the partridge of the middle and southern states is the quail (*ortyx Virginianus*, Bonap.); several other quails are called partridges, as the plumed and Gambel's of California, the scaled or blue and the Massena of the valley of the Rio Grande in Texas; on the other hand, the birds called quails in Europe belong to the partridges and to the genus *coturnix* (Möhr.); such of the so called partridges, therefore, as are not described here will be found under GROUSE and QUAIL, and the francolin partridges under FRANCOLIN.—The typical partridges belong to the genus *perdix* (Briss.); the bill is short, broad at the base, with the apex curved and vaulted; the wings moderate and rounded, with the 3d, 4th, and 5th quills longest; tail short and greatly concealed by the coverts; tarsi without spurs or tubercles; toes long, inner shorter than outer, hind one short and slender, and claws moderate and slightly curved. There are about a dozen species in the temperate parts of the old world, some constant residents and others migratory, some frequenting cultivated lands and others forests; though occasionally perching on trees, they are generally seen on the ground, searching for grain, seeds, bulbous roots, and insects; the nest is a slight hollow on the ground, beneath some bush, and the eggs are from 12 to 20 in number. The common or gray partridge (*P. cinerea*, Lath.) is about 12 inches long, with an alar extent of 20; the body is round and stout, the head small, and the legs and tail short. Though the plumage has no brilliant colors, it is very neat, and its intricate upper markings of ash-gray, yellowish brown, brownish black, and brownish red are pleasing to the eye; the scapulars and wing coverts are darker, with whitish streaks; the forehead, cheeks, and throat light red; neck ash-gray, with minute black undulations; sides with broad bands of brownish red, and a large patch of the same on the breast. The female is a little smaller, with the upper parts browner and the top of the head streaked with yellowish; both sexes present considerable variations. It is spread abundantly over Europe, and is sometimes found in N. Africa, generally in the vicinity of grain fields and very rarely in woods; it runs with great speed, squatting close to the ground when alarmed; the flight is rapid, direct, low, and accompanied with a whirring sound; it is wary, and easily frightened; the affection for the young, or pouts, is very remarkable, and various devices are used by the parents to distract attention from the brood. During winter they keep together in coveys, searching for food among the stubble; they separate early in spring, pairing in March, the eggs being laid in June; the males take no part in incubation, but watch the nest. The genus is monogamous. This is one of the best game birds, as its flesh is tender and well flavored; shooting it forms a favorite and exciting amusement, especially in Great Britain; the bird is so prolific that, with protection during the breeding season, their numbers do not materially diminish, and the markets are so well supplied that the price brings them within the reach of the middling classes. The partridge thrives well in captivity, and its inclination to the neighborhood of man seems to indicate that with proper treatment and food it might be added to the list of domesticated birds. It is not only the victim of man, but of carnivorous mammals and birds, to the last of which it is peculiarly exposed on account of its terrestrial habits and short flight. The passenger partridge (*P. Damascena*, Briss.) is generally considered a variety of the last; it is smaller, much wilder, with greater powers of flight, and decidedly a migratory bird.—The Guernsey or red-legged partridge belongs to the genus *caccabis* (Kaup); in this the bill is more arched and the tarsi are armed with a blunt tubercle. This species (*C. rufa*, Kaup) is 14 inches long, with an alar extent of 21; the bill and feet are bright red;

upper parts reddish brown tinged with gray; a black band from the bill to the eye, and thence down the neck, becoming wider and meeting in front that of the opposite side; lower parts ash-gray and light red, and sides banded with the same and black and white. It is confined chiefly to the southern countries of Europe and to Asia and Africa; it is found also in the islands of Guernsey and Jersey; its flesh is highly esteemed, but it affords less sport than the common species from the separation of the flock when pursued by dogs; it is also believed to drive off the gray partridge. The Greek or rock partridge (*C. Græca*, Briss.) is larger than the last, and has the plumage more ashy; it inhabits the mountainous regions of Greece, Turkey, and Asia Minor, and is probably the species alluded to in the Hebrew and other ancient writings; the flesh is white and much esteemed, though it is occasionally bitter.—The genus *ithaginis* (Wagl.) has a short stout bill, lengthened and rounded tail, long tarsi armed with 2 or 3 blunt spurs, and the toes and claws long. Here belongs the sanguine partridge (*I. cruentus*, Hardw.), from the mountains of N. India; it is slate-colored above with yellow streaks, and greenish yellow below irregularly spotted with red; edge of tail coverts and vent red; it is nearly as large as a pheasant. The genus *ptilopachus* (Swains.), from W. Africa, has a small slender bill, long tail, and unspurred tarsi. The genus *lerwa* (Hodgs.) has a short and much curved bill, the sides of the upper mandible much dilated and covering the lower, wings long, tail moderate, tarsi plumed below the knee and armed with a small spur, the toes long, and claws robust. The type of this genus (*L. nivicola*, Hodgs.) is found in flocks among the rocks and brushwood near the snowy mountains of N. India; it feeds on buds and leaves of aromatic plants and on insects, and is highly esteemed as a game bird. The genus *rollulus* (Bonn.) has a short strong bill, unarmed tarsi, and moderate toes, the hind one destitute of claw. The species are found in the Indian archipelago, and the best known is the crowned partridge (*R. roulroul*, Scop.), common in Sumatra and Borneo; it is 10 inches long; bill above black, beneath orange; eyes surrounded by a naked orange skin; plumage blackish with violet and green reflections; head and neck velvet black; crown white, behind it a semicircular crest of loose reddish brown feathers, and in front of it several long bristles; the wings brownish black; under parts bluish black; shoulders, rump, and tail muddy green. The female is of a general deep green color, with dusky head and tawny brown wings, according to Latham.

PARTRIDGE, ALDEN, an American soldier, born in Norwich, Vt., about 1785, died Jan. 16, 1854. He was graduated at the U. S. military academy at West Point in 1806, and acted as assistant professor and afterward professor of mathematics in that institution from that time until 1813. He was professor of engineering from 1813 to 1818, and superintendent from Jan. 1815, to Nov. 1816, and from January to July, 1817. In 1818 he left the service, with the rank of captain. He was the principal of the exploring survey sent out in 1819 to determine the N. W. boundary of the United States. He founded in 1820 at Norwich, Vt., a military academy, which was afterward removed for a time to Middletown, Conn., but restored to Norwich and incorporated as Norwich university, with Capt. Partridge as its president. He subsequently founded similar institutions in Pennsylvania, Virginia, and Mississippi, was chosen surveyor-general of his native state in 1822, and was 5 times a member of the Vermont legislature, from 1833 to 1839.

PARTRIDGE BERRY, a smooth and trailing small evergreen herb, of the natural order *rubiaceæ*, the *Mitchella repens* (Linn.), commemorating the botanical acquirements of Dr. John Mitchell, an early correspondent of Linnæus, who resided in Virginia. This exceedingly pretty little creeping plant, very common in New England, is found in shaded woods throughout North America, growing near the foot of pine and cedar trees especially; its leaves are roundish and variegated with whitish lines upon a dark green surface; its short petioles have minute stipules; its flowers are white and fragrant, sometimes purplish tinted, and are borne in twos, succeeded by dry-pulped scarlet berries, which are slightly mucilaginous and quite tasteless, lasting throughout the entire winter. It is not unusual to find the berries of the preceding year accompanying the fresh flowers. These bright-colored berries are sometimes called two-eyes and cats'-eyes, from the circumstance of the 2 calyces marking the 2 ovaries appearing on the same fruit, which is the joint produce of the 2 flowers.—The name partridge berry is also frequently applied to the *Gaultheria procumbens* (Kalm), more commonly called wintergreen. (See WINTERGREEN.)

PARTRIDGE WOOD, a kind of wood prized in cabinet work on account of its shaded and beautiful appearance. The tree which furnishes it is unknown in the latest botanical systems, though called by Aublet *bocoa prouacensis*, who gives an account of it in his *Plantes de la Guiane Françoise* (London and Paris, 1775). He remarks that it is found in the woods of Caux, and intimates that its heartwood might be employed in making blocks and pulleys, but says nothing of its being an article of export. Guibourt, author of a notice on the indigenous and exotic trees and woods of Guadeloupe (Paris, 1836), mentions the same as being a tree growing in Cayenne to the height of 60 feet, and called there *boco*, but on what authority he does not state.

PARUTA, PAOLO, an Italian author, born in Venice in 1540, died there in 1598. He was educated at the university of Padua, and after filling several public offices was chosen historiographer of the republic. The result of his labors, embracing the period between 1518 and 1551, is included in the series called *Istorici Veneziani*. In 1592 he was sent as ambassador to Rome, and on his return to Venice was made a knight and *procuratore* of St. Mark. His principal work is entitled *Discorsi politici* (Venice, 1599), a series of disquisitions on Roman and modern history, distinguished by their impartiality, sagacity, and independent train of thought. He also published a work *Della perfezione della vita politica* (1579), a history of the Turko-Venetian war in the island of Cyprus, and valuable notes on Tacitus.

PAS-DE-CALAIS, a maritime department of northern France, formed principally from the old province of Artois, bounded N. by the strait of Dover (Fr. *Pas de Calais*), E. by the department of Nord, S. by Somme, and W. by the English channel; area, 2,505 sq. m.; pop. in 1856, 712,846. It is intersected from S. E. to N. W. by a chain of hills which give rise to several rivers, the most important of which are the Scarpe and the Lys, branches of the Scheldt, and the Aa and the Canche, flowing respectively into the German ocean and the English channel. These rivers are navigable and united by canals. The northern railway and its branches cross the department. Coal is found in small quantities. The soil is marshy in some districts, but is generally fertile. Much land is devoted to the growth of beets for the manufacture of sugar, more being raised in this department than any other except Nord. The manufacture of tulles is carried on at Boulogne and Calais; while other towns are engaged in making cotton and linen stuffs and yarns, spirits, leather, gunpowder, soap, glass, and earthenware. The chief town is Arras, formerly the capital of the province of Artois.

PASARGADA, or **Pasargadæ**, the capital of ancient Persia under Cyrus and Cambyses, and previous to the foundation of Persepolis, situated on the small river Cyrus (now Koor), in a plain surrounded upon all sides by mountains, and about the centre of ancient Persis proper. Its name is translated by Stephen of Byzantium, "the encampment of all the Persians." The modern Murgaub occupies its site, and the whole adjoining plain is strewn with its relics. Among these is a tomb called by the natives the tomb of Solomon's mother, but which is supposed by Rawlinson and others to be that of Cyrus. On a square base, composed of immense blocks of white marble, that rise in steps, stands a quadrangular house or chamber, built of blocks of marble 5 feet thick, shaped at the top into a sloping roof. The chamber seems to have held a sarcophagus. Upon pillars near by repeatedly occurs the inscription in Persian and Median: "I am Cyrus the Achæmenian." This is the exact description given in Arrian of the tomb that held the remains of Cyrus in the time of Alexander, and the existence of which at this place was vouched for by Aristobulus, one of Alexander's companions. The ancient city was esteemed by the people for its antiquity, and was under the especial protection of the magi. It contained the most ancient royal palace and the treasures. The Persian kings were inaugurated there. The city was the stronghold of a tribe of the same name, the noblest of the 3 principal tribes of the ancient Persians. The Achæmenidæ, to whom Cyrus, Darius, and other kings belonged, and who were in fact the royal family of ancient Persia, were a clan of the Pasargadæ. They were apparently the direct descendants of the original Persian tribe which emigrated from further east about 1500 B. C., and which as it rose to power imposed its name upon the people and the country.

PASCAGOULA, a river of Mississippi, formed by the junction of the Leaf and Chickahay. It flows in a southerly direction into Mississippi sound, through two separate mouths, its embouchure forming Pascagoula bay. It is navigable for 100 m. or more by small vessels, which export timber, turpentine, and other products of the pine forests through which it flows. The name is derived from that of the Pasca-ogoulas ("Bread-eaters") or Pascagoulas, a tribe of Indians formerly inhabiting the vicinity. On the E. mouth of the river is the village of Pascagoula, or East Pascagoula, which contains several hundred inhabitants and a large hotel, and is much frequented as a summer watering place. There are extensive saw mills in the vicinity.—The mouth of Pascagoula river is celebrated for the "mysterious music" which may often be heard there on still summer evenings. The listener being on the beach, or, yet more favorably, in a boat floating upon the river, a low, plaintive sound is heard, rising and falling like that of an Æolian harp, and seeming to issue from the water. The sounds, which are represented as indescribably sweet and plaintive, cease as soon as there is any noise or disturbance of the water. The actual occurrence of this phenomenon, not only at the mouth of the Pascagoula, but at other points on the same coast, is fully attested by unquestionable evidence. It is the subject of various legends and traditions, but the most plausible conjecture in explanation of its origin is that it is occasioned by some species of shell fish or other marine animal. A somewhat similar phenomenon is mentioned by Sir Emerson Tennent as occurring in certain situations on the coast of Ceylon.

PASCAL, Blaise, a French author, mathematician, and philosopher, born in Clermont, Auvergne, June 19, 1623, died in Paris, Aug. 19, 1662. His father was president of the court of aids in his native city, and was a man of considerable learning. Being left a widower, he sold his office in 1631, and removed to Paris with the intention of devoting himself to the education of his son and two daughters. He directed the studies of the son to languages and general literature, avoiding every thing connected with the exact sciences. This only sharpened the desire of the boy, now 12 years of age, for the forbidden studies. Without assistance, and ignorant even of the very rudiments of mathematics, he secretly applied himself to drawing and reflecting upon geometrical figures, until he had gone through a series of definitions, axioms, and demonstrations that brought him as far as the 32d proposition of Euclid. His father, discovering him one day engaged in these studies, was affected to tears, and, obeying what he considered a providential warning, willingly gave him mathematical instruction. Blaise made wonderful progress in this new career; he was soon admitted to the meetings of scientific societies, where his attainments and genius astounded the most learned; and at the age of 16 he composed a "Treatise on Conic Sections," which Descartes, to whom it was submitted for examination, could not believe to have been written by a mere boy. Unfortunately the manuscript has been lost. In 1639 Blaise accompanied his father to Rouen, where the latter had been appointed superintendent of finance for the province of Normandy; and there he invented a calculating machine, which was subsequently improved by L'Épine and Boitissendeau, but it never came into practical use. He published an account of it in 1645 in pamphlet form, with a dedication to Chancellor Séguier, and in 1650 offered it to Queen Christina of Sweden, in a letter which has been frequently reprinted. It was also during his stay in Rouen that he invented the *vinaigrette* (wheelbarrow chair), the *haquet* (a kind of dray), and, according to some, the hydraulic press. His health, which had never been strong, was seriously impaired by his labors, and his subsequent life was a succession of sufferings. From 1646 to 1648 he executed on the Puy-de-Dôme, near Clermont, at Rouen, and at the tower of St. Jacques-la-Boucherie in Paris, a series of barometrical experiments, which went far to confirm the discoveries of Galileo, Torricelli, and Descartes respecting the weight and elasticity of air. Pascal was led by these experiments to use the barometer as an instrument for levelling, and for ascertaining the pressure of fluids upon the sides of the vessels containing them, and establishing the laws of their equilibrium. His *Expériences touchant le vide* were published in 1647, and were assailed by Father Noël, a Jesuit, who presented himself as the champion of the old system, and whom Pascal answered in two letters. About this period he had a stroke of paralysis by which he for a while lost the use of his legs; at the same time he studied intensely devotional works, and his mind became deeply impressed with religious convictions. He was advised by his physicians to seek for diversion in society, as the only means of alleviating his sufferings. To this he reluctantly consented; but he soon allowed himself to be carried too far by his naturally ardent temperament, and his pious sister Jacqueline, who had joined the community of Port Royal, several times thought it necessary to warn him against worldly pleasures. Her entreaties would perhaps have proved unavailing, had it not been for an incident which occurred in Oct. 1654. While driving over the bridge across the Seine at Neuilly, the two forward horses attached to his carriage were precipitated into the river, and it was little less than a miracle that the carriage did not follow them. The shock he then experienced produced an effect upon his nerves and mind, from which he appears to have never entirely recovered, and to the end of his life he was subject to hallucinations and visions. The immediate result of this occurrence was to revive his religious impressions; he withdrew from society, and entered upon a course of self-denial and austerity, which characterized the remaining years of his life. Amid his previous gayeties, however, he had written some of his philosophical works, such as his treatises *De la pesanteur de la masse de l'air* and *De l'équilibre des liqueurs*, which were not published until the year after his death. In 1654 he completed an "arithmetical triangle," by which he aimed at expounding mathematically certain laws connected with bets and games of chance. It was in fact an approach toward the binomial theorem of Newton. After his death 3 treatises of his were published (1665) in which he had laid down the principles of the calculus of probabilities.—For several years Pascal had been acquainted with the Port Royalists, and his new mode of life brought him into closer intimacy with them. They were now the upholders of the doctrines of Jansenius, and though he never formally joined their society, he frequently visited their house, and soon interested himself in their quarrel with the Jesuits. When, at the end of 1655, Antoine Arnauld was expelled from the Sorbonne on account of his letter in defence of Jansenism, Pascal, impelled by motives of friendship, entered the lists and published the first of the series of *Lettres de Louis de Montalte à un provincial de ses amis et aux RR. PP. les Jésuites sur la morale et la politique de ces pères*, which afterward became so celebrated under the abbreviated title of "The Provincial Letters." The first of these letters, which appeared Jan. 23, 1656, was eagerly read and circulated even among those who had until then remained uninterested in the contest. It was followed at intervals by 17 others within a period of 14 months. The replies of the Jesuits, the condemnation of the letters by the holy see in 1657, and the sentence of the council of state and the parliament of Aix that they should be burned by the hand of the executioner, could not check their popularity; and 20 years later, as appears from Mme. de Sévigné's correspondence, the *Petites lettres*, as they were now styled, had lost nothing of their original attractions. They may be said to have been the origin of that hostile feeling which, a century later, brought about the expulsion of the society of Jesus from France. Their circulation in Europe was increased by translations into several languages; and one of the Port Royalists, Nicole, who had been instrumental in their composition, produced a Latin version of them under the name of Wendrock.—In the midst of these labors Pascal's health had continued failing, and his sufferings scarcely left him any respite; he nevertheless returned to his wonted pursuits, and studied the properties of curves, and especially those of the cycloid or *roulette*, which had already arrested the attention of Galileo, Torricelli, Descartes, and Fermat. Pascal completed their researches upon this particular point, and in 1659 published the results of his investigations in his *Traité général de la roulette*. He had also engaged in the composition of a new demonstration of Christianity, in which he was to enlist all the powers of human reason in the service of truth; but the state of his health left him but brief periods for this project. He was able only to write occasionally detached thoughts, which were collected after his death, and published in 1670, under the title of *Pensées sur la religion*. Modern critics, especially Victor Cousin and Ste. Beuve, availing themselves of previously neglected sources of information and original manuscripts too slightly passed over by former editors, have succeeded in giving an outline of Pascal's design. The last 4 years of his life were an almost unbroken series of bodily suffering and charitable employments; his alms absorbed more than his income. His remains were buried in the church of St. Étienne du Mont, where his tomb is still to be seen.—There are two editions of Pascal's complete works, including his scientific treatises, namely, that of Bossut (5 vols. 8vo., 1779), and that of Lefèvre (5 vols. 8vo., 1819). The *Lettres provinciales*, collected for the first time in 1657, were published in 1684 at Cologne under the supervision of Nicole, with Latin, Spanish, and Italian translations. The *Pensées*, which have been of late an especial object of research and study, were reprinted from the original edition of 1670, first in 1672 (2 vols. 12mo.), and with a life of Pascal by his sister, Mme. Périer, in 1684; by Desmolets, with some additions, in 1729; and by Condorcet in 1776. These were the foundation of every subsequent edition, until 1842, when M. Cousin, in a paper read before the French academy, pointed out the alterations and omissions in every one of them, referring at the same time to the autograph manuscript which is preserved in the imperial library at Paris. In 1844 M. Prosper Faugère, following up Cousin's suggestions, issued a more correct edition of the *Pensées, lettres et fragments de Blaise Pascal* (2 vols. 8vo.). This gave rise to a controversy respecting the work itself and what has been styled the scepticism of Pascal, to which we are indebted for the following works among others: Victor Cousin's *Blaise Pascal* (1849); Ste. Beuve's *Port Royal* and *Portraits littéraires;* and the abbé Flottes and A. Vinet's *Études sur Pascal* (1846 and 1848). The controversy has been summed up by Havet in a new edition of the *Pensées* (2 vols. 8vo., 1852). The life of Pascal by Mme. Périer has been the foundation of numerous subsequent biographies. The *Pensées* and *Lettres provinciales* have been several times translated into English.—The younger sister of Pascal above alluded to, JACQUELINE, born in 1625, died in 1661, left some miscellaneous works, letters, and verses, which have been collected by Prosper Faugère (1 vol., Paris, 1845), and by Cousin in his biography of Jacqueline Pascal (Paris, 1849).

PASCHAL II., pope (RANIERI OF BLEDA), born in Tuscany, died in 1118. He was a monk of the order of Cluny, and having been sent to Rome on some affairs of his order was made cardinal by Pope Gregory VII. He succeeded Urban II. in 1099, and almost immediately afterward renewed the struggle with the German emperor on the subject of investitures, which had engrossed so much of the pontificates of his predecessors. He excommunicated Henry IV. in 1102, whereupon that emperor's son revolted and caused himself to be acknowledged as Henry V.; but in the matter of investitures he proved as unyielding as his father. Paschal proposed a compromise, offering to restore all the temporalities which the church had received from secular princes since the time of Constantine, provided the emperor would renounce the right of investiture which was founded upon these grants; but the bishops, especially those of Germany, who were possessed of large fiefs, would not consent to the measure, and when Henry arrived at Rome to be crowned in 1110 the negotiation was broken off, and the pope refused to perform the coronation ceremony. The emperor thereupon seized the pontiff's person, treated him with great indignity, and after keeping him prisoner two months extorted from him a renunciation of the disputed right, received the crown, and went back to Germany. Paschal afterward summoned a council in the church of St. John Lateran, by which the investiture of churchmen by lay hands was solemnly condemned. The result was a rebellion of some of the turbulent German barons, but Henry soon subdued them, and marching upon Rome compelled the pope to flee to Benevento. After the emperor's return, Paschal made vigorous preparations for war, but died before he could take the field. He had also been involved in a dispute with Henry I. of England on the same subject, but a compromise was effected in 1108, whereby the king surrendered an unimportant part of the ceremony of investiture (the collation of the ring and crosier), and retained the right of nominating bishops and abbots and exacting from them fealty and homage.

PASHA, a Turkish governor of a province, or military and naval commander of high rank. The French spell the word *pacha*, and formerly in English it was usually written basha or bashaw. Pashas of the first rank are called pashas of 3 tails, that number of horse tails being carried before them as a standard when they appear in public. Before those of inferior rank two horse tails are borne. The title is probably of Persian origin, and is very ancient, a similar term, *pakha*, being used in the Hebrew Scriptures to designate the viceroys or governors of provinces of the Assyrian, Babylonian, and old Persian empires. The office corresponds to that of the ancient Persian satraps. Until recently the Turkish pashas were entirely absolute in the administration of their provinces, but under the present reformed system the power of these officers is in some measure checked by local councils. The province governed by a pasha is called a pashalic.

PASIPHAË. See Minos.

PASKEVITCH, Ivan Fedorovitch, prince of Warsaw, a Russian field marshal, born in Poltava, May 19, 1782, died in Warsaw, Feb. 1, 1856. He was educated at St. Petersburg, became a page of the emperor Paul, and in 1800 entered the army. He served with distinction in the earlier campaigns of the reign of Alexander I., and in those of 1812–'14 commanded under Bagration, Miloradovitch, Benningsen, and Rayevski, at Smolensk, Moscow, Leipsic, and in France. After his return to Russia he accompanied the grand duke Michael, brother of the emperor, on a journey through various provinces of the empire; and in 1826, on the outbreak of the war against Persia, was appointed by Nicholas to command under Yermoloff. Having achieved considerable successes over the Persians under Abbas Mirza, he in the following year succeeded the less successful Yermoloff in the chief command; and the taking of the fortified Armenian convent of Etchmiadzin, of Nakhitchevan, and other strong places, soon paved the way to the conquest of Erivan, which capitulated in Oct. 1827. For this achievement he was rewarded by Nicholas with the title of Erivanski. Paskevitch now crossed the Aras, and by a rapid advance entered the city of Tabriz, when a peace was concluded with the Persian commander, but it was not ratified until after further operations in the beginning of 1828. The peace of Turkmantchai, which added to Russia Persian Armenia, being concluded Feb. 22, Paskevitch found a new field of military activity in the war against Turkey. He commanded in the East, while the principal Russian army was engaged on the line of the lower Danube and the Balkan. Anapa, Poti, Kars, and Akhaltzik were taken in the summer of that year; and advancing through mountain passes in that of 1829, Paskevitch surprised a large army under the seraskier. Assisted by the treachery of the janizaries, he took Erzroum, July 8, and pushed forward toward Trebizond, in the vicinity of which he received the news of the peace of Adrianople. Made field marshal and governor of the province of Georgia, he checked the rising of the Lesghian mountaineers in 1830, and in the following year, on the death of Diebitsch, was appointed (June 26) his successor as commander-in-chief of the armies employed in Poland. These were at the same time strengthened so as to become overwhelming; and, still deluded by the promises of France, the generals of the revolution allowed Paskevitch to cross the Vistula, unchecked, near the Prussian frontier, and to advance on the right bank of that river toward Warsaw, which after a desperate struggle finally capitulated (Sept. 8). The conqueror received as his reward the title of prince of Warsaw, and was made governor (Russ. and Pol. *namiestnik*, lieutenant or viceroy) of Poland, which was now stripped of its constitutional semi-independence, and transformed into a Russian province, though maintaining some institutions of a separate administration. The task of governing the unhappy country was one of the greatest responsibility; but Paskevitch not only discharged his duty to the entire satisfaction of his master, but by his moderation also gained some popularity among the less revolutionary part of the Polish people. Various attempts at a new rising, among others that of 1846, were speedily suppressed; and the year 1848 passed off without convulsion, the attention of the Poles being chiefly turned toward Hungary, whence the liberation of Poland was expected. To avert the more and more threatening danger, Nicholas, having already attempted an invasion of Hungary from the Danubian principalities in the winter of 1849, in the ensuing spring placed Paskevitch at the head of an army of intervention of more than 200,000 men, which simultaneously crossed the northern, north-western, and south-eastern Carpathians, acting in part independently, and in part in conjunction with the Austrians. No brilliant victory was now achieved by Paskevitch, his principal merit consisting in cautiously avoiding dangers, while the Hungarians, distracted by hostile populations and fortresses within their own territory, were slowly crushed by the weight of converging masses. Görgey's surrender at Világos (Aug. 13) having virtually ended the struggle, Paskevitch returned to Warsaw, where he received new honors from Nicholas. A grand jubilee soon after took place in that city on the 50th anniversary of his entrance into the army. In April, 1854, he once more took the command of the principal Russian army in the war against Turkey, after the first disastrous campaign on the Danube, but soon resigned it, having been wounded before Silistria (June 8), which he failed to conquer, and returned to Poland. His successor in command, Prince Michael Gortchakoff, also succeeded him as governor of that country.

PASQUIER, Étienne, a French jurist and author, born in Paris in 1529, died Aug. 31, 1615. He studied law under Cujas at Toulouse and Marianus Socinus at Bologna, was admitted to the bar, and first appeared in 1549 in the capacity of attorney before the parliament of Paris. He devoted much attention to literature and history, and after publishing the *Mo-*

nophile and *Les colloques d'amour*, in prose, and several miscellaneous poems, he produced in 1561 the 1st book of his *Recherches de la France*. In 1564 he was counsel for the university in its lawsuit with the society of Jesuits. His pleadings made him popular, and clients flocked to him. He witnessed the parliamentary sessions known as *les grands jours* at Poitiers in 1579, and at Troyes in 1583; was in 1585 appointed attorney-general to the court of accounts, and in 1588 was elected a deputy to the states-general at Blois. A faithful adherent of royalty, he accompanied the royalist members of the parliament who, under Henry III., held their sessions at Tours, and returned to Paris with Henry IV. He now found himself involved in new quarrels with the Jesuits, who were expelled from France in consequence of the attempt of Jean Châtel upon the life of the king. In 1604 he resigned his office of attorney-general to his eldest son, and devoted his later years to revising, completing, and publishing his literary works. Most of these were collected and printed in 2 vols. fol. (Amsterdam, 1723). Beside his invaluable *Recherches de la France* in 9 books, which, notwithstanding some errors, are justly regarded as a treasury of learning, they include 22 books of familiar letters, affording ample information upon the manners of the time. M. Léon Feugère has edited his *Œuvres choisies* (2 vols. 18mo., Paris, 1849), with an excellent biographical and critical notice. Pasquier's fame as a jurist has been fully vindicated by the publication of his *Interprétation des Institutes de Justinien*, edited by M. Charles Giraud (4to., Paris, 1847).

PASQUIER, ÉTIENNE DENIS, duke, a French statesman, of the same family with the preceding, born in Paris, April 22, 1767. Before he became of age he was appointed councillor in the parliament of Paris. His father was beheaded during the French revolution, and he himself was incarcerated. Under the empire he became successively master of requests in the council of state, councillor, *procureur général du sceau et des titres*, and prefect of police. Charged by Napoleon with neglect of duty at the time of the conspiracy of Malet in 1812, he was acquitted on trial, and kept in office until the first restoration, when Louis XVIII. appointed him director-general of roads and bridges. He stood aloof during the Hundred Days, and after the second restoration was keeper of the seals and temporarily minister of the interior in the cabinet of Talleyrand in 1815, minister of justice in that of Richelieu in 1817, and of foreign affairs in that of Decazes in 1819. He adhered to the revolution of July, 1830, and was treated with favor by Louis Philippe, who made him president of the chamber of peers, with the honorary title of chancellor of France. He had been made a baron by Napoleon, became a count under the restoration, and finally in 1844 received the title of duke from Louis Philippe. Although he cannot be styled an author, having published nothing but a vaudeville and a collection of discourses delivered in his capacity of minister or peer from 1814 to 1836 (4 vols. 8vo., 1842), he was in 1842 elected a member of the French academy. It is generally reported that he has written interesting *Mémoires* which will be published after his death. The revolution of 1848 terminated his political career.

PASQUIN, the name given to a mutilated statue in Rome, standing at the end of the Braschi palace near the Piazza Navona. In its immediate neighborhood was situated in the latter half of the 15th century the shop of a tailor named Pasquin, or Pasquino, which was much frequented by people of consequence for the purpose of hearing the current gossip and scandal of the town, and of amusing themselves with the facetious stories and satirical remarks of Pasquin and his workmen, to whom the utmost license of speech seems to have been allowed. So many caustic personalities emanated from this place, that gradually every bitter saying was attributed to Pasquin or his shop—a practice the more convenient, as etiquette forbade the sufferer by such libels, or pasquinades as they were called, to exhibit any resentment. After Pasquin's death the statue, which had long lain half imbedded in the ground, was dug out and set up near his shop. The populace, availing itself of this circumstance, declared that Pasquin had come to life again. The mutilated torso was called by the name of the defunct tailor, and thenceforth the custom arose of attaching to it bits of writing of a satirical character, which frequently took the shape of lampoons upon persons in high station, the pope and cardinals being favorite objects of attack. "The free speech," says a recent writer, "which was prohibited and dangerous to the living subjects of the temporal power of the popes, was a privilege which, in spite of prohibition, Pasquin insisted upon exercising. Whatever precautions might be taken, whatever penalties imposed, means were always found, when occasion arose, to affix to the battered marble papers bearing stinging epigrams or satirical verses, which, once read, fastened themselves in the memory, and spread quickly by repetition. He could not be silenced. 'Great sums,' said he one day, in an epigram addressed to Paul III., who was pope from 1534 to 1549, 'great sums were formerly given to poets for singing: how much will you give me, O Paul, to be silent?'" The statue of Marforio, supposed to be that of a river god, which about the close of the 16th century was placed in the *palazzo de' conservatori* on the Capitol, was made the vehicle for replying to the attacks of Pasquin; and other statues in various parts of the city occasionally issued an epigram on public affairs. Pasquin, however, maintained his supremacy over all rivals, and so formidable did he become that Adrian VI. proposed to have him thrown into the Tiber, but was dissuaded by his friend Lodovico Suessano, who declared that the frogs of the river would thenceforth croak pasquinades. The first true pasquinades date from the pontificate of Leo X., and after the lapse of 3½ centuries the statue pursues his ancient avocation with undiminished vigor. Satirical epigrams however were published previous to Leo's accession, and the following, directed against Alexander VI. (Roderic Borgia), is unsurpassed in severity by any utterance of Pasquin:

Vendit Alexander claves, altaria, Christum;
Emerat ille prius, vendere jure potest.

"Alexander sells the keys, the altars, Christ.
He bought them first, and has a right to sell."

PASQUOTANK, a N. E. co. of N. C., bordering on Virginia, and bounded N. E. by the Pasquotank river, and S. by Albemarle sound; area, about 300 sq. m.; pop. in 1860, 8,940, of whom 2,983 were slaves. Its surface is low and level, including a portion of the Dismal swamp, and in some places fertile. The productions in 1850 were 624,575 bushels of Indian corn, 19,436 of wheat, and 22,946 of oats. There were 3 ship yards, 3 newspaper offices, 14 churches, and 640 pupils attending public schools. The Pasquotank river is navigable for small vessels to the capital, Elizabeth City, and a branch of the Dismal Swamp canal crosses the county.

PASSAIC, a N. co. of N. J., bordering on N. Y., bounded S. W. by the Pequannock, and intersected by the Ringwood, Ramapo, and Passaic rivers; area, about 220 sq. m.; pop. in 1860, 29,021. Its surface is diversified and the soil generally fertile. The productions in 1850 were 140,213 bushels of Indian corn, 41,509 of rye, 79,169 of potatoes, 41,446 of oats, 11,025 tons of hay, 5,320 lbs. of wool, and 238,470 lbs. of butter. There were in the latter year 16 grist and 21 saw mills, 1 card, 1 carpet, 4 woollen, and 10 cotton factories, 4 paper mills, 1 rolling mill, 7 forges, 2 founderies, 1 furnace, 2 locomotive manufactories, 27 churches, and 1,157 pupils attending public schools. The Morris canal and New York and Erie railroad intersect the S. E. corner of the county, the latter passing through the capital, Paterson.

PASSAIC, a river of New Jersey, which rises in Mendham, Morris co., flows S. for a few miles and then E. between Somerset and Morris cos., then N. N. E. between the latter and Essex co., crosses Passaic co. in an easterly direction, and turning to the S. after a very devious course of about 90 m. enters Newark bay. It is navigable a short distance for sloops. At Paterson it has a fall of 72 feet (or 50 feet perpendicular), affording immense water power, which has been improved by dams and canals. It is much visited by tourists.

PASSAMAQUODDY BAY, a body of water between the S. E. extremity of Maine and the S. W. corner of New Brunswick, being about 12 m. long and 6 m. wide at the entrance. It receives the waters of the St. Croix and Didgeguash rivers. Campobello island lies across the entrance of the bay, and Deer island and a cluster of small islets called Wolf islands lie within it. The bay is well sheltered and not liable to be obstructed by ice; and it has good harbors and a sufficient depth of water for the largest vessels. It abounds with fish, such as mackerel, cod, and herring. The tide has an average rise of 25 feet.

PASSAU (anc. *Batava Castra*), a town of Bavaria, capital of the circle of Lower Bavaria, situated at the confluence of the Inn and the Danube, 92 m. E. N. E. from Munich; pop. 11,000. It is divided by the rivers into 3 parts, the central one being the town proper, and the others, Innstadt on the Inn, and Ilzstadt on the Danube, being suburbs. The Ilz, a tributary of the Danube, flows between Ilzstadt and Anger. The town is strongly fortified by two formidable castles and 8 smaller works of defence, and constitutes one of the most important strongholds on the Danube. It has a cathedral with some interesting monuments, a public library, a theatre, an old abbey, a bronze statue of King Maximilian Joseph, several schools and hospitals, a lunatic asylum, manufactures of porcelain, leather, tobacco, beer, paper, iron, and copper, and an active trade on the Danube. Its bishops were formerly independent princes, but it was secularized in 1803, and incorporated with Bavaria in 1805. In 1552 a treaty guaranteeing religious freedom to the German Protestants was concluded here between the emperor Charles V. and Maurice of Saxony.

PASSENGER PIGEON, or WILD PIGEON (*ectopistes migratoria*, Swains.), a well known columbine species peculiar to North America, where it exists in immense numbers. The family characters are given under PIGEON; the generic characters are, a very small head, short bill, long wings, the first primary the longest, tarsi very short, and tail very long and wedge-shaped. The male passenger pigeon is about 16½ inches long, with an alar extent of 25; the general color above is grayish blue, some of the wing coverts being marked with black spots; throat, fore neck, breast, and sides light brownish red, and the rest of the under parts white; lower hind neck with golden, green, and violet reflections; quills blackish, bordered with pale bluish, the larger coverts whitish at the tip; 2 middle tail feathers black, the others pale blue at the base, becoming white toward the end; the bill black, iris bright red, and feet carmine purple. The female is smaller, and of duller colors. Their rapid and long continued flight enables them to pass over, and their keen vision to survey, a vast extent of country, when migrating at irregular periods in search of the mast which constitutes their principal food; the flight is high or low according to the unfavorable or promising nature of the region; they present a very beautiful appearance as they perform their aërial evolutions preparatory to alighting, now displaying a brilliant sheet of azure which suddenly changes into rich deep purple; for an account of the rapidity of their flight, see CARRIER PIGEON.

After feeding they settle on the trees to rest, and toward sunset depart for their roosting places, often hundreds of miles distant; they build in forests where the trees are high, without much reference to season, and in places where food is abundant and water not far off; the habits of courtship, incubation, and feeding of the young squabs, are the same as in other pigeons; the flesh is dark-colored, and highly esteemed as food; according to Wilson they lay only one egg, but Audubon says two. This bird is found throughout temperate North America to the high central plains. Their numbers are absolutely countless both in the roosting and breeding places; in the former they spread over thousands of acres in the West, breaking down the limbs of trees with their weight, and destroying the grass and underwood; in these places they are killed by myriads, and by every conceivable kind of weapon and device, from clubs to firearms and sulphur pots. The breeding places are still more extensive; Wilson describes one in Kentucky as extending 40 miles through the woods and several miles wide, every tree bearing nests wherever they could be placed; they appeared about April 10 and left with their young before May 25; when the young were nearly full-grown, the people came, with their families, from all the neighboring country, formed encampments, and commenced the business of collecting the birds; he describes the scene as very exciting, though disgusting, the ground being strewed with felled trees and broken branches, the young birds devoured by hogs below and by hawks and vultures in the air, and the old birds crowding and fluttering with a deafening noise. Notwithstanding the immense destruction, such is their fecundity from the numerous broods in a season, that the numbers do not seem to diminish. Wilson calculates the length of a column of these birds which passed over him at 240 miles, and estimates the number of pigeons in it at more than 2,000,000,000; allowing ½ pint of food for each bird, such a legion would consume daily about 17,500,000 bushels. Nothing comparable to such flights, which actually obscure the sun at noonday, can be seen except in the myriads of locusts in the East. Audubon estimates the numbers at a less amount than Wilson. Though not found in such multitudes in the New England and middle states, great numbers are caught in spring nets in the autumn, keeping the market well supplied, and at a moderate price when the consumer is brought into immediate relation to the captor.

PASSION FLOWER, a showy plant, the type of the natural order *passifloraceæ.* These are herbs or shrubs, usually climbing, seldom erect, with alternate leaves furnished with leafy stipules, and the petioles often glandular; axillary or terminal flowers, often accompanied by a 3-leaved involucre; the sepals 5, of a green color; the petals 5, arising from the throat of the calyx, and colored; within these, several rows of filamentous processes, regarded by some as abortive stamens and by others as the true corolla, but probably an intermediate condition of both; the true stamens 5, monadelphous, rarely indefinite, surrounding the stalk of the ovary; anthers linear, 2-celled, bursting longitudinally; ovary upon a long stalk, superior, 1-celled; styles 3, arising from the same point, clavate; stigmas dilated; seeds attached in several rows to the placenta, with a brittle sculptured testa surrounded by a pulpy aril; cotyledons flat, leafy. The common passion flower (*passiflora cœrulea*, Linn.) is a climbing greenhouse plant from Brazil and Peru, and has been known in cultivation since 1699. Its stem is of a somewhat woody texture, and attains to considerable size; its branches are abundant, long, flexible, and of rapid growth, reaching 15 or 20 feet in a single season. Its leaves are palmate, 5-parted, and entire, the footstalks glandular; the involucre is 3-leaved; the blossoms of a beautiful blue color without and purplish and white within; the filamentous processes of the same color and shorter than the petals; they possess a faint smell, and last for a single day only; the fruit is egg-shaped, of the size of a large plum, yellowish when ripe, and filled with a sweetish unpleasant pulp and black seeds. The racemose passion flower (*P. racemosa*, Sims) is a native of Brazil, having 3-lobed leaves, with 4 glands upon the petiole, and twin pedicels forming terminal racemes in consequence of the upper leaves being abortive; its flowers are of a deep red or scarlet color. Between these two species a showy hybrid has been raised, known as *P. cœruleoracemosa* of Sabine, and described and figured in the "Transactions of the London Horticultural Society," vol. iv., in a highly interesting and scientific paper. The Grenadilla vine (*P. quadrangularis*, Willd.), a native of the West Indies, has a square ligneous stem; oblong-ovate, subcordate, entire, veiny leaves 5 to 6 inches long, petioles with 6 glands, stipules roundish ovate, involucre 3-leaved; the flowers are large, showy, red within, white without, and odoriferous; the fruit large, oblong, about 15 inches in circumference, of a greenish yellow color when ripe, soft and leathery to the touch, and quite smooth, with a very thick skin enclosing a succulent, purple pulp, of a sweet taste, but slightly acid, and in a hot climate cooling and agreeable; the seeds lie in a sort of sac which easily separates from the pulp. In the stove or hothouse this species grows admirably when trained under the rafters of the house, the shoots being pruned back to within 2 or 3 eyes of the old wood, and abundance of water given in the growing season. It has been successfully cultivated in Europe for the sake of its fruit. The winged-stem passion flower (*P. alata*, Willd.), has a 4-angled stem; undivided, cordate, very entire leaves, petioles with 4 glands; flowers large, of a rich crimson; the filamentous processes variegated with blue and purple; blossome superb, and with a pleasant scent. It succeeds admirably when trained in an upright manner at the back of the greenhouse. The serrate-leaved passion flower (*P. serratifolia*, Bot. Mag.) is a species requiring the heat of the stove, a native of Surinam, with undivided ovate-serrate leaves, showy flowers of a purplish color, the processes spotted with purple and blue. The edible passion flower (*P. edulis*, Linn.) has smooth, 3-lobed, serrated leaves, the petiole with 2 glands near the apex, the involucre glandularly serrated, the processes equal in length to the calyx; the petals whitish tinged with purple. It is a native of Brazil, grows rapidly, and is easily raised in the conservatory by training its long flexile branches to the rafters. The fruit has a yellow pulp of a peculiar flavor, esteemed by some. There are a few species which possess a disagreeable odor when the stems or glands are bruised, and which constitute a section by themselves called *dysosmia* by Don. Of these may be mentioned the *P. fœtida* of Cavanilles, having hispid stems and petioles; leaves villous on both sides, 5-nerved, cordate at the base, 3-lobed, nearly entire, lateral lobes very short, the middle ones acuminated; flowers whitish with variegated blue and purple processes. This species occurs in the Caribbean islands and in South America. A more remarkable one is the *P. ciliata* (Aiton), with a round smooth stem, which climbs to a great height; dark green, glossy, perfectly smooth, 3-lobed leaves, beset on the edges with strong glandular hairs; the involucre 3-leaved and capillary, each division terminating in a viscid globule, which is fetid when bruised; flowers small, whitish, with blue filamentous processes. From the tropical species a good many very fine hybrids have originated, of which may be mentioned *P. Kermesina*, *Loudoni*, *Decaisneana*, &c. The last named is a very recent sort, of the style of the *alata*, with leaves 10 inches long, light brilliant green, and of a coriaceous texture; large flowers of a rich crimson, with purple and blue processes.—Of the North American species, the flesh-colored (*P. incarnata*, Linn.) is common in the southern states, blooming in June and July. It has palmately 3-lobed, acute, serrate leaves, biglandular petioles, 2-bracted peduncles, sepals and petals whitish within, processes in 5 rows of a purplish pink color; fruit yellowish. It is a perennial herbaceous species, making strong shoots in a single summer, and well adapted to cover trellises in small gardens. The yellow-flowered (*P. lutea*, Linn.) has cordate leaves broadly 3-lobed at the summit, with the lobes round and entire, glandless petioles, small yellowish green flowers, and oval purple fruit; it occurs in woodlands and thickets from Ohio to Florida. The *P. suberosa* (Linn.) has smooth leaves, slightly fringed on the margins, 5-nerved at base, divided above the middle into 3 ovate, entire, acute lobes, the middle largest; petioles short, 2-glandular; flowers and sepals greenish, petals none, processes purple at base, fruit purple; it occurs in Florida. The narrow-leaved (*P. angustifolia*, Swartz) has leaves either entire or 3-lobed, the upper ones simple, lanceolate, and acute; the flowers are small, solitary or by pairs, yellowish, processes in 2 rows; fruit purple and of the size of a pea. Another species, the *P. Warei* of Nuttall, has very small flowers with a very few processes; it occurs in S. Florida, and may be a variety of *P. pallida* of the West Indies. (Chapman, in "Flora of the Southern United States," New York, 1860.)—The *passifloræ* are American species exclusively, generally occurring within or near the tropics. Although, as has been noticed, the fruits of some are edible, yet those of others are noxious and disagreeable. The prevailing quality of the genus is narcotic. The root of the Granadilla is likewise an emetic, and from the flowers of the *P. rubra* a tincture is prepared as a substitute for opium; the flowers of the *P. fœtida* are pectoral and employed in hysteria, its leaves are emollient and narcotic, and emmenagogue qualities are ascribed to the root of the plant. The aril of the seeds of some of the edible-fruited species is in some instances sweet, and in others acid and useful for compounding a cooling drink in fevers and in bilious disorders. The flowers were supposed to represent the sufferings or "passion" of the Redeemer, and in them the Spanish monks supposed they saw the figures of the implements, wounds, and crown of thorns; the trivial name thus early applied by them has been retained, affixed to a blossom which seems rather to present in its evanescence and rays of glory the type of human life.—Of the true passion flowers Don gives at least 185 species and varieties, beside mentioning many allied genera. The several kinds are easy of cultivation from seeds, suckers, or cuttings; the last should be from the extremities of the branches, and struck in a gentle heat. The soil they prefer is a light rich mould.

PASSION WEEK, in the church of England, the week before Easter, corresponding to Holy Week in the Roman Catholic church. See HOLY WEEK.

PASSOVER (Heb. *pesaḥ*, from *pasaḥ*, to leap over, to pass by; Aram. *pasha*; Sept. *πάσχα*; Vul. *pascha*), a Hebrew festival, instituted by Moses in commemoration of the Israelites remaining intact on the night of the destruction of the first born in Egypt, immediately preceding the exodus from that country (Ex. xii.). Originally it was observed by sacrificing passover lambs toward the evening of the 14th of the 1st Hebrew spring month (now Nisan), and eating them on the following night, as well as by excluding all leaven from the meals of that evening and the following 7 days, the first and last of which were observed as holy. Since the final destruction of the temple of Jerusalem, the passover has been celebrated by eating unleavened bread during the 7 (out of Palestine during 8) days, by abstinence from labor on the first and last (out of Palestine on the first two and last two), and by the observance on the first evening (out of Palestine on the first and second) of various domestic rites commemorative of the deliverance from Egyptian bondage, including the recital of scriptural and legendary narratives and familiar conversation on the same national event, and the chanting of psalms.

PASSOW, Franz Ludwig Karl Friedrich, a German philologist, born in Ludwigslust, Sept. 20, 1786, died in Breslau, March 11, 1833. He was educated at the gymnasium of Gotha and at the university of Leipsic, where he studied theology and philology. In 1807 he became professor of the Greek language in the gymnasium at Weimar, and in 1810 director of the institution styled the Conradinum at Jenkau near Dantzic. After the dissolution of this institution in 1814 he was made professor of ancient literature in the university of Breslau and director of the philological seminary. Of his philological works, the most important is the "Dictionary of the Greek Language" (2 vols., 4th ed., Leipsic, 1831), still one of the most useful of Greek dictionaries.

PASSPORT, a document given by the authorized officer of a state, which permits a person or persons therein named to pass or travel either generally, or through a country named, or on certain routes, by land or water. Passports must have been used by all civilized governments to some extent and in some form; but in England and in the United States they have not been used within those countries, though their governments give them to those of their citizens who purpose to travel abroad. Each of the United States will give its passport to any of its citizens, and so will the government of the United States. The U. S. secretary of state is charged with the duty of issuing passports, and authorizing and regulating their issue by diplomatic or consular agents. Any one who issues a passport without authority, or who has authority and issues a passport to one not a citizen, is liable to punishment by fine and imprisonment. Passports are also given by collectors of ports to all vessels of the United States, and if any such vessel sails without a passport the master is liable to a fine of $200. One entitled to a passport may address a request to the office of the secretary of state, at Washington, and will be furnished with directions how to transmit the necessary statements and evidence; or he may, generally, learn all that is necessary from a collector of a port, or from a public notary. Every passport states the name, age, residence, and occupation of the holder, with a description of his person and appearance, which is intended to afford the means of identifying him. It is supposed to assure the holder of the support of his own government, and asks for him and entitles him to the protection of all governments or nations at peace with his own.—The rules and usages, in Europe, in respect to personal passports, differ almost indefinitely. In general, the bearer should take his passport to the minister or authorized agent of the country which he is about to visit, and have it signed by him; and on arriving at the outposts or frontier ports or cities of any foreign state on the continent of Europe, the passport must be exhibited, and so it must be at any principal town in the interior in which it is intended to remain for any considerable period. In many of the European states, a native citizen or subject cannot travel many miles in his own country without a passport. The whole system is productive of great annoyance and some expense to travellers. It has been kept up to afford the authorities means of surveillance over suspicious characters, and thereby to prevent conspiracies against the government, or provide the means of detecting them. The belief that passports have little efficacy for this purpose has been confirmed by recent experience; and the growing conviction that they are not so useful as they are inconvenient and oppressive, may have been the inducement for a recent change in the system in France, where it formerly flourished in full vigor, but where from the recent declaration of the emperor (Jan. 7, 1861) it is about to be relaxed in favor of English visitors to that country.

PASTA, Giuditta, an Italian singer of Jewish origin, born at Saronno, near Milan, in 1798. She received her first musical education from Bartolommeo Leotti, chapelmaster in the cathedral of Como. At the age of 15 she was admitted to the musical conservatory of Milan, where she was by no means a distinguished scholar, and in 1815 began her public career at the minor theatres in Leghorn, Parma, and Brescia. The next year, appearing at the Italiens in Paris, she failed to attract notice; she was equally unsuccessful in London, and decided upon returning to her native country to study further her profession. This she did in earnest; and when, in 1819 and 1820, she appeared in Venice and Milan, she was greeted with applause. Returning to Paris in 1821, and visiting Verona during the session of the European congress in 1822, she was remarkably successful. Her triumph in London was scarcely less brilliant, and for several years she continued to sing alternately in Paris and London. In 1827, some business difficulty having occurred between her and Rossini, then director of the Italian opera in Paris, she left France and accepted an engagement at Naples, where Pacini composed for her his opera of *Niobe*. Her dramatic powers however did not please the Neapolitans, though they were afterward fully appreciated at Bologna, Milan, Trieste, and Verona. It was at Milan that Bellini wrote for her *La sonnambula* and *Norma*. Pasta won her last triumphs at Vienna in 1832. Her voice, which had always been more remarkable for energetic than melodious qualities, was now impaired; and her last engagement on the Italian stage in Paris, in 1833 and 1834, was not on the whole successful, though she was much admired in Bellini's *Anna Bolena*, Rossini's *Otello*, and Zingarelli's *Romeo e Giulietta*. In 1836 she retired to her villa on the banks of the lake of Como, occasionally passing some time at Genoa and Milan, where she took pleasure in instructing pupils, among whom was Teresa Parodi. Her last engagement, by which she made $40,000, was with the opera in St. Petersburg in 1840.

PASTEL (Lat. *pastillus*), a colored crayon formed by the mixture of color with a colorless base. It is reduced by an application of gum water to the consistence of a paste (whence the name), which is cut into short sticks, and when dry is ready for use. Pastel painting is executed upon a paper manufactured for the purpose, the woolly surface of which assists in blending and retaining the tints. Sometimes vellum with the surface brought to a nap by friction is employed. The artist usually rubs in the tints with his finger, although for the finer kinds of work he also uses the stump or the point of the crayon. The art originated in Germany, but has been cultivated with most success in France by Greuze, Nattier, Girodet, and others.

PASTILLE. See PERFUME.

PATAGONIA, an extensive region of South America, occupying the S. extremity of the continent, bounded N. by the Argentine confederation, from which it is divided by the Rio Negro, E. by the Atlantic ocean, S. by the strait of Magellan, which separates it from Terra del Fuego, and W. by the Pacific as far as lat. 42° S., and thence for about 100 m. by Chili, the Chilian Andes forming the boundary line. It extends from lat. 38° 30′ to 53° S., and from long. 62° 55′ to 75° 40′ W.; extreme length 1,030 m., breadth 420 m.; area 315,000 sq. m.; pop. estimated at 120,000. The country comprehended within these limits is little known, and at present of but little importance. The whole of the coast has been examined by different navigators. There are several bays upon the Atlantic side, but they are not of much use to large vessels. On the N. part of the coast the tides rise about 30 feet, increasing to 50 feet toward the S. The Pacific coast is fronted by a chain of large islands which extend from the W. extremity of the strait of Magellan to lat. 42° S. The chief of these islands are Chiloe, the Chonos archipelago, Wellington, Queen Adelaide's archipelago, and Desolation island. They are all rocky and high, rising abruptly from the shores. The coasts next the Pacific are bare, being subject to frequent storms; but on the opposite side they are wooded, and in some places the timber is of large size. The general aspect of the Pacific coast is rugged and mountainous, broken by inlets and bays, and bordered by rocks and breakers.—Patagonia comprises two regions separated by the Andes, and entirely different both in climate and surface. E. Patagonia consists of a succession of shingly, horizontal plains, called pampas, which rise in terraces from the ocean to the foot of the Andes, where the last attains a height of about 3,000 feet above the level of the sea. The chief rivers in this tract have their source in the Andes, and generally run in a S. E. direction to the Atlantic. Some of them are deep and rapid, and have courses of considerable length, but only a few of the more northern have any effect in fertilizing the land upon their banks. The plains are dreary and sterile, and strewn with huge bowlders. In the S. there is a great deposit of tertiary strata, covered with a thick stratum of a white pumaceous substance containing a tenth part of marine infusoria, which extends for several hundred miles along the coast. This is covered with a bed of shingle 700 m. long, 200 m. broad, and 50 feet thick. The pebbles forming this bed are chiefly porphyry, and have become detached from the rocks of the Andes and water-worn since the deposition of the tertiary strata. Fresh water is exceedingly scarce, but there are numerous salt water ponds. To the N. of lat. 45° S. the country is not so completely barren as the S. portion; it becomes more undulating, and here and there are found good pastures and some trees. The climate is exceedingly cold in winter and hot in summer, and is remarkable for its dryness, no rain falling for about ¾ of the year.—W. Patagonia is wholly mountainous, and in every respect forms a strong contrast to the E. region. The mountains are barren and rugged near the coast, but the E. sides are well wooded. Opposite the island of Chiloe there are two active volcanoes. Heavy rains fall almost incessantly, accompanied by storms of wind, and there is so much bad weather that this portion of the country is nearly uninhabitable. The forests of the W. contain several species of beech and large ferns; and the vegetation of the N. part of E. Patagonia, near the Rio Negro, is the same as that of the Argentine republic. Where there is vegetation, particularly in the N. and W., different kinds of animals are found. Large herds of guanacos, wild cattle, the puma, the wolf, the fox, the opossum, the cavy, and the armadillo are met with. Fish and sea animals are abundant on the coasts; and sea fowl are exceedingly numerous. The condor, hawk, a species of ibis, and the South American ostrich are the principal land birds.—The Patagonians are a tall race, but by no means so large as they were described by early travellers. Their bodies are bulky, but their limbs are not large in proportion. Mr. Bourne, mate of an American vessel, who was in captivity among them in 1849–'50, describes them as about 6½ feet in height, while some few are still higher. Their shoulders are broad, and their chests well developed, their heads and features large, but their hands and feet comparatively small. They are naturally indolent, but when sufficiently aroused exhibit great strength. Their color is a reddish brown, and their hair black, coarse, and lank. They have large mouths with thick lips, but good teeth. They color their faces and bodies with white, blue, or red paint. The hair, tied above their temples with a fillet of twisted sinews, is the only covering for the head; and they wear a large mantle, made of skins sewed together, hanging loosely from their shoulders to their ankles, which adds greatly to their apparently gigantic size. For their feet they make boots out of the skins of horses' hind legs. The stature, dress, and appearance of the women so much resemble those of the men, that were it not for the hair, which they plait in two tails, it would be difficult for a stranger to distinguish them. They are generally good-natured, but when excited are passionate and reckless. They appear to possess nothing like towns, and to lead a wandering and unsettled life. Their huts are formed of a few sticks covered with the skins of animals. Their arms consist of a long lance, a bow and arrows, a knife if it can be procured, and balls made fast to the ends of a long leather thong, which they throw with a rotary motion and use for entangling the legs of animals. They are all expert horsemen. There are several distinct nations in different parts of the country, and those who inhabit the W. coast are of much lower stature than the others. Their chief subsistence consists of the flesh of horses, guanacos, and such other animals as they can capture. They are filthy in their habits, exceedingly vain, and great liars.—Magalhaens is generally supposed to have been the original discoverer of the S. coast of Patagonia. Other navigators, whose names deserve to be mentioned as connected with the discoveries upon its coasts and in the seas adjoining, are Drake, Le Maire, Davies, Cavendish, Hawkins, Cook, Sarmiento, Narborough, Cordova, Byron, Willis, Carteret, Bougainville, Weddell, King, Stokes, and Fitzroy. Many attempts have been made to form settlements upon the coasts and on the neighboring islands, but until lately none of them met with any success. The government of Chili claim the W. part of Patagonia, and the Argentine republic the E. side. The Chilenos have lately formed a few small establishments, extending as far as the E. entrance of the straits of Magellan, and are making efforts to explore the interior.

PATAPSCO, a river which rises in Carroll co., Md., flows southward and then south-easterly between Baltimore and Anne Arundel counties, and passing Baltimore opens into a broad estuary which enters Chesapeake bay 14 m. below the city. Its total length is about 80 m., and it affords valuable water power. It is navigable for large vessels to Baltimore.

PATENTS, Law of. Nothing like the law of patents was known to the ancients, or is now known out of Europe and America. Even there it is comparatively recent. In England it is but little more than two centuries old. In France, the earliest law in favor of new inventions was passed in 1790; and in the United States the system of patent law rests, not on common law, or usage or any reference to natural right, but only upon the statute of 1793 and those which have been made subsequently in amendment or alteration of that, the latest of which was approved March 2, 1861. Indeed, there seems to be now no recognition by courts of any abstract right in an inventor to the exclusive use of his own invention. The theory of the patent law is rather that of contract; the inventor bargains with the public that he will tell them how to do some new work, or some old work in a new way, which shall be useful to them; and they bargain with him that whoever makes use of it for a certain time shall pay him therefor. The purpose of the patent law is to encourage invention for the public good, by the stimulus of the large rewards which a monopoly of any useful instrument must yield. As all our patent laws rest upon express statute law, it might seem as if no consideration of its theory, purpose, or foundation could affect the rights or obligations or remedies of any persons. It may however be very important as bearing upon the question of construction. Patent cases abound with questions, sometimes of very great importance, which may be decided either way in conformity with unquestionable principles and arguments of great weight; and those will seem to be the better principles or the stronger arguments which concur with the presumption adopted, either that a patentee is a monopolist, who owes all his rights to exceptional law, and must be jealously watched, or as a public benefactor, who is to be kindly and tenderly treated. Formerly, in England, the first of these suppositions seemed to be generally made, and a patentee was treated with extreme severity; now, he is there treated more liberally. In the United States, also, whatever may have been the language of the courts in some cases, a patent was seldom permitted to stand, if any ingenuity could detect a flaw. In consequence of the severity of some of the rules of the courts, various statutory provisions were made, as for disclaimer, surrender and renewal, previous use, &c., of all which we shall speak presently. Now, however, we would observe, that while the courts generally adopt a course far more favorable than formerly to the patentee, there scarcely seems as yet a universal recognition of what should undoubtedly be regarded as the true principle, namely, that both parties should be treated rationally and justly and impartially.—In no other country are inventions and patents for inventions so numerous as in this; and our statutes provide liberally and wisely for all those things which may tend to give encouragement and assistance to useful inventors. The patent office is a branch of the interior department; it has a commissioner with a large staff, and three examiners in chief, all well paid, among whom the duties of the office are skilfully divided. A library of such works of science or art as might be useful, is kept in the office; and there is a careful and well devised arrangement of all the models gathered since the destruction of the former patent building on Dec. 15, 1836. To secure the impartiality of the persons employed in the office, they are all prohibited from having or receiving any interest in any patent whatever, other than what may come to them by inheritance. I. *Who may have letters patent?* The statute says: "Any citizen or citizens, alien or aliens having resided one year in the United States, and taken the oath of his or their intention to become a citizen or citizens." They must be the inventors or discoverers of the thing, and not merely introducers of it into this country. If the applicant for an American patent has already, as the inventor thereof, a patent for the same thing in a foreign country, his patent when taken out here will expire as soon as it would if the date of the American patent were the same as that of the previous foreign patent; in other words, it is taken out for 14 years from the date of the foreign patent. Nor can a patent issue in this country for an article patented abroad, if that article has been introduced into common and public use here previous to the application for the patent. It may be remarked, that it is a very common thing for an American inventor to take out a patent in foreign countries, particularly in England and France. If the inventor is dead, the patent may issue to his legal representatives; if he has assigned it, it may issue to his assignees; but none are his assignees but they who receive the whole of his interest. If he reserves any part it cannot be issued jointly to him and his assignees; but if he has more than one assignee, it may issue to all the assignees jointly. II. *What may be the subject of patent?* In the language of the statute, "any new and useful art, machine, manufacture, or composition of matter, or any new and useful improvement on any art, machine, manufacture, or composition of matter." There is scarcely a word in this description that has not been criticized and discussed again and again. 1. It must be new. Here some distinction appears to be made in regard to a previous knowledge when the thing is foreign and when it is domestic. If what is claimed as new was distinctly known to some person abroad, but was never patented there, nor published, nor distinctly described in any work, it is new enough to be patented here; but if it was previously distinctly known by any one at home, it is not new in the sense of the patent law, although he who knew it may never have published it in any way. It must be remembered, however, as a very important rule, that a mere previous conjecture, supposition, or conception is not enough to prevent or defeat a patent. It must have been definitely known and reduced to form, or distinctly manifested in some way. Mere thinking about it, or talking about it, is not enough to prevent a subsequent inventor from getting out a patent. The question is: Was it previously described in writing, with drawings or models if they were necessary? There is some disposition to adopt a rule which is certainly reasonable, and applicable without much difficulty, viz.: that a patent shall not be defeated because the thing was previously invented, unless the previous inventor had done enough to entitle himself to a patent; and this would imply that he had reduced the invention so distinctly into form, that a mechanic of reasonable skill might, from his description and without further invention, make the thing patented. Again, it is no defeasance of a patent, that some one, claiming to be a previous inventor, had communicated to the patentee suggestions or plans which were in fact the essential features of the thing patented, and about which the rest had grown, provided the patentee invented and first applied those needed accessories and first constructed the whole thing. It is of no consequence whether the thing was discovered by accident, and at once, or was the result of long, careful, and assiduous labor. Nor is it of moment whether the patentee discovered the whole thing and all its parts himself; for if some parts are old and well known, and others suggested by different individuals, until perhaps there is no one element newly discovered, yet if the whole, in its present form, construction, and action, is new, and is the invention of the patentee, that is quite sufficient. The patent would not be given, or if given it would be void, if the applicant, before his application, has himself abandoned the thing to the public, which will be presumed if "it has been, with his consent and allowance, more than two years in public use or on sale." But his own use of the thing previously will not prevent him from having a valid patent. The statute says that the thing must not be previously "known or used by others;" but it is held that this plural word has also a singular meaning, and if it was known or used by one other, the patent is invalid. 2. In regard to the word "useful," it is perhaps enough to say, that any degree of utility is sufficient to satisfy the statute; and we suppose that very few patents are withheld merely because of the inutility of the thing to be patented, if there be no other objection. 3. It has been questioned what the word "manufacture" covers. In England, what is called the statute of monopolies (21 James I., ch. 3), which was intended and has operated to prevent the ancient oppressive monopolies, permits letters patent (under which monopolies had formerly been granted) still to issue for the "working or making of any new manufactures within this realm." It is under this statute that all letters patent are now issued in England; and to enable them to cover all suitable cases, the word manufactures is construed to mean every thing in the making or preparing of which man makes any use of his hand, that is, of physical power, in any way whatever. The meaning of the word by our adjudication is not quite so broad, because our statute contains other words. There is indeed scarcely any thing which man can do, or invent, which will not come under some of these words; but it is sometimes necessary to determine to which class the thing patented belongs. 4. A "machine" must not be a mere function, or effect, or operation, but it must be a function clothed and embodied in mechanism intended for and operative of a certain effect. If this effect is new, the mechanism which produces it may be old or new. That is, the inventor may have a patent for new mechanism by which he produces a new effect, or for mechanism no part of which is new, if the whole machine, as he constructs it, produces an effect unknown before. It is to be remembered, however, that the mere using of an old machine to do a thing which it had not been used for before, but like what it had been used for, is not the proper subject of a patent. Thus, to use an illustration of this rule given in one case, a man may not observe that a certain mill grinds corn and beans very well, and then take out a patent for it as a coffee mill because he was the first that ever thought to put that mill to that use. But he may have a patent for his coffee mill, although every thing in it has been used before, and although something like it has been used for some grinding, if the same thing has not been applied to do work of the same nature. In stating, and in endeavoring to illustrate such a rule as this, we are reminded of a phrase Judge Story used often to apply to the patent law. He called it "the metaphysics of the law." Many of its distinctions are slight and almost evanescent, and many of its principles scarcely capable of distinct definition; and yet these distinctions and principles are of very great practical importance. 5. Thus, where the patent is not for any new machine, but for "an improvement" in an old machine, which is a very frequent subject of patents, the question, whether it is a lawful improvement or a mere infringement, is sometimes one of the utmost difficulty. We must content ourselves with saying, that if this improvement consists in producing an old effect in a new way, the practical questions are: 1st. Is the effect produced in a way which is actually and substantially different from the old way? for otherwise it is a mere repetition, and may be a mere device to avoid the old patent. 2d. If the same thing be done in a new way, is it done in a better way? because otherwise it is no improvement. Here, as was said of the utility of an invention, the improvement need not be very great; and in general, if the thing be done really in a new way, a patent will usually be granted and protected, unless it seem to be a mere variation or change, of no value excepting because it may invalidate a former patent. For scarcely any thing was ever invented, or perhaps ever will be, that does not suggest at once a multitude of possibilities for doing the same kind of thing; and it is therefore very rare for any new discovery of importance, whether scientific or practical, not to be followed up by a host of those who may not perhaps be called imitators, but who certainly would never have done what they did, had not the way been opened and indicated by the earlier discovery. The difference between the old and the new may to all appearance be very slight, and yet be of great importance. This may be well illustrated by the process of water-proofing cloths, as it was called. Many years ago some one found that cloths immersed in a solution of soap and alum were made water-proof. Then a man took out a patent for immersing cloths first in a solution of alum (with an ingredient or two added), and afterward in a solution of soap; and this patent was sustained, because it was proved that the immersion into the separate solutions successively made the cloth much more completely and permanently water-proof. 6. Another rule, of very frequent application, is that no mere principle can be the subject of a patent; nor can any mere effect; nor can any property of matter or mere quality or power or activity of nature. All this constitutes but one rule; and this might perhaps be expressed by saying that nothing in the abstract can be the subject of a patent. Any of these things, however, in the concrete, can be patented; by this is meant any principle or property which is fixed and embodied in certain mechanism, which then, by means of this principle or power, produces a certain effect. But then it is not so much the principle or power in the mechanism which is patented, but the whole together; nor is the effect alone patented, but the effect when produced by these means in this way. The reasons of this rule are many. One is the almost inevitable indistinctness which would attach to such a patent. Another is, that were the rule otherwise, things might be appropriated and monopolized, which are in themselves universal and the common property of all men. If a mere principle is discovered, even if it be of the utmost importance, such for example as the principle of gravitation, this takes its place at once in science. The discoverer cannot be repaid excepting by the homage rendered to one who has laid all mankind under obligation, by giving to them new truth. But either he or any other man may at once devise and put in operation means by which a new scientific truth or a newly discovered principle is made to operate some practical benefit. Then, as has been said, the principle has become a process. Then this principle with this mechanism as its instrument, and a certain result as its effect, form one legal entity, and that is the subject of a patent. But this patent gives no exclusive right to use this principle or this property, or to produce this effect. Therefore any one who finds out another useful application of the principle or property, or other means by which it may produce this same effect, is also an inventor or discoverer of a new thing, for which he may have his patent. Hence arises what may be considered as the third reason for the rule above stated; it is, that but for it the extent of a patent might be enormous and intolerable. The owner of it might say: "The whole of this principle or power is mine, and that effect is mine however produced." But as the law stands, the principle or property is his only so far as he has fastened it to his own machinery; and the effect is his only so far as he reaches it through instruments of his own invention. No man can acquire exclusive property in the electric fluid, nor can he in any one of its properties or powers. So no man can become the owner of the sun's light, nor of that actinic power by which pictures are painted or impressed. But he may devise any way of working with electricity, and that way shall be his; and so he may discover any way of making pictures or representations by light, and that way also shall belong to the inventor. And then any other person is at liberty to discover some other way of using either of these forces or qualities of nature. But one thing always remains; and that is, the watchfulness of the law to guard an honest patentee from invasion of his rights by a mere colorable pretext of a variation in the method discovered by him of using a certain power in a certain way for a certain end. No better rule can be given than that each patent holds all that belongs to its substance; and any thing is an infringement which does not differ from it materially and substantially. 7. The last phrase used in designating the subject matters of patent, is "composition of matter." This will require but little discussion. It is usually applied to medicines, and less frequently to compositions used in the arts, as for example alloys for the bearings of axles. Here it is obvious that the test question must be, not whether the materials are new, but whether the combination is new. Hence an applicant for a patent for a new composition of matter may use various ingredients, and declare that one as well as the other will answer his purpose, provided that the combination, whatever be used, has in it the element of unity, so far that it is one in its purpose and its effect. 8. By a more recent act (1842) another class of objects may be the subject of a patent, viz.: designs for manufactures of any kind. Some of these might seem to be more properly within the scope of the law of copyright. But for any design, or pattern, or drawing, or print, or picture, which is intended not to have value by itself, but to be used in the manufacture of something else, or to be fastened in any way to some article of manufacture, and be sold with it, the inventor may have letters patent. III. *How Letters Patent may be obtained.* 1. The first step is an application. This must be in writing, addressed to the commissioner of patents, and signed by the original inventor. Even if he have assigned the invention, and the patent is to be made out in the name of the assignee, the application must be signed by the inventor. If he be dead, it must be signed by his executor or administrator. There is no special form required, but it must state distinctly, although generally, what he considers the invention or discovery for which he asks a patent; but no mere mistake in the application will vitiate the patent. By a rule of the patent office, no patent issues for more than one machine, although two or more may be used jointly; and in that case each must be made the subject of a separate patent, although the petitioner may express his desire for both in one application; but it would be better in all respects to treat each machine, from the beginning, as a separate thing, if it be so in fact. With the application he sends to the commissioner a specification of his claim. There must be drawings attached and referred to if these are necessary to understand the specification, and these should be in duplicate, that one copy may be retained in the patent office. Also a model is required wherever that is the best way of illustrating the specification, and a working model is preferable; but no model should be more than one foot in length or height, unless by permission of the commissioner, which is never given but for special reasons. By the 11th section of the recent statute, letters patent may be obtained for any new and original design for a manufacture, or for a bust or bass-relief, or composition in alto or basso-rilievo, or impression or ornament to be placed on any article of manufacture, or any new and useful pattern or print or picture to be fixed on any article of manufacture, or any new and original shape or configuration of any article of manufacture. The exact force and meaning of these phrases will not be known until they are determined by adjudication. It may be added, that the same section provides that the patent may issue on any of these things for 3½ years, 7 years, or 14 years, as the applicant may choose; the fee in each case being respectively $10, $15, or $30, and to all foreigners $300. Money should be deposited with some assistant treasurer, and his certificate taken in duplicate, one copy to be sent on; or the money may be sent through the mail. The applications received are examined in the order in which they come, unless some one is taken up out of its turn for special reasons. If the claim be allowed, a patent will issue and be sent according to the direction of the patentee. If it be rejected, the claimants will always be furnished by the commissioner with the reasons for rejection, and with such references to former patents, or other similar means of information, as will enable the claimant to judge of the sufficiency of the grounds of rejection and of the probability of a successful appeal. 2. It sometimes happens that two or more persons claim each to be the first inventor of the same thing. Then the commissioner declares a case of "interference" to exist, and after due notice to the parties, they are heard in support of their several claims. This may happen although one of the claimants has received a patent at some time before; for the commissioner, if he comes to the conclusion that the second claimant has a better right, or an equal right, will give him also a patent, and leave the two to determine by legal measures which is valid. 3. In all the questions which thus come before the commissioner, or the examiners, on the question of granting a patent, or before any court subsequently in a suit for infringement of the patent, the specification is of the utmost importance. Upon its clearness, its accuracy, its exactness in defining its claim and in claiming what should be claimed and nothing more, a very large proportion of the cases tried depend. The points to be observed are those indicated in the 6th section of the statute of 1836. They are in substance: 1st, that the description shall be so full, clear, and exact, without prolixity, as to enable any person skilled in the art or science to which the thing belongs or with which it is connected, to make and use the same; 2d, that the principle shall be fully explained, "and the several modes in which he has contemplated the application of that principle or character by which it may be distinguished from other inventions;" and 3d, he must specify and point out the part, the improvement, or the combination which he claims as his own. This last requirement is so important, that it has given the name of "specification" to the whole description. All this may seem, to those who have not tried it, very easy; but nothing is more difficult. Mistakes of importance are not unfrequently made by those who are trained to this work, and who make it their special business; and it can very seldom, if ever, be safe for any claimant to draw his own specification, unless he has large experience in work of this kind. Mistakes are not so fatal now as they were formerly, because recent legislation has interposed, wisely as well as kindly, to assist the patentee. If a patent is void by reason of a defective specification, or because the patentee claimed as his own invention more than he had a right to claim as new, he may surrender his patent to the commissioner, and file with him a new and corrected specification, and the commissioner may thereupon issue to him a new patent. Or, by a still later provision, the patentee may make a disclaimer in writing of such parts of the thing patented as he shall not wish to claim; and this disclaimer, being duly received and recorded, shall have the same effect as if it had been originally a part of such specification. Even without such surrender or disclaimer, a patent may still be sustained by the court, for any material and distinguishable part for which the claim was valid, although there are other parts of the claim to which the patentee is not entitled; but he can recover no costs for the infringement of such a patent without surrender or disclaimer. 4. There is a very wise provision to meet the frequent case where an inventor wishes to secure his right, but is not ready to present a full and complete specification, and needs time for experimenting, or other purposes. He may file a *caveat*, which will be placed in the secret archives of the patent office; and if there be any application within a year for any thing which appears to interfere with his claim, he shall have notice and may appear and prove priority; and by paying a second caveat fee ($20), he may renew it for another year, and so on successively. It is to be noticed, however, that a caveat cannot be filed by an alien, unless he has resided in the United States one year, and has made oath of his intention to become a citizen, according to law. Even where caveats are not taken out, all pending applications are regarded as so far confidential, that, until after a patent is issued, no information will be given to any one but the claimant respecting the existence of any application, or any questions which may have arisen in relation to it. 5. To guard against deception of the public as to what inventions are protected by patent, any person who shall, in any way whatever, put any word or remark upon a thing not patented which shall indicate that it is the subject of a patent, or put upon it the name of any patentee without his consent, or, if it be patented, fail to stamp or engrave on the article the fact and date of the patent, is liable to a heavy penalty. 6. The terms of patents for designs may be extended for 7 years from their expiration. Formerly the terms of all patents might be extended under certain restrictions, and the rules and provisions on this subject were minute and complicated. It was thought, however, that they did not suffice to prevent mischief from improper extensions, or from favoritism or mistake in discriminating between applicants for extension, and by the patent law of March, 1861, the whole law of extension, with the above named exception, was abolished as to patents thereafter granted; but the provisions of the preceding law as to extension would seem to remain in force as to all patents previously granted. IV. *Rights and Remedies of Patentees.* So long as the patent remains in force, it gives to the patentee an exclusive right to "make, use, and sell" the thing patented. Whoever infringes on this right is liable in damages, and the infringement may be stopped by injunction. We will consider first what is an infringement of a patent, and then what are the remedies for an infringement. 1. The statute contains no definition; but it has been well said, that an infringement exists when a copy is made agreeing with the principle and action laid down in the specification. Infringements therefore may be of as many kinds as patents are. Perhaps it is impossible to give rules and definitions which shall meet all this variety of cases and be of much use in determining the question of infringement. It is certain, however, that a patentee is seldom permitted to call that an infringement which imitates nothing that is directly and explicitly stated in the specification. For if the patentee did not know this or have it in his mind, he cannot claim it as his; and if he knew it and did not state it, whether through negligence or design, he has failed to lay the foundation of his exclusive right, because he has not placed on record a full, clear, and explicit description of his invention. Perhaps the difficulty attending this law of infringement, and the principles invoked to dispose of it, may be well illustrated by reference to a recent English case which has gone through the courts there and been the subject of much discussion. One Heath invented and patented an important improvement in making steel. This invention consisted in putting into a crucible with pieces of iron carburet of manganese, and exposing the mixture to intense heat. But carburet of manganese is a very expensive chemical product; and one Unwin discovered that by putting into the crucible with the iron oxide of manganese and coal tar, the intense heat to which they were exposed made a carburet of manganese in the crucible, which then operated on the iron in the same way as if this compound had been put there at the beginning; and as oxide of manganese and coal tar are very cheap, Unwin's way was likely to supersede Heath's, who brought an action for damages. The case was tried before Mr. Justice Cresswell, who ruled that there was no infringement. It was then argued before 6 judges in the exchequer chamber, 2 of whom agreed with Cresswell, and the other 4 held that there was an infringement. The case was then taken to the house of lords, and the judges of England were requested to give their opinion to the lords; and after argument, 7 judges gave their opinion that there was an infringement, and 4 judges gave theirs that there was no infringement. At length the question was finally decided by the lords, that there was no infringement; thus overruling the majorities of two assemblages of the judges of England. The principal reason for holding that there was an infringement was, that the thing patented was improving steel by mixing carburet of manganese in the crucible with it, and it was wholly immaterial whether this compound was made out of or in the crucible; while the principal reason for holding that there was no infringement was, that the thing patented was the putting a certain compound into the crucible with iron, and thereby producing the effect, whereas Unwin put wholly different materials into the crucible, and then, by means of a double electric affinity and chemical action, they produced their effect. 2. As to infringement by the sale of the thing patented, it must be a sale of the whole thing, and not of the different parts or materials out of which it may be made. Yet no evasion of a patent right would be permitted, merely by selling a part at one time, and to one person, and other parts to others, with the intent that they should be put together and so make the whole machine. 3. A curious question has arisen as to the interference of local rights under a patent. Thus, a man has a right for the county of Hamilton to make and sell certain patent bedsteads; another man has a similar right for the adjoining county of Dearborn. The first man sells a large quantity to a purchaser, who takes them into Dearborn and undersells the person having the right for that county. It seems now to be determined that this is not an infringement or unlawful interference; and the supreme court of the United States have gone even further than this, and have decided that any one who has an exclusive right to a patented machine within a certain district, cannot use that machine out of that district, but that he may sell anywhere the products made under the patent within that district. 4. Interesting questions have arisen as to the right of repair. If one buys a patented machine, and it wears out, he cannot make another under pretence of repairing that which he bought; but he may prolong its existence and utility by mere repair as long as he can. If he repairs this part to-day, and that to-morrow, and in every repair makes some renewal, until at last no part of the original machine is left, we doubt whether the law would interfere, if each repair had been made at the time in good faith, as repair and not as renewal. 5. It remains to treat only of the remedy in case of infringement. The statute of 1836 provides that damages may be recovered by "an action on the case;" which right would exist equally at common law. But this remedy would often be wholly inadequate, were it not for the further and more effectual remedy provided by the principle of equitable jurisprudence, that wherever a legal right exists, and this right is invaded or violated, and the damages recoverable are an insufficient remedy, courts of equity will grant an injunction against the offender and so prevent a repetition of the offence. But this great remedy will not be granted unless the court can see that it is necessary to prevent further violation of right, and vexatious and insufficient litigation. And if this injunction or prohibition against a repetition of the offence be disregarded, the offender will be punished by imprisonment, or such other penalty as will, in the judgment of the court, compel obedience. Generally, an injunction will not be granted until the plaintiff's rights and the defendant's wrong doing have been established in an action at law. But when the infringement is certain, a court of equity will proceed at once; and not unfrequently, on petition of the patentee, they direct a trial at law, and order the defendant to keep an exact account of all that he makes or sells in supposed infringement of the patent, to be rendered if the trial results in establishing the infringement.—The commissioner of patents makes a yearly report to the secretary of the interior, which, with its accompanying documents, is published at government expense; these constitute in some degree the records of the office. The whole number of patents granted by the U. S. government up to March 18, 1861, was 31,670. In the years from 1840 to 1849 the average of applications for patents was 1,000; the average of patents granted was 550. For the succeeding 7 years the average of applications was 3,800, and the average of patents granted was 1,750. In 1858 the number of patents granted was 3,710; in 1859, 4,538; and in 1860, 4,819. During 9 years of its administration the expenditures of the patent office have been greater than the receipts; but at all other times the receipts were considerably in excess of expenditures. There is now (March, 1861) in the treasury of the patent office $89,000.—The commissioners of patents in Great Britain have printed in several hundred 4to. volumes (1853–'8) the specifications of all the patents granted in that country up to 1852, amounting to about 13,000, with lithographed plates in separate folio volumes.

PATERCULUS, Caius Velleius, a Roman historian, born about 19 B. C. He was descended from an ancient Campanian family. His father was prefect of cavalry, and the son, early entering military life, attended C. Cæsar, the grandson of Augustus, in his eastern expedition in A. D. 2, and subsequently served under Tiberius in Germany, Pannonia, and Dalmatia. In 6 he became quæstor, had a share in the triumphal procession of the emperor in 12, and was elected prætor in 14. He had early gained the good will of Tiberius, and of his favorite Sejanus, and it has been conjectured that he was executed in 31 with the latter and his friends, although nothing certain is known of his death. His reputation rests upon his Roman history, which appears to have been written in A. D. 30, and goes under the title of *C. Velleii Paterculi Historiæ Romanæ, ad M. Vinicium Cos, Libri II.* The manuscript was discovered in the monastery of Murbach in Alsace by Beatus Rhenanus, who printed it at Basel in 1520.

PATERSON, the capital of Passaic co., N. J., on the Passaic river, near the falls, and on the Morris canal and New York and Erie railroad, 17 m. N. W. from New York; pop. in 1860, 19,618. It is a well built city with paved streets, generally wide and straight and lighted with gas, and contains a large number of handsome private residences. The falls supply power to many factories, several of which occupy extensive stone buildings. There are 8 large cotton mills, having an aggregate capital of $595,000, and producing annually to the value of $752,961, principally cotton yarn. Of these, the Paterson manufacturing company and the Phœnix manufacturing company make large quantities of cotton duck, the former to the annual value of $115,000. Paterson is specially noted for its extensive machine shops and steam-engine manufactories, and is stated to make at least half the locomotives constructed in the United States. The Rogers locomotive and machine works have a capital of $300,000; during the year 1860 they employed an average of 720 hands at an expense of $24,000 a month, and turned out, beside a large quantity of cotton and other machinery, 90 locomotives; total production, $765,000. The establishment of Danforth, Cooke, and co., capital $300,000, employed 540 hands and produced to the value of $583,000, including 36 locomotives. There are 7 other machine shops of some extent, with an aggregate capital of $190,000 and an annual production of $244,812, and a manufactory of stationary steam engines, capital $40,000, producing $95,000. The paper mill of H. V. Butler and co. occupies a fine building, and, with a capital of $200,000, manufactures to the value of $289,000. Among others are 4 silk manufactories, aggregate capital $153,000, producing $846,000; 1 flax and hemp, capital $200,000, producing $140,000; a printing, dyeing, and bleaching establishment, capital $200,000, producing $180,000; and a wick and twine factory, capital $40,000, producing $75,600. Beside the county offices, there are an academy, a bank, 2 newspaper offices, a mechanics' and a philosophical society, and 16 churches, viz.: 2 Baptist, 1 colored Congregational, 1 Episcopal, 1 Independent, 4 Methodist, 2 Presbyterian, 3 Reformed Dutch, and 2 Roman Catholic. The town was founded in 1791 by a manufacturing company with a capital of $1,000,000.

PATERSON, William, founder of the bank of England, and of the Scottish colony of Darien, born according to tradition in Skipmyre, Tinwald parish, Dumfriesshire, in the spring of 1665, died in Jan. 1719. He was originally destined for the Presbyterian ministry, and is said to have been among the Covenanters persecuted by Charles II. To escape from these persecutions he went to London in the capacity of a merchant, and also visited America, where he acquired from the buccaneers much information in regard to the Spanish main, of which he subsequently made great use in connection with the Darien expedition. It is a question whether he was criminally concerned in the violent courses of these marauders, but the probabilities are that he was not. In 1692 he was a merchant in London, as is evident from a lease authorizing him and two others to construct the Hampstead water works. About this time he made proposals in regard to founding a bank of England, and a tract entitled "A Brief Account of the intended Bank of England," is supposed to have been written by him. He was one of the first directors of the institution, but for some cause resigned. He had long before conceived the project of founding "a free commonwealth in Darien," and after several unsuccessful efforts to have his scheme adopted by England and by other states, it was finally sanctioned by a Scottish act of parliament in 1695 constituting the Darien company. (See Darien, Colony of.) After the failure of the expedition, which would probably have been successful if his advice had been followed, he returned to England and devised a new plan for the colony; but the unexpected death of King William, over whom he had great influence, destroyed all possibility of reviving the project. He was an able advocate of the union of England and Scotland, and when the treaty to that effect was passed, an indemnity was recommended to be given him on account of the losses he had suffered in the Darien expedition, and of his "carrying on other matters of a public nature, much to his country's service." But it was not till the reign of George I., and after a long struggle with the government for the settlement of his claims, that it was paid. Paterson was in 1708 a member of parliament for Dumfriesshire. The last years of his life were spent in Westminster. He was an early and zealous advocate of the principles of free trade, was a decided opponent of the schemes of John Law, and in all matters of trade and finance his ideas seem to have been far beyond the times in which he lived. (See Bannister's "William Paterson, the Merchant, Statesman, and Founder of the Bank of England, his Life and Trials," Edinburgh, 1858.) His works, which are numerous, have been lately collected under the title of "The Writings of William Paterson, with a Biographical Introduction" (2 vols. 8vo., 1858).

PATKUL, Johann Reinhold, a Livonian nobleman, born in a prison at Stockholm about 1660, executed at Kazimierz, near Posen, Oct. 10, 1707. Livonia being then a province of Sweden, he first served as a captain in the Swedish army. In 1689 he was one of a deputation of noblemen sent to Charles XI. to remonstrate against the encroachments of the royal officers upon the rights and privileges of Livonia; and although among the youngest, he was chosen spokesman, and addressed the king with particular energy. Three years later, in the capacity of a deputy from his fellow nobles, he remonstrated strongly with the Swedish governor at Riga, and addressed an eloquent letter to the king. Having participated in other patriotic manifestations, Patkul, in connection with the marshal and members of the Livonian diet, was summoned to Stockholm. Procuring a safe-conduct, he obeyed the summons, but soon judged it necessary to flee to Courland; and a few weeks after his escape he was condemned to be beheaded as a rebel, his property was confiscated, and his writings were burned by the executioner. Being no longer safe in Courland, he retired to the canton of Vaud, Switzerland, where he engaged in scientific pursuits, and afterward visited France. In 1698, after the accession of Charles XII., he sued for pardon; but his petition being rejected, he entered the service of the elector Augustus II. of Saxony, king of Poland, who appointed him one of his privy council. He participated actively in the coalition between his new master, the king of Denmark, and the czar of Russia against Charles XII., and at different times endeavored to rouse Livonia against the Swedish rule. Dissatisfied with the overbearing manners of Flemming, the principal minister of Augustus II., and having moreover, during a mission to Russia, won the favor of Peter the Great, he accepted from the czar the rank of general and the office of Russian ambassador to Dresden. This conduct roused the displeasure of Augustus II., who, notwithstanding Patkul's official character and the risk of endangering his friendly intercourse with the czar, caused him to be arrested in 1705. When afterward Augustus, defeated by Charles XII., was obliged to abdicate his Polish throne, one of the conditions of peace imposed upon him was the surrender of Patkul. Augustus gave secret orders that his prisoner should be suffered to escape, but they were not obeyed. By Charles's command, Patkul was taken to the convent of Kazimierz and condemned to death by a court martial. He was first broken on the wheel, and then, while still living, carried to the scaffold, where he was beheaded. His corpse was then quartered and put on the wheel again. When Augustus II. was replaced on the throne of Poland, he caused the remains of Patkul to be collected and buried at Warsaw.

PATMORE, Coventry, an English poet, born in Woodford, Essex, July 23, 1823. He is the son of P. G. Patmore, a man of much literary industry in the early part of the 19th century, and commenced his career by the publication of a volume of poems which attracted little notice. It was succeeded in 1853 by "Tamerton Church Tower and other Poems," and in 1856 by his most popular poem, "The Angel in the House," in two parts, the first entitled "The Betrothal" and the second "The Espousals." His last work, "Faithful for Ever" (London, 1860), a sort of pre-Raphaelite attempt to give a poetic interest to the commonplace incidents of life, has been severely criticized by the leading literary periodicals of Great Britain, but has met with a warm eulogist in Mr. Ruskin. Mr. Patmore is also a contributor to the "Edinburgh Review." Since 1846 he has been one of the assistant librarians of the British museum.

PATMOS, or as it is now called **Patmo**, an island of the group called the Sporades in the Grecian archipelago, 20 m. S. of the W. extremity of Samos, and about the same distance W. of the coast of Asia Minor. It consists of an irregular mass of barren rock 28 m. in circumference, and in the time of the Roman emperors was used as a place of banishment. It was to this island that St. John the apostle was exiled by the emperor Domitian, A. D. 95; and here, according to universal tradition, he wrote the Apocalypse, and perhaps his Gospel also. On the side of a hill a cavern is pointed out by the Greek monks, who have a monastery in the vicinity, as the exact spot where the evangelist received the revelation, and through some fissures in the roof he is said to have heard the "voice from heaven like the sound of a trumpet." The monastery, built by the Byzantine emperors in the 12th century, is under the patronage of

"St. John the Divine," and inhabited by about 50 monks, subject to the patriarch of Constantinople. On the E. side of the island there is a small village and a good port. The island is subject to the Turks, but the inhabitants, 4,000 in number, are all Greeks. They subsist chiefly by agricultural labor on the mainland or the more fertile islands, migrating for the purpose every summer.

PATNA, a district of British India, in the lieutenant-governorship of Bengal, bounded by the districts of Sarun, Tirhoot, Monghyr, Shahabad, and Bahar, extending from lat. 25° 8′ to 25° 38′ N., and long. 84° 45′ to 86° 10′ E.; area, 1,828 sq. m.; pop. 1,200,000. Beside the capital, of the same name, the chief towns are Dinapore, a large military station, and Phatuka. The Ganges flows along its N. frontier, and the river Sone forms the W. and N. W. boundary and is navigable for a considerable distance. There are many smaller streams, and during the rainy season the province is intersected by water courses in every direction. It is fertile and highly cultivated. The climate is very hot in summer. The growth of the white poppy, from which opium is made, is a monopoly rented to the Patna opium company by the government. About 6,500,000 lbs. of poppy juice are annually manufactured, yielding a revenue of £3,500,000. The East India railway passes through the province. Patna was included under the grant of Bengal, Bahar, and Orissa, made by Shah Alum to the English in 1765. It was the scene of some of the most memorable events in the great mutiny of 1857, every part of the district except the capital having been for a long time in the hands of the insurgents.—PATNA, the capital of the above described district and of the province of Bahar, is situated on the right bank of the Ganges, 300 m. N.W. from Calcutta; pop. 284,132. The city proper, or fort, is of rectangular form, surrounded by a wall which extends about 1½ m. along the bank of the river, and ¾ m. inland. The suburbs are very extensive, and stretch about 7½ m. along the Ganges. The principal thoroughfare, parallel to the river, is wide, though neither straight nor regular; and the other streets and lanes are narrow and crooked. Some of the houses are built of brick, and have flat roofs and balconies; but many of them are made of mud, and covered with tiles and thatch. There are several Mohammedan mosques, but they are regarded with little reverence, and most of them are now used as warehouses. There is a school where the English language and literature, history, and mathematics are taught. The manufactures of Patna are not very important; and the chief trade is in opium, rice, indigo, wheat, and sugar. A great deal of traffic is carried on upon the Ganges, and Patna is a station on the East India railway. Patna was taken by the British in 1764, when they defeated the troops of the nabob of Bengal under its walls. A monument is erected in the city to the memory of 200 of their countrymen who were cruelly murdered by the nabob a few months before his defeat.

PATOOK, or PATUCA, a river of Honduras, falling into the bay of Honduras, about 110 m. E. of the port of Truxillo. It rises in the heart of the department of Olancho, in the vicinity of the city of Juticalpa, and is formed by the junction of the rivers Jalan, Tinto, Guayape, and Guallambre, all celebrated for their gold washings. Through the coast alluvions, for a distance of 60 m., it is a deep and navigable stream; but above that point it is interrupted by numerous rapids, and among them what is called the Portal del Infierno, a deep and narrow chasm, through which the river rushes with irresistible force. The principal mouth of the Patook opens directly into the sea, and is obstructed by a bad and shifting bar, with only from 8 to 10 feet of water. The second mouth of the Patook opens into Brus or Brewer's lagoon, but will not admit vessels of more than 6 feet draft. The total length of the river is about 150 m., and it affords the best means of communication with the large and rich department of Olancho.

PATRAS, PATRASSO, or BALIABARDA (anc. *Patræ*), a fortified seaport town of Greece, in the N. W. part of the Morea, on the gulf of the same name, capital of the prefecture of Achaia and Elis; pop. about 8,000. It is situated partly on a spur of Mt. Voidhia, on which stood the ancient town, and principally on the level plain below it. The streets are broad and straight, intersecting one another at right angles; the houses are mostly of one story, being built low as the best security against earthquakes. The most important public building is the castle, which is situated on the site of the ancient acropolis. Patras is the principal seat of the foreign trade in the Morea. For the protection of the harbor, which is unsafe and exposed to heavy seas, a mole has been constructed.—The ancient city was founded by the Ionians, from whom it was wrested by the Achæans under Patreus; from him the city received its name of Patræ. During the Peloponnesian war it alone of the Achæan towns embraced the side of the Athenians. In 419 B. C. Alcibiades persuaded the inhabitants to join the city and port by a long wall. It was a member of the Achæan league, and during the war between the Achæans and Romans it suffered extremely, and became an insignificant town. In that condition it remained until the reign of Augustus, who selected it as one of the two Roman colonies established on the W. coast of Greece. It was destroyed by an earthquake in the 6th century; subsequently it was a dukedom of the Byzantine empire; was sold to the Venetians in 1408; was taken by the Turks in 1446, was after a vigorous defence retaken by Andrea Doria in 1532, and again recovered by the Turks, in whose hands it remained until the Greek revolution. It was the first city to raise the standard of revolt, but during the war the castle was held by a Turkish garrison, which capitulated in 1828 to a French force.—The gulf of Patras lies between Ætolia and the N. W. coast of the Morea, and between the gulf of Lepanto on the E. and the Ionian sea on the W. Its greatest length is 50 m., its greatest breadth 14 m. Its navigation is difficult, and during the winter months sometimes dangerous.

PATRIARCH (Gr. *πατριάρχης*, chief of a race), a title applied to the fathers or heads of generations mentioned by the sacred writers from Adam to Jacob. After the destruction of Jerusalem it was the title of the chief religious rulers of the Jews in Asia; and in early Christian times it became the designation of certain bishops who exercised superior jurisdiction. These were the bishops of the 5 chief dioceses of Rome, Constantinople, Alexandria, Antioch, and Jerusalem. Certain other bishops were likewise termed patriarchs in course of time, especially those of newly converted nations. In modern times patriarchs have jurisdiction over all the bishops and metropolitans or archbishops of their patriarchates, but their authority extends little beyond the right of convoking councils and exercising a general watchfulness over the conduct of their subordinate prelates. The patriarchs at present in communion with the see of Rome are those of Constantinople, Alexandria, Antioch, Jerusalem, the East Indies, Venice, and Lisbon, beside those of the Melchites, Maronites, and Syrians at Antioch, Armenians in Cilicia, and Nestorians (Chaldeans) nominally at Babylon. In the orthodox Greek church the title of patriarch is attached to the sees of Constantinople, Alexandria, Antioch, and Jerusalem, and various Christian sects of the East have patriarchs.

PATRICIANS (Lat. *patricii*, from *pater*, a father), the name given by the Romans to the members and descendants, by blood or adoption, of the original houses of which the *populus Romanus* was wholly composed until the establishment of the plebeian order. They were at first divided into the tribes of Ramnenses, Titienses, and Luceronses, each tribe consisting of 10 *curiæ*, and each curia of 10 *gentes*, or in regard to representation and war of 10 *decuriæ*. The *gens*, all the members of which bore the same gentile name, sent its leader to the senate. Originally the two tribes of Ramnenses and Titienses enjoyed exclusive political privileges, but the Etruscan tribe of Lucerenses was admitted to the same rights by Tarquinius Priscus, and the number of senators, which before had been 200, was in consequence increased to 300. To distinguish the old senators from the new, the former were called *patres majorum gentium*, and the latter *patres minorum gentium*. At this period, all the population who were not patricians were clients or slaves. After the formation of the plebeian order, the patrician became a real aristocracy of birth, which held possession of all the civil and religious offices. No matter how poor he was, a patrician could not become a plebeian unless he voluntarily left his gens and curia, and gave up its obligations and privileges; and no matter how wealthy he was, a plebeian could not become a patrician except in accordance with the *lex curiata*, and this was rarely the case. At the end of the republic the number of patrician families had diminished to about 50, and both Julius Cæsar and Augustus and the succeeding emperors found it necessary to raise plebeians to the patrician rank. The long struggle in which the plebeians were engaged for the possession of their political rights resulted in their complete victory, only a few insignificant offices being retained by the patricians. The formation of the new aristocracy, founded upon wealth and upon the holding of the offices of consul, prætor, and curule ædile, rendered the old patrician families of still less account. During the empire the Roman citizens were divided into the two classes of *populus* and *patricii*. At the accession of Constantine the patrician families had almost entirely died out, and that monarch made it a personal title instead of a hereditary distinction. It was granted to all, without regard to birth, who had made themselves eminent by their services to the empire or the emperors. With the exception of the consuls, they constituted the highest rank in the state. Those members of the patrician body who were in actual service, as usually most of them were, went under the name of *patricii præsentales*; the others were called *patricii codicillares* or *honorarii*. This distinction was conferred by most emperors with much caution, but some granted it even to eunuchs. It was also conferred at times on foreign princes; and the governor of Ravenna, who exercised the power of a supreme magistrate, was styled indifferently exarch or patrician. After the loss of Italy, the Romans conferred this title on their rulers and protectors, such as Charles Martel and his descendants; and in this capacity Henry IV. claimed the right to depose Pope Gregory VII. During the middle ages families entitled patrician sprang up in many of the cities. In Venice members of the great council and their descendants were called patricians. After 1297 no person was created patrician, but all descendants of those who had belonged to that body became members by right at the age of 25. In Rome, Genoa, and other cities of Italy, the title of patrician was and is still used to denote a member of the nobility.

PATRICK, a S. co. of Va., bordering on N. C., and drained by the Dan, Smith's, and North and South Mayo rivers, all of which have their sources in the Blue ridge, which forms its N. W. boundary; area about 500 sq. m.; pop. in 1860, 9,359, of whom 2,070 were slaves. It has a mountainous surface, and is noted for its picturesque scenery; much of the soil is fertile, and iron ore is abundant. The productions in 1850 were 248,858 bushels of Indian corn, 90,441 of oats, 12,755 of wheat, 429,699 lbs. of tobacco, 8,523 of wool, and 66,957 of butter. There were 2 grist mills, 2 tanneries, 1 furnace, 1 forge, 18 tobacco factories, 12 churches, and 836 pupils attending public schools. Value of real estate in 1856, $1,321,719, showing an increase since 1850 of 76 per cent. Capital, Taylorsville.

PATRICK (PATRICIUS), SAINT, the patron saint of Ireland, born, according to most authorities, near the site of Kilpatrick, at the mouth of the Clyde, in Scotland, in 372, died at Down, Ulster, probably in 464. At the age of 16 he was carried captive to Ireland by a band of marauders, but made his escape after 6 months and reached Scotland. Carried off a second time, and again escaping, he resolved to become a missionary to the Irish, was ordained in Scotland, and after a long preparation was consecrated bishop. Having previously, according to some accounts, visited Gaul and perhaps Italy, he passed over to his chosen field of labor about 432, and preached the gospel with such extraordinary effect that, although not absolutely the first to introduce Christianity into that country, he has always received the credit of its general conversion. He baptized the kings of Dublin and Munster, and the 7 sons of the king of Connaught, with the greater part of their subjects, and before his death had converted almost the whole island to the faith. St. Bernard testifies that he fixed his metropolitan see at Armagh, and it appears that he appointed several other bishops, with whom he held councils to settle the discipline of the church which he had planted. In his old age he wrote his "Confession," the authenticity of which, however, is doubted. It may be found in Sir James Ware's edition of the works of St. Patrick (8vo., London, 1658). The Roman Catholic church keeps his festival on March 17. A popular legend ascribes to him the banishment of all venomous creatures from the island by means of his crosier or staff, which Ralph Higden in his "Polychronicon" mentions as being kept with great veneration at Dublin in 1360.

PATRICK, SIMON, an English prelate and author, born in Gainsborough, Lincolnshire, in 1626, died May 31, 1707. He was the son of a mercer in his native town, and was educated at Queen's college, Cambridge, where he received a fellowship in 1648. In 1658 he was presented with the living of Battersea, and about this time published his "Mensa Mystica, or a Discourse concerning the Sacrament of the Lord's Supper; to which is added a Discourse concerning Baptism." The following year he produced a treatise entitled "The Heart's Ease, or a Remedy against all Troubles;" and in 1660 another under the title of "Jewish Hypocrisy, a Caveat to the Present Generation." By the earl of Bedford he was presented with the living of St. Paul's, Covent Garden, where he remained several years. In 1679 he became dean of Peterborough, in 1689 bishop of Chichester, and in 1691 bishop of Ely. He published, beside a translation of Grotius *De Veritate*, a large number of works, chiefly devotional, the most important of which was his "Commentary and Paraphrase on the Old Testament" (14 vols. 4to., London, 1695); it extends to Solomon's Song, and was completed by Lowth and Whitby for the whole Bible. Dr. Patrick's writings gave him considerable reputation in his day, and are still valued. He was selected to revise the collects of the whole year after his appointment as one of the commissioners for the review of the liturgy, but the revision never came into use. The first collected edition of his works was printed by the Oxford press in 9 vols. 8vo. (1859).

PATRIMONY OF ST. PETER, the name formerly applied to a part of the Papal States, consisting mainly of the territory given to the church by the countess Matilda in 1077. It corresponds to the modern delegation of Civita Vecchia, together with the S. part of Viterbo, and the N. W. part of the comarca di Roma.

PATROCLUS, a Greek legendary hero, the inseparable friend of Achilles, and son of Menœtius of Opus. While a boy he accidentally killed Clysonymus, and in consequence was sent to the court of his kinsman Peleus, and brought up with Achilles, whom he accompanied in the expedition against Troy. He occupied a prominent position in the siege until his friend absented himself from the conflict by reason of his quarrel with Agamemnon, when Patroclus also withdrew; but the affairs of the Greeks becoming desperate, he obtained from Achilles his armor and his troops, and with their assistance drove back the Trojans and saved the ships from burning. During the conflict he was struck senseless by Apollo, and was killed by Euphorbus and Hector, the latter taking possession of the armor. In the fight that ensued for the dead body the Greeks were successful. His ashes were buried under a mound, which not long afterward was opened to receive the dead body of Achilles, who had revenged his friend by the death of Hector.

PATRON (Lat. *patronus*, from *pater*, a father), an appellation given by the Romans to a patrician who had plebeians, called clients (see CLIENT), under his protection, or to a master who had freed his slave. When a slave was manumitted, he himself was called *libertus* or freedman, and his master *patronus*, and between them existed certain duties and privileges, which however seem to have been more fixed by custom than by law. The patron took the freedman under his protection, and the freedman owed to his former master respect and gratitude, and was bound to support both him and his children in cases of necessity. By a special agreement the *libertus* after he was freed took an oath to make an offering to the patron of gifts and services, the latter being of two kinds, services of respect and services of labor. The former ended with the death of the patron, but the latter were due also to his heirs. The patron was not entitled to any services that were either dangerous or disgraceful; and by the *lex Julia et Papia Poppæa* freedmen, with a few exceptions, were discharged from all requirements as to gifts and services, if they were the parents of two children who were in their possession, or were the parents of one child 5 years old. The most important relation existing between the patron and freedman was the right of the former in certain cases to become the heir of the whole or a portion of the property of the latter. By the laws of the 12 tables, if a freedman died intestate without heirs of his own, the patron became his heir, as he was supposed to stand in the relation of an *agnatus*. By the *lex Papia*, when a freedman left property valued as high as 100,000 sesterces, some of it went to the patron whether a will had been made or not. If there were 3 children, however, the patron had no share. These rights of a patron extended to his direct but never to his collateral heirs, and the privileges of the *liberti* in regard to the succession of property extended only to those who were Roman citizens and not to the Latin freedmen. The latter "lost their life and their liberty at the same time," and their property passed into the hands of those who had manumitted them. In many other points the succession to their property differed from the succession to that of the Roman freedmen, and on this subject laws were passed during the reigns of Claudius and Trajan. These regulations were radically changed under Justinian, who gave to the Latin freedmen the same privileges as were possessed by the Romans. If a freedman was guilty of ingratitude, his patron might punish him summarily, and in later times he had the right to relegate him some distance from Rome. In the time of Nero an effort to pass a decree enabling a patron to reduce his freedman again to slavery failed, but afterward it was successful. The patron lost his rights, however, if he neglected to support his freedman in a case of necessity. The *libertus* assumed on his manumission the gentile name of his patron.—In the canon law, a patron is a man who has the right of disposing of a benefice, from the fact that it was founded or endowed by him or by those to whose rights he has succeeded. This right is said by some to have sprung up about the close of the 4th century, and was probably intended to offer inducements to the wealthy to found churches with the privilege of naming the person who should officiate. In the Roman Catholic church, a patron is a saint under whose protection a person places himself, often from bearing the same name, or who holds that relation to a community; or a saint to whom a particular church or order is dedicated.

PATTERSON, Daniel T., an officer of the U. S. navy, born in the state of New York, died in Washington, Aug. 15, 1839. He entered the navy as a midshipman in 1800, and was attached to the frigate Philadelphia, Capt. William Bainbridge, when she ran upon a reef of rocks off Tripoli in Oct. 1803, and, being in a defenceless condition, surrendered to a flotilla of Tripolitan gun boats. (See Bainbridge, William.) He remained a prisoner in Tripoli until peace was concluded with that regency in 1805. In 1807 he was promoted to the rank of lieutenant, and in 1813 to that of master commandant. In 1814 he commanded the naval forces of the United States at New Orleans, and coöperated so ably with Gen. Jackson in the defence of that city that he received the thanks of congress. He was promoted to the rank of captain in Feb. 1815, served as navy commissioner from 1828 to 1832, and in command of a squadron in the Mediterranean from 1832 to 1835. He died while in command of the navy yard at Washington.

PATTISON, Robert Everett, D.D., an American clergyman and teacher, born in Benson, Vt., Aug. 19, 1800. He was graduated at Amherst college in 1826, was soon after appointed a tutor in Columbian college, D. C., was ordained as a Baptist minister in Sept. 1829, at Salem, Mass., and in March, 1830, settled as pastor of the first Baptist church in Providence, R. I. From this post he was called to a professorship in Waterville college, Me., and in 1836 to the presidency of that college, which he resigned in 1840. He then returned to his pastoral charge at Providence. In 1843 he was elected one of the corresponding secretaries of the Baptist board of foreign missions. In 1846 the trustees of the western Baptist theological institute, at Covington, Ky., elected him president and professor of Christian theology. In this position he continued till 1848, when by an act of the Kentucky legislature, subsequently decided by the supreme court of the state to be unconstitutional, the control of the seminary was wrested from the trustees and placed in other hands, and the professors were dismissed. Dr. Pattison was immediately appointed to a similar professorship in the Newton theological seminary, Mass., from which, after 5 years' service, he was again called to the presidency of Waterville college in 1853. After some years he resigned on account of his health, and he is now at the head of the Oread female institute at Worcester, Mass. He received the degree of D.D. from Brown university in 1838. Beside contributions to periodicals and one or two addresses, he has written a "Commentary, Explanatory, Doctrinal, and Practical, on the Epistle to the Ephesians" (Boston, 1859).

PATUXENT, a river of Md., rising about 20 m. from Frederic City, and after a S. E. course of about 40 m. and a nearly S. course of 50 m., discharging itself through an estuary 2 or 3 m. wide into Chesapeake bay. It forms the dividing line between Montgomery, Prince George, Charles, and St. Mary counties on the S. and W., and Howard, Anne Arundel, and Calvert counties on the N. and E. Small vessels can ascend it 50 m. to Nottingham.

PAU, a town of France, capital of the department of Basses-Pyrénées, on the right bank of the Gave de Pau, 470 m. S. by W. from Paris; pop. in 1856, 17,238. It is regularly laid out and well built, having a broad main street, several squares, and fine public walks on its outskirts. Its situation on a precipitous height is delightful; in the vicinity are picturesque valleys, and on the S. the eye rests in the distance upon the snowy peaks of the Pyrénées. The charm of the scenery and the mild and healthful climate attract to Pau a considerable number of foreign visitors and permanent residents. Linen cloths, renowned as *toiles de Béarn*, and fine table cloths, tapestry carpets, and cutlery are manufactured.—Pau was founded in the 10th century; a viscount of Béarn built a strong castle on the top of a hill, and having marked the limits of the ground with stakes or *paus*, the town which formed itself around retained the appellation. In the 14th century the castle was rebuilt by Gaston Phébus, count of Foix, and the city became the chief town of Béarn. The castle was enlarged and embellished during the 16th century. Henry IV. was born there; and the room where this event took place has still its ancient portraits and furniture, as well as the tortoise shell that was used as a cradle for the infant prince. The castle itself was repaired and renovated in the time of Louis Philippe; it is one of the summer resorts of Napoleon III. and his court. A marble statue of Henry IV. stands in the vestibule of the castle; and two others, one of white marble erected in 1843, and one in bronze, adorn the principal squares.

PAUL, the name of several popes, of whom the most distinguished are the following. I. Paul III. (Alessandro Farnese), born in Rome in 1465, died in Nov. 1549. He succeeded Clement VII. in 1534, and summoned a general council to meet at Mantua, but afterward transferred it to Trent, where the first session was held in Dec. 1545. He made an abortive league with the emperor and the republic of Venice against the Turks, and induced Francis I. and Charles V. to conclude a truce for 10 years at Nice (1538), which was not however observed. He excommunicated Henry VIII. of England, established the inquisition at Naples, approved the society of Jesus, sent a contingent of 12,000 foot and 1,000 horse to join the emperor's forces in Germany against the Protestants, and opposed the religious pacification called the *interim* granted by Charles V. in 1547. He exerted himself zealously to subdue the turbulent feudatories of the Papal States, and expelled the powerful Colonna family from Rome. Before becoming a priest he had a son and daughter, the former of whom was created duke of Parma and Piacenza. II. Paul IV. (Giovanni Pietro Caraffa), born in 1476, died Aug. 18, 1559. He succeeded Marcellus II. in 1555, and displayed an energy in his administration which had not been expected from his advanced age and previous studious habits. He concluded an alliance with Henry II. of France against the emperor Charles V. (Dec. 1555), and afterward against Philip II., in consequence of which his dominions were invaded by the duke of Alva, and the Spanish troops advanced almost to the gates of Rome. A peace however was concluded in 1557. The emperor Ferdinand I. having accepted the throne without consulting the holy see, the pope dismissed the imperial ambassador, and Ferdinand accordingly did not come to Rome to be crowned, an omission which was imitated by all the succeeding emperors. Paul IV. was a zealous opponent of the Protestants, against whom he issued a bull in 1559, and coöperated earnestly with Queen Mary in her attempts to restore Catholicity in England. He introduced the inquisition into his states, labored assiduously for the reformation of the clergy, and founded the order of Theatines, who took their name from the archbishopric of Theate or Chieti, which he had held before he became pope. He raised his nephews to the highest honors in the state, and made one of them a cardinal, though his past life had been that of a soldier and a libertine; but hearing that they abused their power, he banished them from Rome in 1559. He was hated by his subjects, who rose in tumult on the news of his death, and threw down his statue, crying: "Death to the Caraffas." III. Paul V. (Camillo Borghese), born in Rome in 1552, died Jan. 16, 1621. He succeeded Leo XI. in 1605, and soon after his accession was involved in a dispute with the republic of Venice respecting the foundation of religious houses, the alienation of charitable bequests, and the trial of ecclesiastics by lay tribunals. He excommunicated the doge and the senate, and laid the republic under an interdict which the senate forbade to be published, and which only the Jesuits, Theatines, and Capuchins observed. These three orders were consequently banished. The pope on his side prepared to take up arms; but fearing, from an intercepted letter of Father Paul Sarpi, that advantage would be taken of such an event to introduce Calvinism into Venice, he invited the mediation of Henry IV. of France, and the dispute was settled by a compromise in 1607. The condemnation by the parliament of Paris of the *Defensio Fidei* of Suarez was the cause of angry relations with France in 1614. In the mean time Paul had devoted himself with great zeal to reforming the administration of his temporal government, embellishing Rome, and restoring ancient monuments. He exerted himself to send missionaries to the East, and received embassies from Japan, from several princes of India, and from Congo.

PAUL, Father. See Sarpi, Pietro.

PAUL I., Petrovitch, emperor of Russia, born Oct. 12, 1754, assassinated March 23, 1801. A son of Peter III. and Catharine II., Paul inherited the weakness and pusillanimity of his father, with few of the intellectual qualities of his mother. The hatred which his parents bore to each other, and which resulted in the assassination of Peter at the instigation of his wife, exerted a baneful influence upon the earliest development of Paul's mind and character. His father hated him as the offspring of a hated wife, and intended to disinherit him. Catharine, having assumed the reins of government (1762), pretended to give him an education worthy of the heir of a great empire; but even before he grew up to manhood her dislike of him had become so violent that she compelled him to live at a distance from the capital, persecuted him in every conceivable manner, surrounded him with spies, left him in absolute want of the necessaries of life, and took not the slightest pains to conceal her contempt of him. Such influences necessarily left their mark upon his temper. He became morose, revengeful, craven toward his mother, yet wilful and tyrannical toward inferiors, dead to ambition, and indifferent to the requirements of his station. At the age of 19 he was married by order of his mother to a princess of Hesse-Darmstadt, and after her death in 1776 to a princess of Würtemberg. His domestic felicity recompensed him in some degree for the contemptuous manner in which he was excluded from all participation in government affairs. His second wife bore him 4 sons (Alexander, Constantine, Nicholas, and Michael) and 5 daughters. The former were taken from their parents by order of Catharine, and brought up under her direction. In 1780 Paul travelled through Poland, Germany, Italy, France, and Holland. Afterward he took part in the war against Sweden, but even then his mother purposely deprived him of every opportunity of becoming familiar with the duties of his position. He bore this treatment in a dull, patient manner, hoarding up revenge for a future day. At last his deliverance came. Catharine died Nov. 17, 1796, and Paul ascended the throne. One of his first acts was to cause funeral honors to be paid to his murdered father, and he ordered the remains of his mother's former favorite, Prince Potemkin, to be disinterred and thrown into a ditch on the wayside. To undo whatever Catharine had done seemed to be his only guiding principle. He disbanded her armies, declared peace with Persia, disapproved of her policy toward Poland, liberated Kosciuszko and the other Polish prisoners, decreed that the female line should henceforth be excluded from succession, and invited his eldest son to an active participation in the administration of the country. But the rejoicings of the people over these happy beginnings were premature. The defects of his education soon became apparent. His narrow-minded egotism, fostered by the seclusion of his youth, combined with his nervous and fitful temper to render him an execrable tyrant. His most puerile whims and caprices were raised to the dignity of laws, and a well organized secret police was constantly active in discovering victims of his wrath. He required those who were admitted to his presence to kneel before him. When he drove out, he would punish with the utmost cruelty whoever did not alight from their carriages and prostrate themselves as he passed. He disliked round hats, and authorized any one to tear them from the heads of their wearers. He would allow no one to keep a dog near his residence. These and a thousand other petty oppressions exasperated the people even more than his hatred of liberal ideas, his decrees forbidding the importation of all books or newspapers printed in French, and similar measures. His policy in regard to the great events in western Europe was as inconsistent and capricious as his administration of the internal affairs of his empire. At first he became a party to the coalition against revolutionary France, and his army of over 100,000 men obtained some successes in Italy, Switzerland, and Holland; but having afterward suffered severe reverses, Paul became disgusted with his allies, expelled the French refugees from Russia, and endeavored to get up a coalition against Great Britain. In this he succeeded so far that Denmark, Sweden, and Prussia joined him in a treaty of armed neutrality. But his hatred against Great Britain had become so violent that he was far from being satisfied with this success. Through the columns of the "St. Petersburg Journal" he challenged to personal combat all those kings who were unwilling to take sides with him against England. At last his capriciousness and despotism reached a pitch which verged on downright madness. A conspiracy was formed against his life by a number of noblemen, among whom Counts Pahlen and Zuboff, Generals Benningsen and Uwaroff, and Lieut. Col. Tatisheff were the most conspicuous. To his son Alexander it was represented by them that they had no other object than to compel the emperor to abdicate the throne. They forced their way into Paul's chamber late at night, and presented for his signature a letter of abdication. He refused to sign, whereupon Zuboff knocked him down and kneeled upon him, and, the other conspirators joining in the deed, the emperor was murdered in the most horrible manner within hearing of his eldest son and successor, and it has even been said that his second son Constantine actually assisted in the butchery.

PAUL, Regular Clerks of St. See Barnabites.

PAUL, Saint, in sacred biography, the first Christian missionary who extended his labors beyond the limits of the Jewish people, the first Christian teacher who maintained the equality of Jews and gentiles under the new dispensation, and admitted the latter to the full participation of Christian privileges without the execution of the ceremonial law. Paul is ranked by the Christian church with the 12 apostles, and claims that rank for himself in his epistles. Our knowledge of his history is derived from the Acts of the Apostles and incidental notices in his letters to the churches. Many attempts have been made to arrange these materials in a systematic biography, of which the most comprehensive and popular is the "Life and Epistles of St. Paul," by Conybeare and Howson (London, 1854). For the critical student the works of Wieseler and Baur are the most important. Paul was a Grecian or Hellenistic Jew, by birth and country—that is, a Jew born without the limits of Palestine—but, until his conversion, a rigid Hebrew of the sect of the Pharisees, by parentage and training as well as by personal conviction. His original and Jewish name Saul appears to have been dropped and that of Paul adopted soon after his accession to the Christian ministry; for what cause it is impossible to say, nor whether the name Paul had ever been used as one of his appellations before his conversion. He was born in Tarsus, the metropolis of Cilicia. The precise date of his birth is unknown, but is proximately determined by the circumstance that Paul is spoken of as a young man at the time of the martyrdom of Stephen. The best chronologers place that event as late at least as A. D. 38. Accordingly, Paul can hardly have been born earlier than A. D. 8, or later than 12. His family enjoyed the right of Roman citizenship, either as *libertini* (slaves honorably manumitted), or in consequence of important services rendered to the state. There is reason to believe that the youth of Paul partook of the literary advantages which distinguished his native city. The traces of philosophic thought which pervade his epistles, and his evident familiarity with the Greek poets, discover a mind imbued with gentile as well as with Jewish lore. According to rabbinical law and custom, which required every male Jew to be taught some manual art, he learned the trade of a tent maker, to the practice of which he was afterward indebted in part for his support. (Acts xviii. 3, xx. 34; 1 Cor. iv. 12.) His knowledge of the law and the prophets and other essentials of a Jewish education was obtained at Jerusalem under the tuition of Gamaliel, the most learned rabbi of his time. Paul's first appearance on the stage of history connects itself with the martyrdom of Stephen, to which he was a party, being at that time a student at Jerusalem, devoted to the Pharisaic interest in that city, and probably attached to the congregation of the "libertines." From this time forth he became a zealous persecutor of the Christian church, volunteering his services to the sanhedrim for that purpose, and holding a commission from that body to ferret out, both at Jerusalem and in "strange cities," and bring to trial the confessors of the new faith. It was in the discharge of this commission, and while bound to Damascus on one of these errands, that he experienced a sudden and miraculous conversion, which changed the whole course of his life, not only arresting his work of persecution, but impelling him to become the indefatigable advocate and apostle of the faith he had persecuted. The three accounts of the matter in the Acts (ix. 7, xxii. 9, and xxvi. 14) differ in regard to the participation of Paul's companions in this remarkable experience, but all agree in their representation of the impression made on Paul himself of a voice addressing him in the name of Christ and bidding him forbear the persecution of his church. Struck with temporary blindness by this vision, he was brought to Damascus, where, after 3 days' sojourn, he recovered his sight at the hands of a disciple named Ananias and received Christian baptism. The next 3 years were spent in Arabia and Damascus, after which the apostle made a brief visit to Peter at Jerusalem, and then returned to his native city. Meanwhile a new centre of Christian influence had established itself at Antioch, the capital of Syria, and thither Paul now went at the solicitation of Barnabas, one of the leaders of that movement, who had come to Tarsus to secure his coöperation. Here he remained for a year or more, engaged in expounding and propagating the new faith. A famine which visited Judæa in the reign of the emperor Claudius (A. D. 45), induced the church at Antioch to send pecuniary aid to the Christians at Jerusalem, and Paul and Barnabas were deputed to convey the money collected for that purpose. (Acts xi. 29, 30.)[*] Having accomplished this eleemosynary mission, he returned to Antioch and made that city his head-quarters and the starting point of the missionary tours in Asia Minor and Europe which he now undertook in behalf of the faith. Three distinct journeys from this point of departure are recorded. The first, in which Paul was accompanied by Barnabas, and for a portion of the way by John Mark, who left them on the coast of Asia Minor, embraced the island of Cyprus from east to west and three of the southerly provinces of Asia Minor, viz., Pamphylia, Pisidia, and Lycaonia. In the principal cities of these countries the missionaries established Christian churches after the model of that at Jerusalem. Some time after his return to Antioch, where Paul now resumed his home ministry, the attempt was made by Judaizing Christians sent from Jerusalem for that purpose to impose the Mosaic ritual on the gentile converts. The movement was strenuously resisted by the leaders of the Antioch church, and Paul and Barnabas were sent to Jerusalem to debate and arrange this difficulty with the apostles and elders in that city. This first Christian council is assigned by different authorities to dates ranging from the year 47 to the year 53. We incline with Wieseler to place it at 50. The two delegates, after a satisfactory adjustment of this question, returned to Antioch, and with them two emissaries from Jerusalem. With one of the latter, Silvanus or Silas, Paul soon after undertook his second missionary tour, having previously separated from Barnabas in consequence of a dispute which arose between them relative to John Mark, whom Barnabas would have to go with them, but whom Paul rejected on account of his desertion of them at Perga in their first expedition. The missionaries visited Cilicia and the regions already traversed by Paul, and the churches founded by him in Pamphylia and Lycaonia. At Lystra they were joined at Paul's solicitation by Timothy, a young Greek who had embraced the Christian faith. They extended their travels through the central provinces of Asia Minor, Phrygia and Galatia, then to Mysia, and so to the western coast, where, at Troas, Paul resolved, in consequence of a dream which he interpreted as a call from God, to cross over to Europe. Accordingly the company, of which Luke, it is supposed (from the use of the first person plural which occurs here for the first time in the narrative), was one, took ship at Troas, and after a short run landed at Neapolis on the Macedonian coast. They thence proceeded to Philippi, where the Christians came into collision with a gentile party who trafficked in divination, and who inflamed the minds of the people against Paul and Silas. The apostle and his friend were publicly scourged and thrust into prison, but honorably released the next day, when the gaoler, whom Paul had baptized, represented to the magistrates that they were Roman citizens. In Thessalonica, where they made many converts among the Hellenists, they met with a strong opposition on the part of the stricter Jews, who followed them to Berea, where also success had attended their efforts. The "brethren," thinking that Paul's life was endangered, sent him away in the charge of friends who brought him to Athens. Here he held public disputations with philosophers of the leading schools, and at their invitation gave a public exposition of his doctrine in the areopagus, pronouncing on this occasion the remarkable speech on the nature of Deity—the most striking and important of all the speeches recorded of him. From Athens he went to Corinth, then capital of the Roman province of Achaia, where he enjoyed the hospitality of a Jewish family recently banished from Rome under the edict of the emperor Claudius forbidding the residence of Jews in that city. He practised here his craft of tent maker, which was also that of his host (Aquila), and so relieved him of the burden of his support. He was soon joined by Silas and Timothy, and with their assistance, urged by a vision foretelling success, he ministered for a space of nearly two years to the people of Corinth; and having established a promising church, to which two of the epistles in our collection are addressed, he returned to Antioch, touching at Ephesus and visiting Jerusalem by the way. After an interval of rest at Antioch, in the autumn, it is supposed, of the year 54, Paul entered on the third and last of his missionary journeys. Passing through various provinces of Asia Minor, he arrived at Ephesus, where the ground had been prepared for him by Aquila and Priscilla, with Apollos their convert. Here he remained during a period of 3 years, laboring with marked success, inducing, among other fruits of his ministry, the *goetæ*, or magicians, to abandon their practice and to burn their amulets—a pecuniary sacrifice of 50,000 drachmas, equivalent to $8,000 or $9,000. A hostile encounter with the silversmiths of that city, who traded in models of the temple of Diana, and who conceived their business to be endangered by Paul's preaching, hastened his departure from Ephesus. He proceeded to Macedonia, and thence to Greece; then returning to Macedonia, he crossed over to Troas, and from there, by way of Assos and the islands of Chios and Samos, he went to Miletus, accompanied by Timothy, Luke, and other disciples. At Miletus he tarried long enough to receive a deputation of the elders of the church at Ephesus, whom he had invited to meet him, and to whom he communicated his parting instructions, bidding them a final and affectionate farewell. He then embarked with his company for Rhodes and Tyre on his way to Palestine, whither he went, as he says, "bound in the spirit;" his friends in every city where he stopped on the route endeavoring to dissuade him, "the Holy Spirit," in every city, "witnessing that bonds and afflictions" awaited him; his own instinct in spite of prophecies and entreaties urging him on. The party arrived at Jerusalem at the feast of Pentecost in the year 58; they presented themselves before James and the other elders of the church, and Paul reported the many-sided success of a mission embracing a considerable portion of the Roman empire in its wide endeavor. The Christian party at Jerusalem, under the influence of the Jewish capital, and anxious to conciliate their countrymen, so far from renouncing the law of Moses, were especially scrupulous in their observance of its rites and requirements. Aware that Paul had rendered himself obnoxious to Judaizing Christians by his liberal views in relation to this matter, the elders persuaded him by an act of public conformity to humor their prejudices and disarm their hostility. At their suggestion he united with a party of four who were then discharging a Nazaritic vow, and was seen with them in the temple fulfilling the ritual purification prescribed by Levitical law. This concession was not attended with the expected result. The measure which was to have secured him against the hostile zeal of his opponents only served to betray him into their hands. Seen in the temple, he was seized on a charge of plotting against the Mosaic religion, and accused of bringing gentiles into the sacred courts. The Roman guard rescued him from the hands of the mob, and, on the discovery of a conspiracy against his life, disclosed by a nephew of Paul then residing at Jerusalem, he was sent to Cæsarea to Felix, proconsul of the province of Judæa. Felix, though seemingly satisfied of his innocence, for the sake of conciliating the Jews detained him a prisoner at Cæsarea. After the expiration of two years Felix was succeeded by Festus, and Paul was then offered the opportunity of a trial before the national council at Jerusalem, which he declined, aware of the impossibility of obtaining a fair hearing from that tribunal. Despairing of justice at the hands of his countrymen, he appealed by right of his Roman citizenship to the government at Rome, and to Rome accordingly he was sent. He reached that destination in the spring of the year 61, after the long and perilous voyage and shipwreck described in the Acts (xxvii.). While there he was permitted as a special favor to reside in a hired lodging instead of being thrust into a dungeon or confined in the barracks. Here he remained two years, and, though under constant military guard, was allowed free intercourse with his countrymen and others who chose to visit him. He was thus enabled to prosecute his missionary labors, which he appears to have done with success. Members of the imperial household were among his converts. (Philipp. iv. 22.) Here the history leaves him, and leaves us to conjecture his subsequent fortunes. The supposition of Baur, Wieseler, and many others is that he never recovered his liberty, but remained prisoner at Rome until he perished at the hands of the executioner, a martyr to his faith; but there is a widely accepted tradition that he was tried and acquitted, that he left Rome, made other missionary tours, was once more arrested, again brought to Rome, tried, condemned, and executed. It is even asserted that he passed two years in Spain, returning to Rome about 64, and suffering death by decapitation in 65, or according to some authorities Feb. 22, 68. The attentive reader of the New Testament will notice indications of the opposition, jealousy, and even persecution which Paul encountered at the hands of his fellow Christians of the Judaistic type. Other martyrs have suffered from the enemies of their faith. Paul suffered far greater trials from its professors; and when enumerating his hardships and his sorrows, he tops the climax with "perils by false brethren." (2 Cor. xi. 26.) This circumstance should be taken into the account in estimating the worth and force of a character which in moral heroism has no superior, perhaps no equal, in the world's annals.—Of the 21 epistles embraced in the canon of the New Testament, 14 are popularly ascribed to Paul and assigned to him in the current versions. Of these, the Epistle to the Hebrews is pronounced by many critics at the present day to be the work of some other hand. The genuineness of the pastoral epistles (the two to Timothy and the one to Titus), of Colossians and Ephesians, has also been called in question; and Baur even doubts the authorship of Philippians, Philemon, and the two Thessalonians, allowing as indisputably genuine only Galatians, Romans, and the two Corinthians. In this extravagant judgment few critics will agree with him. It is impossible to determine with precision the chronological order of the epistles. The two to the Thessalonians are placed first by most of the critics who admit their genuineness, and after them the Epistle to the Galatians. Then follow, in Wieseler's arrangement, 1 Timothy, 1 Corinthians, Titus, 2 Corinthians, Romans, Philemon, Colossians, Ephesians, Philippians, and 2 Timothy.

---

[*] It is a disputed question whether the visit to Jerusalem recorded in this passage, or the one recorded in ch. xv., or in ch. xviii., or neither of them, is identical with the one referred to in Gal. ii. 1. In regard to these visits of Paul to Jerusalem after his conversion, his own statement in the Epistle to the Galatians conflicts with the narrative in the Acts, and no criticism has yet succeeded in reconciling the two accounts. The apostle's own testimony would seem to be the highest authority; accordingly we have followed it in speaking of the first visit. But without rejecting the testimony of the Acts altogether—*i. e.*, without abandoning our only source of information in regard to the greater part of Paul's history—we cannot ignore the visits to Jerusalem mentioned in that document, and inextricably interwoven with the whole thread of the story, however impossible it may be to match them with the declarations in the Epistle to the Galatians.

PAUL, VINCENT DE, a saint of the Roman Catholic church and founder of the congregation of sisters of charity, born at Pouy, Gascony, in 1576, died Sept. 27, 1660. He was the 4th child of a pious peasant named Jean de Paul, who, having determined to educate him for the church, put him when 12 years old to learn Latin of the Franciscan friars at the neighboring town of Acqs (now Dax). He afterward became tutor in the family of a lawyer of the place, who sent him in 1596 to the university of Toulouse, where he passed 7 years, was ordained priest in 1600, and received in 1604 the degree of bachelor of divinity. In 1605, while on a voyage from Marseilles to Narbonne, he was captured by Turkish pirates, carried prisoner to Tunis, and after being several times sold became at last the slave of a renegade from Nice. Through the influence of one of his wives, who had heard Vincent singing sacred songs at his labor, this man resolved to return to Christianity, and in June, 1607, fled from the country with his slave and reached France in a little skiff. Vincent spent the next year in Rome, where he secured the friendship of Cardinal d'Ossat, who sent him to Paris on a secret errand to King Henry IV. in 1608, and afterward procured his nomination to the abbey of St. Leonard de Chaume in the diocese of Rochelle. About the same time he was appointed almoner to Queen Margaret of Valois. In 1613 he entered the family of Emmanuel de Gondi, count de Joigny, as tutor to his 3 sons, one of whom was afterward Cardinal de Retz. To his duties as preceptor he added the task of preaching to the peasantry of his patron's estates, particularly upon the necessity of confession; and so struck was the countess with the extraordinary results of his labors that she offered 16,000 livres to any religious community which should undertake the same work among her tenantry every 5 years. The offer however was not accepted, and it was reserved for Vincent himself to found a few years later a new congregation for such missions. Having obtained in 1622 the appointment of chaplain to the galleys at Marseilles, he devoted himself to the welfare of the wretched convicts with the intensest ardor, and, after sensibly ameliorating their mental and bodily condition, went to Paris to extend his reforms to the prisons in which they were confined while waiting to be sent to the seaports. He fitted up a separate building for them, and when absent himself caused two priests who had joined in his charitable enterprise to live in the prison. He next appears at Mâcon, as the apostle of the vast multitudes of thieves and beggars for whom that city was then notorious. In 1622 he was appointed director of the nuns of the order of the Visitation in Paris, and this position he retained until his death. In 1624 the countess de Joigny revived the project of establishing stated missions among the poor, and with the coöperation of her husband and the archbishop of Paris proposed to Vincent to undertake the establishment of a new order, which she promised to endow with 40,000 livres. Accordingly in 1625 Vincent, accompanied by two other priests, took up his residence in the college of the *bons enfants*, which had been given for the purpose by the archbishop, and laid the foundation of the congregation of priests of the mission, sometimes called Lazarists from the priory of St. Lazarus which they acquired soon afterward. The associates received royal letters patent in May, 1627, at which time they had increased to 5, and were erected into a congregation by Pope Urban VIII. in 1632. (See PRIESTS OF THE MISSION.) Beside the primary object of missions among the peasantry, Vincent now devoted himself to the spiritual improvement of the clergy. He established religious exercises for candidates for orders, to which the archbishop of Paris afterward obliged all his ecclesiastics to apply themselves for 10 days before ordination; he threw open his house to all who wished to spend a few days in prayer and meditation; and every week he held what he called spiritual conferences, to which the clergy resorted in great numbers. With the assistance of Cardinal Richelieu, who admitted him to his confidence and used to consult him in making ecclesiastical appointments, he opened in 1642 an institution in which young priests or candidates for the priesthood might fit themselves for the labors of the ministry by 2 or 3 years spent in prayer and pious exercises. The result of these efforts for the purification of the church answered his greatest expectations. In the mean time he had not been idle in providing for the sufferings of the poor. Wherever he preached it had been his custom to establish "confraternities of charity," composed of women who took upon themselves to search out and relieve the distressed, without however forming themselves into a regular order. In 1633 he determined to enlarge his plan by creating a sisterhood which should pursue the same objects under a sufficiently conventual organization to insure the permanence and most beneficial working of the enterprise; and accordingly he placed 4 young women who had volunteered their services under the charge of Mme. Le Gras, a noble lady who had been several years employed under his direction in visiting the confraternities and in other labors for the poor. Such was the origin of the sisters of charity. Their rule was drawn up by degrees in the course of some years, and Vincent lived to see 28 houses of the order established in Paris, beside others in various parts of Europe. The reformation of the hospitals, the establishment of an asylum for foundlings (see FOUNDLING HOSPITAL), the instruction of idiots at his priory of St. Lazarus, and continual labors among the convicts, are the next events which we have to record in his history. It is related (though the story has been questioned) that he once offered himself in the place of a convict more unfortunate than guilty, and wore the fetters of a galley slave for several weeks before he was recognized. During the famine which depopulated Lorraine in 1638–'9 he collected and distributed upward of 2,000,000 livres among the sufferers. He attended Louis XIII. in his last illness, and was appointed by Anne of Austria one of the 4 members of the "council of conscience" to whom was committed the distribution of ecclesiastical preferments. In the wars of the Fronde he incurred the groundless suspicion of being a favorer of Mazarin, and his convent of St. Lazarus was accordingly sacked by a mob. The last labors of his life were the foundation of an asylum for aged artisans of both sexes, and a hospital for all the poor of Paris, which was opened in 1657, a royal edict obliging every beggar in the metropolis to either enter this institution or work for his living. Between 4,000 and 5,000 chose the former alternative. Vincent was beatified by Benedict XIII. in 1729, and canonized by Clement XII. in 1737.

PAUL OF SAMOSATA, a heresiarch of the 3d century. He became patriarch of Antioch in 260, and by extortion and bribery acquired great wealth. He affected extraordinary pomp, caused the hymns of the church to be abolished and others sung in praise of himself, and surrounded himself with a number of young and beautiful women who attended him wherever he went. In defiance of the ecclesiastical canons he held the office of *ducenarius*, a sort of procuratorship under the emperor. He was an especial friend of Zenobia, the queen of Palmyra, who called him to her court, admired his eloquence, and disputed with him on religion. He taught that there was only one God, who is denominated the Father; that the Word or Wisdom of God was not a substance or person, but was in the divine mind as reason in men; that Christ was a mere man who acquired this Word or Wisdom of God, becoming by it both God and the Son of God, though both in an improper sense, and gradually acquiring his knowledge and virtues; and that the divine Word withdrew from him when he suffered. His opinions were condemned in a council held about 264, but he was allowed to retain his see on promise of retracting them. Failing however to keep his word, he was again condemned and deposed at the council of Antioch in 269. The favor of Zenobia enabled him to set this sentence at defiance until 272, when Zenobia was conquered by the emperor Aurelian. The whole matter was now referred to the see of Rome, and Paul, expelled from his church, passed the rest of his life in obscurity. He had a few followers, who called themselves Paulianists. They disappear from history about the 5th century.

PAUL (Friedrich Paul Wilhelm), duke of Würtemberg, a German traveller and naturalist, born in Carlsruhe, June 25, 1797, died at Mergentheim, Nov. 25, 1860. He was educated at the court of his uncle, King Frederic I., and from love for natural sciences and travel in May, 1817, he left the army of Würtemberg to devote himself to his favorite pursuits. After having travelled extensively through Europe, he crossed the ocean, and from 1822 to 1824 journeyed in North America, making rich collections in natural history, and especially in zoology, and subsequently published an account of his expedition in a work entitled "First Journey to North America" (Stuttgart, 1835). In a second journey to America, he paid special attention to the remains of the old Aztec civilization. He subsequently made several journeys to Algeria, England, France, and Austria, and in the spring of 1849 he visited America again, travelling over Texas, the entire west of the United States on both sides of the Rocky mountains, and South America, and in 1856 sailed for Europe. From his 4th voyage to the United States, and thence to Australia, he returned home in 1859 by way of Ceylon, Egypt, Trieste, and Vienna.

PAULCON. See Constantine Faulcon.

PAULDING. I. A N. W. co. of Ga., drained by branches of the Chattahoochee and Tallapoosa rivers; area, about 400 sq. m.; white pop. in 1860, 6,667; slaves in 1859, 478. Its surface is uneven and traversed by elevated ridges; the soil in the valleys is fertile. The productions in 1850, since which time its limits have been reduced by the formation of new counties, were 256,019 bushels of Indian corn, 24,062 of oats, 44,378 of sweet potatoes, and 1,489 bales of cotton. There were 12 grist mills, 8 saw mills, 4 tanneries, 15 churches, and 324 pupils attending public schools. Capital, Van Wert. II. A N. W. co. of Ohio, bordering on Indiana, drained by the Maumee and Anglaise rivers; area, 432 sq. m.; pop. in 1860, 4,945. Its surface is level, covered with forests, and the soil, a rich vegetable mould, is very fertile. The productions in 1850 were 41,699 bushels of Indian corn, 10,704 of wheat, 4,509 of oats, and 4,214 of potatoes. It is intersected by the Wabash and Erie and the Miami extension canals. Capital, Charloe.

PAULDING, Hiram, an American naval officer, born in New York about 1800. He is a son of John Paulding, distinguished in the revolutionary war as one of the captors of Major André. He entered the navy as a midshipman in 1811, and was in the squadron of Com. McDonough in the battle of Lake Champlain, for which service he received a sword from congress. In 1844 he attained the rank of captain, and in 1857, while in command of the home squadron, broke up an expedition against Nicaragua headed by Gen. William Walker. The main body of this expedition, commanded by Walker in person, landed in Punta Arenas in the harbor of Greytown, Nov. 25. Commodore Paulding arrived on Dec. 6 in his flag ship the Wabash, and on the 8th landed a strong force under the immediate command of Capt. Engle of the Wabash, when Walker surrendered with his followers, 132 in number, who were immediately disarmed and sent to the United States. Commodore Paulding acted on this occasion without specific instructions, and his arrest of Walker upon foreign soil was not fully approved by the executive. In Dec. 1860, Nicaragua presented him with a sword and also offered a tract of land (which latter, however, the U. S. senate did not allow him to receive), in testimony of her sense of the highly important service which he had rendered the republic. Commodore Paulding, while a lieutenant, published a volume entitled "Journal of a Cruise among the Islands of the Pacific" (New York, 1831).

PAULDING, James Kirke, an American author, born in Pleasant Valley, Dutchess co., N. Y., Aug. 22, 1779, died in Hyde Park, in the same county, April 6, 1860. His father, a descendant of a Dutch family originally established in Ulster co., cultivated a farm at the commencement of the revolution on the celebrated "neutral ground" of Westchester co. The depredations of tories and "cow boys" having compelled him to remove his family to a place of safety, he resided for several years in Pleasant Valley, but after the peace returned to Westchester co., where young Paulding passed his youth. His education was acquired partly at a neighboring village school and partly by a course of self-instruction, and about the commencement of the 19th century he removed to New York, where a great portion of his subsequent life was passed. Becoming intimate with Washington Irving, whose elder brother, William Irving, had married Paulding's sister, he published in connection with him a series of periodical essays of a humorous and satirical character, entitled "Salmagundi, or the Whim-Whams and Opinions of Lancelot Langstaff and others," with which the career of each author commenced. This literary partnership terminated with the appearance of the 20th number on Jan. 25, 1808; but neither Paulding nor Irving ever attempted to make a division of their contributions, and the whole is included in the stereotype editions of the works of the former. The success of "Salmagundi" encouraged Paulding to devote himself to literature, and about the commencement of the war between the United States and Great Britain he published successfully an allegorical satire entitled "The Diverting History of John Bull and Brother Jonathan." In 1813 appeared his "Lay of the Scottish Fiddle," a parody of Scott's "Lay of the Last Minstrel," which was reprinted in London. It was followed by the "United States and England" (1814), a pamphlet defending American institutions from the attacks of the London "Quarterly Review," which brought the author under the notice of President Madison, who appointed him secretary to the board of navy commissioners. A visit to Virginia in 1816 furnished the materials for his next work, "Letters from the South by a Northern Man" (1817); and in 1818 he published his longest and best poem, "The Backwoodsman," thoroughly American in scenery, incidents, and sentiment. In 1819 he produced a second series of "Salmagundi," written wholly by himself, and in 1822 "A Sketch of Old England by a New England Man," followed in 1824 by a similar work entitled "John Bull in America, or the New Munchausen," purporting to be an English cockney's account of his tour in the United States. In 1823 appeared his first novel, "Koningsmarke," followed by "Merry Tales of the three Wise Men of Gotham" (1826); "The Traveller's Guide" (1828), subsequently called "The New Pilgrim's Progress" in consequence of a whimsical mistake as to the character of its contents; "Tales of the Good Woman" (1829), and the "Book of St. Nicholas" (1836), which were chiefly of a satirical character. "The Dutchman's Fireside" (1831), a story of the "old French war," and commonly regarded as his best work of fiction, passed through 6 editions in the course of a year, was republished in London, and translated into the French and Dutch languages. His next novel, "Westward Ho!" (1832), the scene of which is laid principally in Kentucky, also met with great success. In 1835 he published a "Life of Washington" for youth, and in the succeeding year a work entitled "Slavery in the United States," in which he defended that institution on social, economical, and physiological principles. In 1837, having for a number of years previous held the position of navy agent for the port of New York, he was appointed by President Van Buren secretary of the navy. In 1841 he retired to a country seat at Hyde Park on the Hudson river, where the remainder of his life was passed. He wrote two more novels, "The Old Continental, or the Price of Liberty" (1846), and "The Puritan and his Daughter" (1849). He also published anonymously an illustrated volume of stories entitled "A Gift from Fairy Land" (1838), and in conjunction with his son, William Irving Paulding, a volume of "American Comedies" (1847).

PAULICIANS, a sect of eastern Christians whose origin is somewhat obscure. Photius supposes that the sect began in the 4th century, and was a variety of Manichaeism, and that it took its name from one Paul, the son of Callinice, who with his brother John was its founder. Another tradition refers the name to Paul the Armenian, a later teacher of the sect. The most probable theory is that which derives the name from the apostle Paul. The probable founder of the sect was Constantine, a Marcionite preacher of Mananalis, near Samosata on the Euphrates, who took the name of Sylvanus, as that of one of Paul's companions (Silas), and established the precedent, afterward closely followed by the brethren of the sect, of assuming the names of those who were friends of the great apostle. After 27 years of labor, Constantine was put to death for the cause he had espoused, which had already assumed the proportions of a formidable heresy. The officer Simeon, sent to put the heresy down, became a convert, took the name of Titus, assumed the leadership of the sect, and was in his turn, after 3 years of toil, burned at the stake. His successor was Paul, under whose sons, Timothy and Theodore, the sect was rent by schism, Timothy holding to the transmission of spiritual gifts by apostolic succession, which Theodore rejected. Timothy (whose proper name was Gegnaesius), having adroitly managed to evade in his answers the charges of heresy, was able to continue his preaching for 30 years. On his death another schism arose. The sect had gradually increased and diffused itself, until it was found not only in Syria and Armenia, but in the provinces of Asia Minor. About the beginning of the 9th century, the conversion of the Galatian Sergius by a Paulician woman gave new life to the sect. Under the new name of Tychicus, he preached as an evangelist with indefatigable zeal in every part of Asia Minor, imitating the apostle not only in his discourse, but in his manner of life. His enemies accused him of arrogating worship to himself as the Paraclete. The Paulicians were now driven beyond the territories of the empire to find protection from the Saracens, and reprisals were made, until Sergius, though he had protested against this return of evil for evil, was in 835 assassinated by a fanatic named Tzanio. In spite of this persecution, however, the sect continued to grow and spread. Under the empress Theodora a new expedition was sent to exterminate them from Armenia, and 100,000 victims perished in this persecution. In 969 the emperor John Zimisces transported a large number of the sect to Philippopolis in Thrace, whence they were able to extend themselves in Europe, not justifying by any change of faith the emperor's hope of their conversion. A similar attempt by Alexis Comnenus a century later had hardly better success. The sect continued to flourish under other names, and the principles of the Paulicians were perpetuated by the Euchites, the Bogomiles, the Cathari, the Waldenses, and to some extent by the English disciples of Wycliffe.—The Paulicians held that the evil spirit, born of darkness and fire, was the creator of the lower world; that the soul of man, originally related to God, had been made liable to sin by its union with the flesh; that all men are capable of recovery; that Christ came down from heaven, bringing with him a body of finer mould, with which he passed back to heaven when his work of redemption was finished; that the mother of Christ was not sinless or a proper object of worship; that the cross was properly a symbol of Christ's diffusive love, and not of the curse which he bore or of his vicarious suffering. They denied the validity of the sacraments, interpreted spiritually baptism and the Lord's supper, would not recognize any priestly dignity, and insisted both in the ritual and in the households of the church upon simplicity of customs. They rated highly the study of Scripture, and especially honored those who would multiply and expound its record. They made no scruple of using falsehood in dealing with other sects, and were ready to deny their faith when interest served.—The ancient authorities on the history of the Paulicians are Photius, and Peter of Sicily, ambassador to Armenia of the emperor Basil (868).

PAULUS, Heinrich Eberhard Gottlob, a German Protestant theologian, born in Leonberg, Würtemberg, Sept. 1, 1761, died in Heidelberg, Aug. 10, 1851. He studied the oriental languages and divinity at Tübingen and Göttingen, and made a voyage to England to examine the manuscript treasures in the libraries of London and Oxford. On his return home in 1789 he was appointed professor of oriental languages at Jena, which position he exchanged in 1794 for the chair of theology in the same university. In 1804 he became professor of theology at Würzburg, and in 1811 taught exegesis and philosophy at Heidelberg. Among his works are: *Philologisch-kritischer und historischer Commentar über das Neue Testament* (1800–'4); *Das Leben Jesu* (1828); and *Exegetisches Handbuch über die drei ersten Evangelien* (1830).

PAUPERISM. In every organized community there has existed a class of persons obtaining their subsistence, partially or wholly, from public relief. The best method of repressing pauperism has been one of the most important topics of consideration in the political economy of all organized governments. Solon made provision against pauperism in his Athenian code, directing that the state should adopt the widows and orphans of those who fell in battle, and support those who were wounded or disabled. "It is better," says the Roman code, "that vagabonds should be left to die of hunger, than that they should be supported in their begging." Mendicity was discouraged and prohibited by Charlemagne and his successors, while liberal provision was made for the sick and suffering poor.—In England, all enactments for the suppression of beggary having failed of effect, the effort was made to confine the beggar to his birthplace, or to the parish in which he had acquired a settlement. He was prohibited from leaving it without a certificate from the parish magistrate, and if he did so was to be whipped and sent back. In his own parish he might beg, though he was liable to be compelled to work. The act 43 Elizabeth, c. 2 (1601), was a great advance on the previous poor laws, and remained in force without material modification till 1834. It directed the overseers of the poor in each parish to take measures for employing the children of all parents who were thought unable to maintain their children, as well as all such persons as, having no means to maintain themselves, did not practise any trade or labor to earn a living. For this purpose, a tax on real and personal estate was to be levied, and all lame, blind, old, and impotent persons were to be provided for; children were to be put out as apprentices, and a sufficient stock of flax, hemp, wool, and other material provided to set the poor at work. Poorhouses were to be built by the church wardens and overseers, to accommodate the impotent poor only. Persons possessing means were to be assessed for the support of their poor kindred. In cases of bastardy, the putative father was compelled to pay a certain sum weekly to the mother, and in default of payment was imprisoned. The effect of this provision was to make the income of the unmarried mother, in many instances, greater than that of the honest wife and mother; and as the parish supported the illegitimate children, it actually offered a premium to licentiousness. Under these provisions, the expense of the support of paupers increased. In 1801 the expenditure for this purpose was £4,017,871; in 1818 it had risen to £7,870,801, nearly doubling in 17 years. For the 16 following years it ranged from £6,000,000 to £7,000,000. The population of England and Wales in 1818 was 11,575,000, and the rate of poor relief per head to the population 6*s.* 0¾*d.* But such was the aversion of the people to change, that, although several successive commissions from 1801 to 1828 recommended plans of legislation, no material change was made in the poor laws. In 1828 another commission was appointed, and continued their investigations for several years. Their report in 1832 included a new system of poor laws, which became a law in 1834. Retaining the best features of the act of 1601, it further provides for a central board of 3 commissioners for the general superintendence and control of all bodies charged with the management of funds for the relief of the poor. Subordinate to these are 9 district commissioners, and the whole are subject to the direction of the secretary of state for the home department. The commissioners are empowered to order workhouses to be erected or hired, enlarged or altered, with the consent of a majority of the board of guardians. They may unite a number of parishes in a poor law union, for the purpose of a more economical and effective administration, but in such a way that each parish shall defray the actual cost of the support of its own poor. The parishes composing a poor law union elect their board of guardians, without the consent of a majority of whom money cannot be raised for building purposes; but the masters of the workhouses, and other paid officers, are under the orders of the commissioners, and removable by them. No wages are paid to the poor out of the poor rates, and except in extraordinary cases relief is only given to the able-bodied poor and their families within the walls of the workhouse, where labor is required of them in return for it. The provisions in regard to illegitimate children are intended to materially check bastardy. The putative father, if prosecuted, is required to pay the sum fixed by law (2*s.* 6*d.* per week) to the union instead of the mother, and mother and child are received into the workhouse. The children of paupers are educated in workhouse schools. In two years after its passage this law had reduced the cost of the relief of the poor 40 per cent. A similar system has been introduced into Ireland. The following statistics show the diminished cost of the relief for the poor at periods 30 years apart. Table II. also gives some data for a comparison of the relief to the poor in London with that in Paris and New York.

TABLE I.—STATISTICS OF PAUPERISM IN ENGLAND AND WALES IN 1859.

Estimated population of England in 1859	19,578,000
Amount of poor rate levied in 1859	£8,108,224
Receipts from other sources in aid of poor rate (parochial funds, legacies, earnings of paupers, &c.)	326,563
	£8,434,788
Of this sum there was appropriated directly to the relief of paupers (exclusive of expenditures for salaries of commissioners, erection of buildings, providing for special classes of the afflicted poor, medical relief, &c.)	£5,558,689
The whole number of paupers in England and Wales in 1859 was	902,052
Percentage of population	4.6
Of these there were in the union workhouses	107,050
" " outdoor poor	692,384
In hospitals, asylums, dispensaries, &c.	102,618
The number of insane paupers was	19,487
The expenditure for the relief of the poor solely, per head of the population, was	5*s.* 8*d.*=$1.37
The medical relief of the poor cost	£230,597
Of the sum expended directly for relief, there was paid for maintenance	18.02 per cent.
Ditto, in outdoor relief	58.00 "
Ditto, for pauper insane in asylums	6.08 "
Ditto, for salaries, interest, &c.	22.18 "
No. of poor law unions in 1858-'9	618
No. of parishes comprised in them	14,484
No. of single parishes not included	181

In 1818, the population of England being estimated at 11,575,000, the amount expended for the relief of the poor was £7,870,801, or an excess over 1859 of £2,312,112, while the population had increased meantime 8,003,000.

TABLE II.—LONDON VOLUNTARY CHARITIES IN 1859.

92 hospitals having an income of		£300,000
12 societies for preservation of life and health, benefiting 89,000 persons		40,000
17 penitent refuges and reformatories		2,500
15 charities for relief of the destitute, benefiting 150,000 persons		25,000
14 charities for poor debtors, widows, strangers, &c.		30,000
4 Jewish charities, exclusive of 20 minor Jewish charities		10,000
19 provident societies		9,000
27 pension societies, benefiting 1,600 persons		58,968
83 trade societies of a purely charitable kind		113,467
Carried forward		£588,935
Brought forward		£588,935
126 asylums for the aged, benefiting 3,000 persons		87,690
9 charities for the deaf and dumb, the blind, &c.		25,000
21 educational societies		72,247
31 educational asylums, benefiting 1,777 persons		45,465
60 home missions, some extending their operations beyond the metropolis		400,000
5 miscellaneous charities		8,234
Total income		£1,222,529
Legal relief of the poor.		
In the workhouses	32,640	
Outdoor poor	73,500	
Whole number relieved	106,140	
Population of London in 1859	2,362,236	
Proportion of paupers to population	1 to 22.2	
Expenditure for poor relief solely		£867,337
Aggregate of voluntary and legal relief		£2,089,866

Or 17*s.* 8*d.*=$4.28 to each inhabitant.

—In France, workhouses were established for the able-bodied poor in 1612, by a decree of Maria de' Medici, and it was directed that all mendicants should be confined in them and set to work. In spite of the workhouses, however, beggary continued to increase. In the reign of Louis XIV. the Bicêtre was founded as a combined hospital, asylum, and almshouse. In 1693 a terrible famine occurred in France, when 25,000 of the poor in Paris were utterly destitute, and mendicancy was necessarily permitted. Having once regained its foothold, it continued to be one of the crying evils of the country for the next 100 years. In 1790 workhouses were again established, and mendicity sternly prohibited. The decree of March 19, 1793, took the ground that the assistance of the poor was a national debt, and divided the funds appropriated to their relief as follows: the assistance of labor to the healthy poor, in time of dearth of labor or of calamity; assistance (in money or provisions) at home to the infirm poor, their children, the old, and the sick; hospitals for the sick who had no homes, or could not be cared for there; foundling hospitals and asylums for abandoned infants, the old, and the homeless infirm; and aid for unforeseen accidents. Napoleon I. forbade mendicity by severe laws. Soon after the accession of Louis Philippe to the throne a thorough investigation of the whole subject of pauperism was instituted, and the code revised, the basis of all assistance to the poor being the principle of inciting them to self-support. There are now fewer mendicants in France than in any other country in Europe. The able-bodied or healthy poor are assisted, where assistance is necessary, either at their homes or in workhouses (*dépôts de la mendicité*); the sick and infirm poor are abundantly provided for in 1,324 hospitals, asylums, and hospital asylums; and foundlings, orphans, and abandoned children, in foundling hospitals and orphan asylums. Yet there is a steady increase of able-bodied paupers in a larger proportion than the increase of the population. This increase in 1853, as compared with the 5 preceding years, was $\frac{8}{100}$ of 1 per cent. On the other hand, the number of the sick and infirm is gradually decreasing, the diminution being 2.26 in every 1,000 inhabitants in 1858, as compared with the 5 preceding years; and the number of foundlings and abandoned children in 1858, as compared with the 17 years preceding, had diminished 58 per cent. The following tables show the amount and kinds of relief to the poor in France in 1858, the latest year for which full returns have been made public:

TABLE III.—STATISTICS OF PAUPERISM IN FRANCE IN 1858, WITH COMPARISON OF PREVIOUS YEARS.

I. *Assistance to the Healthy Poor.*

Average annual number assisted from 1848 to 1852	962,516
Number assisted in 1858	1,022,996
Amount expended for their relief in 1858	$3,420,585
Percentage of the whole amount furnished in food, 1848–'52	45.25
Ditto, 1858	56.32
Percentage in clothing, 1858	6.44
Percentage in fuel, 1858	4.63
Percentage in money, 1858	20.45
Percentage of assistance to whole population in 1848–'52	2.78
Ditto, 1858	2.86
Average amount of assistance per head in 1848–'52	$2.23
Ditto, 1858	2.83

II. *Assistance to the sick and infirm Poor, in Hospitals, Asylums, and Hospital Asylums.*

Total number of hospitals and asylums in France	1,824
Hospitals for the sick alone	885
Asylums for the aged and infirm, or disabled	289
Hospital asylums, for insane, blind, deaf-mutes, idiots, &c.	650
Number of beds in all these institutions	181,016
Average annual admissions from 1848 to 1852	616,207
Admissions in 1858	542,828
Admissions per 1,000 inhabitants in 1848–'52	17.82
Admissions per 1,000 inhabitants in 1858	15.06
Total expense for 1858	$18,431,879
Daily average expense for each inmate	15.4 cts. to 17.1 cts.
Weekly average expense for each inmate	$1.08 to $1.20
In 1,085 of these institutions there were in 1858:	
Males	285,188
Females	162,885
Adults	404,447
Children under 15 years	42,926
Deaths in the asylums and asylum hospitals in 1858	9,216, or 9.71 per ct.
In the hospitals for the same year	8.01 "

III. *Children assisted, in Foundling Hospitals, Orphan Asylums, &c.*

Average annual number of children in asylums, or abandoned by their parents, in 1848–'52	125,518
Number in 1858	129,176
Annual expense of their support in 1848–'52	$1,571,127
" " " " 1858	$1,842,536
Annual expense per head in 1848–'52	$15.90
Weekly expense in 1848–'52	$0.30.6
Annual expense per head in 1858	$18.21
Weekly expense in 1853	$0.35
Of the children in asylums, &c., in 1858, there were:	
Foundlings	72,472
Abandoned by their parents or relatives	25,842
Orphans	6,460
Temporarily assisted	24,402
Proportion of these children to 1,000 inhabitants in 1845–'52	7.58
Ditto, 1858	8.58
Proportion to 100 births in 1845–'52	2.78
" " " 1853	1.87
Percentage of deaths in 1845–'52	10.66
" " 1858	8.16
Percentage withdrawn or indentured in 1845–'52	10.85
" " " 1853	12.50

Summing up these statistics, we have:

Assistance to the healthy poor	$3,848,536
Hospitals, asylums, and asylum hospitals	18,431,482
Foundling hospitals, orphan asylums, &c.	1,842,536
To which should be added (estimated by the government) for foreign paupers	1,851,000
Aid and suppression of mendicancy	1,158,000
Civil list, aid to institutions, pensions to wounded soldiers, &c.	6,755,000
Total	$27,886,554

The mutual relief societies of France do much to benefit the poor and prevent pauperism. The members are almost exclusively from the laboring classes. In 1859 there were of these societies:

Approved by government	2,274	
Authorized "	1,851	—4,125
The number of members was		584,283
Of whom were honorary members		61,873
The amount of funds held by these societies was		$5,558,993
Their annual receipts were in round numbers		$2,316,000
The population of France in 1856 was		36,012,669

The following statistics relative to pauperism in Paris are of interest:

Population of Paris, 1851		996,067
No. of outdoor poor assisted in 1852		77,999
No. of illegitimate births, in a total of 33,284, in 1852		10,958
No. of beds in the hospitals of Paris in 1852:		
In hospitals proper	6,743	
In asylums, &c.	9,828	
In foundling hospitals	599	—17,170
Cost of support of the hospitals, asylums, and asylum hospitals in Paris in 1852		$1,264,422
Cost of workhouses (*dépôts de la mendicité*)		847,432
Assistance to foreign paupers		280,477
Pensions and assistance		80,476
Total		$2,422,807

—Italy, Spain, and Portugal have been overrun with beggars from time immemorial. Holland and Belgium, too, have during the present century at least been remarkable for the number of their paupers. In 1855 the former country had 280,000 poor receiving assistance, or 1 to every 12 inhabitants; and the expenditure for their relief was about $2,500,000, or 71.4 cts. to every inhabitant. The religious denomination to which the pauper belongs is expected to sustain him, and it is only when their means are exhausted that the government steps in with its aid. Aside from this government assistance, there were 2,884 societies for aiding the poor at their homes, of which 356 were in the towns, and 2,528 in the country. Belgium has the reputation of being the poorest country in Europe; a large proportion of its peasantry never taste meat, but subsist on vegetables and the black bread of the country. In 1846 it had 699,857 paupers, or 1 to 6.20 inhabitants. East and West Flanders were the poorest portion of the kingdom, having 400,000 paupers to 1,400,000 inhabitants, or 1 to 3.5 inhabitants. There has been considerable improvement since 1846, and a large number are now in the almshouses, workhouses, and reformatories, who were formerly mendicants. Throughout the states of Germany (with the single exception, we believe, of Bavaria) mendicity is strictly prohibited, and the pauper is remanded generally to the parish where he was born, which is liable for his support, and employs him in its workhouse, if he is able to labor. In Bavaria there is a privileged class of beggars. In several of the states there is a poor fund, derived from the confiscation of the convents at the time of the reformation. In Sweden, each commune or parish is charged with the support of its resident poor, and in many of the parishes the foundations, legacies, and gifts for the relief of the poor are so large as to require very little additional taxation. The abandoned pauper, or one who has acquired no residence, is compelled to enter the army or navy, or, if unfit for either, must labor on the public works, or in a house of correction. In Denmark, assistance is regarded as an advance made to the pauper, which he must repay by his labor. The parish clergyman, the local director of the police, and one or more notables or property holders, constitute the board to which all applications for relief must be made. There are legal provisions for the relief of parishes which are overburned with paupers. In Russia, paupers have been of two kinds, serfs and free. The masters are compelled to provide for all the needs of the pauper serf. The serfs on the crown lands, if sick, must be supported by their families, or, if they are unable, by the parish. The parishes in the crown lands have erected almshouses and hospitals, which are partially endowed. The emancipation of the serfs, now in progress, will necessitate changes in the poor laws. In Turkey, among the Mohammedans, almsgiving is considered as equally a duty with prayer; the pious Moslem devotes the tenth of his income to the poor, and all the mosques have treasuries for their benefit. Most of the sultans have endowed hospitals and asylums for the sick, the infirm, the unfortunate, the insane, and the blind.—In the United States, different systems of management are adopted in different portions of the country. In New England, the general features of the English law of 1601, though without its perversions, are preserved. The resident paupers are cared for in the parishes or towns in which they were born or have gained a settlement. Sometimes, where a family seem likely to become paupers, their taxes are remitted for a series of years by the town officers, to prevent their gaining a settlement. In the smaller towns the able-bodied paupers receive only temporary and occasional relief, while the infirm, aged, or demented are provided for at a poorhouse, or a contract is made for their support with some citizen, who in bidding for it takes into account his ability to exact some labor from them. In the larger towns the poorhouses or almshouses have usually some land attached to them, and often workrooms for other simple labor, where such as are able to work are employed. Occasional and temporary assistance is also rendered to the outdoor poor at their homes, usually either in food or fuel, though sometimes in clothing and small sums of money. There are beside, in all the larger towns, beneficent societies, widows' societies, and orphan asylums, which aid in the relief of the poor; and the religious denominations to some extent provide for their own poor members. There are state almshouses for foreign paupers, or for those who, from any cause, have not gained a settlement. Table IV. gives the pauper statistics of Massachusetts for the years 1858 and 1859, which furnish a fair example of the New England system.

TABLE IV.—PAUPERISM IN MASSACHUSETTS.

	1858.	1859.
Number of almshouses	212	222
Acres of land appertaining to almshouses	21,296	21,601
Estimated value of almshouses and lands	$1,270,028	$1,300,671
Number of persons relieved in almshouses	11,845	10,369
Average number supported in almshouses	3,254	....
Average weekly cost of support of each pauper in the almshouses	$1.57	$1.47
Number of invalid poor in almshouses	2,283	1,980
Estimated value of pauper labor in the almshouses	$31,849	$21,060
Outdoor poor	23,071	21,954
Weekly average cost of outdoor poor per head	$1.10	$1.04
Number of paupers of foreign birth	12,440	....
Number who had gained a settlement in the state	14,016	11,783
Number of insane paupers	870	816
Number of idiotic paupers	306	326
Paupers in consequence of intemperance	13,885	17,809
Whole number of paupers in the state, exclusive of those in state almshouses	37,206	31,400
Net expenditure for the support of paupers	$550,620	$522,813
Indigent children under 14 years of age supported at public expense	....	1,892
In the State Almshouses, and Hospital at Rainsford's Island.		
Number at beginning of the year	2,240	2,037
Received during the year	7,616	5,831
Whole number	9,856	7,868
Discharged	7,095	5,651
Died	707	493
Average cost per head, per week, in the almshouses	$1.01	$1.00
Ditto at Rainsford's island	....	$2.49
Expenditure for support of these institutions	$170,604	$181,418
For state paupers not in almshouses	....	$82,519
Total expenditure of the state and towns for paupers	$720,624	$786,245
Population of Massachusetts in 1860	1,231,494	1,231,494
Rate per head of population of the expenditure for paupers	$0.58.5	$0.63.8

In New York, Pennsylvania, Ohio, and most of the older western and middle states, care of the poor devolves upon county officers. Each county has its almshouse, its workhouse, and its gaol, and the more populous ones often also an insane hospital. In these institutions the feeble and infirm or insane pauper is cared for, and the able-bodied compelled to work, usually on the county farm, which commonly consists of from 100 to 200 acres of land. The amount of labor accomplished is but little, and does not materially lessen the cost of support of the paupers. There is also provision for rendering temporary and occasional assistance to the outdoor poor. In New York, as the great receiving port of foreign immigration, a board of commissioners of emigration has been appointed by the state, who levy a tax of $2 on each immigrant arriving at the port, or require bonds from the owners of the immigrant ships that they shall not become chargeable to the state within 5 years. These commissioners have established on Ward's island, New York, a hospital, refuge, insane hospital, &c., where the foreign paupers arriving there are maintained till the 5 years are completed, when, if they still continue paupers, they are turned over to the state authorities. The commissioners of emigration are also liable for the maintenance of any for-

TABLE VI.—STATISTICS OF PAUPERISM IN THE CITY AND COUNTY OF NEW YORK FOR THE YEAR 1860.

Name of institution or department affording relief.	No. in charge, Jan. 1, 1860.	No. received during the year.	No. remaining Jan. 1, 1861.	Whole No. relieved during the year.	Males.	Females.	Children.	Natives.	Foreigners.	Whole amount of relief.	Cost per head per week.	Relief rendered in food.	Relief rendered in clothing.	Relief rendered in fuel, &c.	Relief rendered in medicine and medical attendance.	Relief rendered in money.	No. of deaths.	No. of births.	No. of insane and idiotic.

Ratio per head of population of the expenditure for the poor in New York city.........................	$0.77.6	$0.66.6
Population of New York state except Albany co. in 1860................	8,735,607	8,735,607
Ratio per head of population of the expenditure for the poor in the entire state, except Albany co........	$0.56.6	$0.50.2

In the city of New York, the charge of the poor and of criminals is in the hands of a board of 4 commissioners of charities and corrections, under whose care are the Bellevue hospital, in the city; the almshouses, workhouses, insane asylum, island hospital, small pox hospital, and penitentiary, on Blackwell's island; 4 city prisons on New York island; the Randall's island nursery, and the nursery hospital, on Randall's island; and the city cemetery, on Ward's island; the charge of the outdoor poor and partially of the colored home and colored orphan asylum. There are also in the city a great number of societies and institutions having for their object the relief of the poor, or of particular classes of them. We have endeavored to bring the statistics of these together, so as to exhibit at one view the public charities of the city. (See table VI. on the preceding page.) It will be observed that a large majority of those receiving relief are either of foreign birth or but one remove from it. Yet notwithstanding this very large foreign element, exceeding, according to the best authorities, 75 per cent. of the whole number of paupers, the cost for the support and relief of the poor is in proportion to the population less than half in the state, and even in the city of New York but about half, that of England. In the slaveholding states, the obligation of the master to support the aged, sick, feeble, infirm, or mentally disordered slave, has obviated to a considerable degree the necessity of pauper laws. The state government, or the county authorities, in case of general loss of bread crops, appropriate a specified sum, to be raised by tax, and apportioned to the poor either in money or breadstuffs. In the new states, the poor laws are not in all cases fully digested and in successful operation, but they are generally on the model of those of New York and Ohio.—See Dr. R. Burn, "The History of the Poor Laws" (8vo., London, 1764); Sir F. M. Eden, "The State of the Poor, or History of the Laboring Classes in England from the Conquest" (8 vols. 4to., London, 1797); Sir George Nicholl, "Histories of the English, Scotch, and Irish Poor Laws" (4 vols., London, 1854–'6); Stephen Colwell, "Themes for the Protestant Clergy, by a Layman" (Philadelphia, 1855); C. de Brouckère, *La charité et l'assistance publique* (Brussels); H. A. Frégier, *Des classes dangereuses de la population dans les grandes villes* (2 vols. 8vo., Paris, 1840); Christophe Moreau, *Du problème de la misère et de sa solution* (8 vols. 8vo., Paris, 1851).

PAUSANIAS, a Spartan general, son of Cleombrotus and nephew of Leonidas, belonging to the Agid branch of the royal family. He succeeded his father as guardian of the young king Plistarchus, the son of Leonidas, which office he retained until his death. He first comes into notice as leader of the combined forces of the Greeks in the great battle at Platæa against the Persians under Mardonius in 479 B. C. The successful result of the battle gave him so high a reputation, that in 478 he was chosen commander of the fleet destined to act against the Persians. The armament first sailed against Cyprus, and restored to freedom most of the cities of that island, and then turning to the Thracian Bosporus reduced Byzantium. The natural insolence of Pausanias now became conspicuous. After the battle of Platæa he had besieged Thebes, and having obtained possession of Timagenidas, a leader of the Medizing faction, had carried him to Corinth and put him to death without trial. In the tripod dedicated at Delphi by the victorious Greeks, he styled himself alone as the leader of the Greeks and destroyer of the Persians; which inscription was subsequently erased by the Lacedæmonians themselves, who substituted in place of his name the names of the confederate nations engaged in the battle. Upon the capture of Byzantium he connived at the escape of the Persian prisoners, who carried a letter to Xerxes, offering to bring under his dominion Sparta and the rest of Greece, and demanding in return the hand of his daughter in marriage, and that a confidential person should be sent to the seaboard, through whom to correspond. The Persian monarch acceded to these propositions, promising to furnish as much money and as many men as would be needed, and sending Artabazus down to treat with him. Pausanias now became more arrogant than ever. He assumed the Persian dress, imitated the luxurious conduct of the Persian chiefs, and journeyed through Thrace with a body of Persian and Egyptian guards. His treasonable course at length came to the ears of the Spartans, and he was recalled; but although put upon trial, there was no evidence sufficient to convict him of treachery. Under pretence of taking part in the war, he now sailed to Byzantium, and, resuming his correspondence with Artabazus, so conducted himself that the Athenians expelled him from the city. He then retired to Colonnæ in Troas, where he continued his communications with the Persians, until he received a peremptory order from Sparta to return. Upon his arrival he was immediately imprisoned, but soon released on his demand for trial, in which he trusted to clear himself by the use of money. Much was suspected, but inasmuch as nothing serious could be proved, he remained at liberty and prosecuted his designs, and to carry them out tampered with the helots, to whom he offered freedom and the rights of citizenship. Although some of the helots themselves divulged the plot, the ephors feared to take decisive measures against a man of his position. At length an Argilian slave, who was intrusted with a letter to Artabazus, noticing that none of the previous messengers had come back, broke the seal and discovered that he was to be put to death. He immediately showed the letter to the ephors, and by their direction took refuge in the temple of Neptune at Tænarus, where two of the ephors hid themselves. There they heard the conversation of Pausanias with his slave, which left no doubt of his guilt. As he was about to be arrested in the street, he fled to the temple of Athena Chalciœcus, where he was walled in, his own mother being said to have laid one of the first stones for this purpose. He was carried out as he was dying to save the temple from pollution. The date of his death is later than 471 B. C. He left 3 sons, of whom Plistoanax became one of the kings of Sparta.

PAUSANIAS, a Greek topographer, supposed to have been born in Lydia. Nothing is known of his life except what he himself tells us, and from him we learn that he was engaged on a part of his work in the time of Antoninus Pius, who died A. D. 161, and wrote his 8th book during the latter part of the reign of Marcus Aurelius, which closed in 180. His work is entitled Της ʽΕλλαδος Περιηγησις, "Itinerary of Greece," which is divided into 10 books, and comprises descriptions of the whole of Peloponnesus and of the most interesting parts of Hellas proper. The minuteness and completeness of his descriptions prove that he must have visited personally all or nearly all the places which he describes, and it is also probable that he had visited the islands of the Ægean, Rome, Palestine, and other parts of Syria. His books are chiefly taken up with descriptions of antiquities, statues, pictures, and public edifices, and the physical peculiarities of the countries in which he travelled. All the mythological tales connected with these are narrated. The general fidelity of his topographical description has been thoroughly tested by modern authors. The first edition of his work, which was exceedingly incorrect, was printed by Aldus at Venice (fol., 1516). Since then there have been several, of which the latest are those of J. H. C. Schubart and C. Walz (3 vols. 8vo., Leipsic, 1838–'40), and of Dindorf (Paris, 1845). The "Itinerary" was translated into English by Thomas Taylor (3 vols. 8vo., London, 1793–'4).

PAUSIAS, a Greek painter, a native and resident of Sicyon, who flourished between 360 and 330 B. C. He was instructed by Pamphilus, and was a contemporary of Aristides, Melanthius, and Apelles. Pliny says that he was particularly distinguished as a painter in encaustic with the *cestrum*, and he is believed to have been the first to decorate the ceilings and walls of houses in this style. He was fond of painting small pictures of boys, and from his intimacy with Glycera, a flower girl, whose portrait by him is highly extolled by Pliny, he acquired great skill in flower painting. Another celebrated painting by him, representing a sacrifice, and remarkable for the foreshortening of the victim and the strong relief of the surrounding figures, was preserved in the portico of Pompey at Rome. This style of painting is said to have originated with Pausias. The greater part of his paintings were probably transported to Rome when Sicyon was obliged, in order to pay her debts, to part with all her art treasures which were public property.

PAUW, CORNELIUS DE, sometimes called NICOLAS, a Dutch historical writer, born in Amsterdam in 1739, died in Xanten in 1799. He was educated at Göttingen, and obtained through the influence of his brother-in-law, the father of the revolutionist Anacharsis Clootz, the office of canon of Xanten, in the duchy of Cleves. Subsequently he was made reader to Frederic II. of Prussia. He wrote several works in French, one of which was *Recherches sur les Américains* (8vo., Berlin, 1770 and 1772), designed to prove "the native inferiority of the savage Americans." In the parts relating to Paraguay he bitterly assailed the Jesuits, and his attacks on them made him unpopular with the Catholic clergy. Another work, *Recherches sur les Égyptiens et les Chinois* (2 vols. 8vo., Berlin, 1774; translated into English by Capt. J. Thomson, 2 vols. 8vo., London, 1795), was designed to prove "that no two nations ever resembled each other less than the Egyptians and the Chinese." In this treatise he observes that both nations were condemned "to an eternal mediocrity." His *Recherches sur les Grecs* (2 vols. 8vo., Berlin, 1787) was translated into English (London, 1793). In consequence of the invasion of the duchy of Cleves by the French revolutionary army, Pauw became subject to melancholy, and burned his *Recherches sur les Germains*, which was never published. Although a man of great learning and ability, he was exceedingly dogmatic in all his writings.

PAVEMENT (Lat. *pavimentum*, from *pavio*, to beat or ram down), a hard covering of stone, iron, wood, brick, cement, or asphaltum and sand for roads, walks, and floors of houses. As stated by Beckmann, the earliest mention of paved highways is of those prepared by Semiramis, according to the inscription which she set up, recorded by Valerius Maximus, lib. iii. cap. 7. Isidorus states that the Carthaginians had the first paved roads. The streets of Rome were not paved in the time of its kings; but the Appian way was constructed by Appius Claudius 193 years after their expulsion; and many of the streets are known to have been paved with stone in the 4th and 5th centuries after the building of the city. Pavements of blocks of lava worn into ruts by the wheels of carriages are met with in Herculaneum and Pompeii. From the descriptions of pavements given by Vitruvius, together with the poem of Statius on the Via Domitiana and the fragments of ancient paving still remaining, a very clear idea may be formed of the care given by the Romans to the construction of their famous roads. These were laid out with a width of from 8 to 15 feet by excavating a shallow trench along each side. The space between these was then dug down to a solid bed, or if this could not be reached piles were driven, upon which the materials of the road might be supported. The lowest course was of broken stones, none smaller than the fist; over these was a course 9 inches thick of rubble work, or broken stones cemented with lime, well rammed; over this was a course 6 inches thick of finer materials, chiefly broken bricks and pieces of pottery, also cemented with lime; and upon this was laid the *pavimentum*, which consisted of large polygonal blocks of the hardest silicious stones, sometimes of basaltic lava, of irregular form and nicely fitted together in a sort of mosaic. In the cities the slabs of stone were sometimes of rectangular form and of softer material, as in the forum of Trajan, which was paved with travertine. In every instance great care was taken to fit the stones to each other so as to produce a perfectly even surface. Stones corresponding to curb stones were sometimes set up to sustain a narrow gravel walk on each side of the road, and some of these were raised so as to serve for mounting blocks for travellers on horseback. The Romans continued to give great attention to the maintenance of the public ways in the city and of the military roads, many of which were constructed with immense labor through hills and masses of rock, and, by bridges and embankments, through swamps and across ravines and rivers. The floors of Roman houses were paved with pieces of bricks, tiles, stones, &c.; sometimes with tiles ground to powder and mixed in with mortar; and again with pieces of marble imbedded in a cement ground, and well beaten or rammed down, whence the name *pavimentum*. Mosaic pavements were first made in the time of Sylla, by whom, according to Pliny, one was constructed in the temple of Fortune at Præneste. They became very common in the houses of Pompeii, and were there produced with great taste in a variety of beautiful patterns, in marble of different colors, in tiles, and even glass, set in a fine cement and laid upon a deep bed of mortar. Some of the designs were of figures and scenes in actual life, being really pictures in mosaic. An account was presented to the British association in 1850, by Prof. Buckman, of an ancient Roman pavement discovered at Cirencester, in which appeared a medallion of Flora with a head dress and flowers of verdigris green when first uncovered. This being scraped off, the portion of the pavement beneath was found to be a beautiful ruby glass, the color of which was derived from peroxide of copper, and this by decomposition had become converted externally into the green carbonate of copper.—Though the paved roads of the ancient Romans surpass all other structures of the kind that have been made by civilized nations since their time, there are found in Peru remains of works of a similar kind of unknown age, and exceeding them in grandeur and extent. Such were the great roads from Quito to Cuzco, and continued south toward Chili, laid out through mountainous and almost impassable regions for distances variously estimated from 1,500 to 2,000 m., and about 20 feet in breadth. "They were built of heavy flags of freestone, and in some parts at least covered with a bituminous cement, which time has made harder than the stone itself." (Prescott, "Conquest of Peru," vol. i. p. 63.) In Central America, among the ruins of Palenque, are also found pavements of large square blocks of stone constructed with great skill and nicety.—In Europe during the middle ages comparatively little attention was given to the paving of streets and roads. Cordova in Spain was paved in 850 by Abderrahman II., the 4th caliph. Streets in Paris were first paved in 1184 by Philip Augustus. The improvement extended over the "Cross of Paris," as it was called—two principal streets crossing each other at right angles. In 1832, in excavating for a sewer in the rue St. Denis, this ancient pavement was met with about 8 inches below the surface. It consisted of blocks of stone about 4 inches long and 7 thick. A few inches below this was found the still more ancient roadway of gravel of the period of the Roman emperors. Many of the streets of Lon don were in a perilous condition by reason of deep pits and sloughs even as late as the 16th and 17th centuries. Holborn was paved by royal command in 1417; but the great market of Smithfield remained without pavement 200 years longer.—In modern times various methods and materials of paving have been employed. In Holland all the streets are paved with bricks, and these are also used for the same purpose in Venice. They obviously lack the strength and durability required for the passage over them of heavy loads. In other cities, instead of the broad flat stones used by the Romans, rounded pebbles of a few inches diameter, called cobble stones, found among the gravel of the diluvium or along sea and river beaches, have been very generally used. These, when of hard stone, closely set, and well rammed down in a bed of gravel or sand, form an economical and very durable pavement, one which gives secure footing to horses and is easily repaired. It is objectionable on account of the rattling noise of the vehicles drawn over it; and in the great thoroughfares of large cities, it has been found almost essential to substitute for it a pavement of rectangular blocks of granite, trap, or other hard rock. Blocks of wood have been at times in some repute, but they have proved objectionable on account of soon becoming slippery, particularly when wet, and also of their tendency to decay. They were commonly cut in hexagonal prisms and set upright, so that the wear came across the ends of the grain. Hemlock, being a cheap wood, was generally selected for the purpose. This pavement is not now, however, in use, and wood was quite given up in America and in Europe, when a new method of applying it was introduced into Boston in 1848 by Mr. Samuel Nicholson. He laid a pavement of spruce blocks, 3 inches square, in alternate lengths of 8 and 4 inches, so as to form a checkered surface, a depression of 4 inches lying at each side of each of the taller blocks. These depressions were then filled up to the level of the top of the long blocks with coarse pebbles or small fragments of stone. After being rammed, boiling pine tar was poured over the whole surface, which penetrated the loose materials and the substance of the wood also. A layer of sand about an inch deep was then spread over the surface and rammed. He also laid the 8 inch blocks in rows close together, interposing between each row a strip of inch board, 4 inches high; and in the space of one inch thus made between each row of blocks, the same application of fragments of stone, tar, and sand was made as before. In some instances the blocks were treenailed or pinned together; but this was not considered important, particularly if a flooring of boards was laid upon the foundation of concrete of coal tar, lime, and sand, which in all cases was prepared for the blocks. The specimens of pavement thus prepared continued in use for 7 years, upon a road over which heavy loads were constantly passing, without requiring any repair. The pavement has since been laid in other streets in Boston, and also in Chicago and other cities of the United States; and it is highly recommended for its durability, the secure footing it affords to horses, and its freedom from noise. On account of its keeping long in good repair, it is regarded as not comparatively an expensive pavement. Mr. Nicholson found its cost in Boston was sometimes a little under and sometimes a little over $2 per square yard, allowing nothing for the patent right. At the West it is found better to use hard wood instead of hemlock, pine, or spruce, though no doubt at increased cost. The wood may also be advantageously protected from decay by kyanizing or by the application of the solution of chloride of zinc. In use it is found that the fibres become slightly opened at the surface by the blows from the feet of the horses, and the sand ground in by these and the pressure of the wheels contributes not a little to the preservation of the wood. The foundation of concrete laid upon and covered by coal tar forms an impervious covering to the soil, protecting the atmosphere from unwholesome emanations. A pavement not much unlike the Nicholson pavement has been introduced into London, and is very highly recommended in a report made to the commissioners of the Holborn board of works, May 10, 1858, by Mr. Braithwaite, who pronounces it superior to every other paving material that has come under his notice. It is made of alternate rows of creosoted wood and broken granite cemented together with asphaltum. ("Mechanics' Magazine," vol. lxviii., p. 584, London, 1858.)—The result of a great number of experiments in paving in New York is the selection of what is called the Belgian pavement, as combining in the highest degree the advantages of economy in construction, durability, and a secure footing for horses. It is formed of blocks of a bluish trap rock made slightly pyramidal in form, which are placed with the base of the pyramid upward, exposing a face of 4 to 6 inches in each direction. The stone is found in great abundance along the Hudson river opposite New York, the formation being the same with that of the Palisades which appear further up the river. It is remarkably well adapted on account of its extreme toughness and hardness to resist wear, and it presents always a sufficiently rough surface to prevent horses from slipping. The streets of Naples are said to be paved with stone of this character, and notwithstanding the continuous use of the pavement for 1,000 years it has hardly been worn one inch in depth. The cost of this pavement in New York is from $1.86 to $2.50 per square yard. In this respect it is much to be preferred to the "Russ pavement," with which Broadway has been covered at an expense of not less than $6 per square yard. This is of cubical blocks of hard greenstone from Staten island or of trap from New Jersey, of about one foot square. In use it has been found that blocks of this size wear smooth, causing horses frequently to slip and fall; and much expense has already been incurred in either removing the blocks and substituting others of smaller size, or in grooving them upon the surface. In laying the stones, the first requisite is to obtain a good foundation; and in situations where the ground is not springy, all that is necessary is, after the removal of the superficial earth, to spread upon the natural bed beneath either a layer of dry sand, or first a layer of broken stones, which should be well rammed, and upon this the stratum of sand in which the paving stones are to be imbedded. In some instances the foundation is prepared with a bed of concrete, upon which the pavement is laid; and in France the most durable pavements are made by covering the old with sand and gravel in which the new stones are bedded. It is important to remove all earthy matters which could be converted into mud by infiltration of water; for its freezing and thawing would inevitably lift the stones, and destroy the pavement. Whenever a stone from any cause is depressed below the level of the adjoining stones, it receives heavier shocks from the wheels which pass over it, and its displacement goes on with accelerated velocity. The bed therefore must be uniformly solid, and the stones uniformly hard, and set together as closely as possible. Over the whole when finished sufficient sand is spread to fill all the interstices, into which it soon finds its way. An arched form is given to the paved floor, the sides abutting against the gutter and curb stones, which should be sufficiently deep or well backed to prevent any spreading. In using rectangular blocks, they are laid in courses running diagonally across the street for the purpose of preventing the formation of ruts, which might soon appear along the edges of stones lying in longitudinal courses. The duration of stone pavements varies greatly according to the materials employed and modes of construction. In the most frequented streets of Paris good pavements have been renewed as often as once in 6 years, and others badly constructed once in 3 years; but where the amount of travel is not very great, the pavement has lasted 20 years without renewal. The material largely used in Paris for paving is a somewhat friable sandstone from Fontainebleau. This is hardened by immersing it in liquid bitumen, and it is thus rendered much more durable, while the pavement is also made more compact and impervious to water.—Blocks of cast iron have been tried with considerable success both in England and in American cities. Various forms have been given to them with the view of securing the greatest strength and diffusing the weight over the largest surface. They are made rough on the upper side by grooves or short projecting points, so that they afford a firm footing to horses. But for the expense of this pavement, it would probably be preferred to any other.—For stables, gardens, and footwalks, the English have employed caoutchouc to some extent. The court of entrance of Windsor castle, and the stables of the dock yard at Woolwich, are thus paved.

PAVIA, a N. province of the kingdom of Italy, comprising the former Lombard province of Pavia and the Piedmontese districts of Bobbio, Lomellina, and Voghera; area, 1,290 sq. m.; pop. in 1858, 410,146. It is watered by the Po, the Ticino, and the Olona, and the canals of Bereguardo and Pavia and the Naviglio Grande pass through its boundaries. The country is generally level, and the soil fertile. Much attention is paid to the raising of silk and the breeding of cattle, and much of the cheese called Parmesan is made here. The climate is not very healthy. By the peace of Villafranca, July 11, 1859, Pavia, along with the other provinces of Lombardy, was ceded to France, and by that power transferred to Sardinia.—The capital, PAVIA (anc. *Ticinum*), is situated on an eminence on the left bank of the Ticino, not far from the spot where that river falls into the Po, and 19 m. S. S. W. from Milan; pop. 25,006. It is about 1 m. in extent each way, and is surrounded by an old wall. A communication with the suburb on the other side of the river is made by a covered bridge of 8 arches built in 1351. From this bridge the principal thoroughfare, called the Strada Nuova or Corso, extends through the city. Pavia was at one time remarkable for the magnificence of its buildings, and for its numerous lofty square towers, designed for ornament, or used as prisons or strongholds, whence it was called "the city of a hundred towers." Of the edifices now remaining, one of the most noteworthy is the cathedral, begun in 1488 and still unfinished, in a side chapel of which is the magnificent tomb of St. Augustine. The church of San Michele, a Lombard building 189 feet long by 81 feet wide, was finished during the 7th century. Santa Maria del Carmine, an immense Italian Gothic church built in 1373, is a remarkable specimen of the finest brickwork; and the church of San Francesco is of the same style and material. The celebrated church of San Pietro in Cielo d'Oro, which contained the tomb of Boëthius, is now mostly in ruins, the portion in good preservation being used as a storehouse. Of the few towers remaining, those of Belcredi and Maino are most deserving of mention, each being about 190 feet high. About 4 m. N. of the city is the most magnificent monastery in the world, the Certosa of Pavia, founded in 1396 by Giovanni Galeazzo Visconti, the first duke of Milan. The university of Pavia is the most ancient in Italy, and is said to have been founded by Charlemagne in 774; but it received its greatest impulse from the patronage of Galeazzo Visconti. It has a library of about 50,000 volumes, a collection of coins, a museum of anatomical preparations and of specimens of natural history, and a botanic garden instituted by the French; and there is also attached a school of the fine arts.

Of the two colleges now belonging to the university, the Collegio Borromeo educates about 40 students, and the Collegio Ghislieri about 60. The professors receive salaries varying from $600 to $1,200 per annum. Among the distinguished men who have been instructors here may be mentioned Vesalius, Cardan, Spallanzani, Volta, Scarfa, and Tamburini. In 1858-'4 the number of professors belonging to the university was 85, the number of assistants 21, and the number of pupils 1,423. Pavia is a bishop's see, and contains a theatre, a gymnasium, 2 hospitals, and charitable institutions. —Although at the end of the Roman republic Ticinum was a place of considerable importance, it is mentioned first by the geographers and historians of the empire. In A. D. 452 it was taken by Attila; but Theodoric, king of the Ostrogoths, rebuilt and fortified it, and erected a palace. During the Gothic wars it was the principal stronghold of that people in northern Italy, and there the royal treasury and valuables were kept; and so well fortified had it been, that during the Lombard invasion it resisted for 3 years a siege by Alboin. Taken by him in 570, the Lombard monarchs chose it for their residence, and it remained the capital of their kingdom until 774, when Desiderius, the last Lombard king, after a siege of 15 months, was obliged to submit to Charlemagne. Before this time it had begun to be called Papia, probably from the fact that Ticinum when it became a municipal town was enrolled in the Papian tribe. During the middle ages, the city underwent many vicissitudes; it was at one time an independent republic, at another ruled over by tyrants, and again subject to the authority of the Viscontis of Milan. It is chiefly memorable in modern history for the battle fought under its walls Feb. 24, 1525, between the French under Francis I. and the imperialists under Marshal Lannoy, in which the former were defeated and nearly destroyed, and their king taken prisoner. In 1527 and 1528 Pavia was twice taken by the French and laid waste. In 1796 it was stormed and pillaged by Napoleon, after an insurrection in which his garrison had been expelled. It came by the peace of 1814 into the possession of Austria, and so remained until 1859.

PAWN, a word undoubtedly derived from the Latin *pignus*, and meaning any article of personal property given in pledge, or by way of security for the payment of a debt, or the discharge of an obligation. The word is also used as a verb, and signifies to give such article in pawn or in pledge. It is a bailment, because the essence of the transaction is the delivery of the pawn by the pawnor to the pawnee. The first question that arises is, therefore: In what class of bailments is a pawn to be placed, in reference to the obligations of care on the part of the bailee? The answer is obvious; the bailment of pawn is a bailment for the benefit of both parties. The pawnor obtains credit or delay or other indulgence, and the pawnee obtains security. Therefore the bailee (or pawnee) is bound only to ordinary care, that is, not to the extreme care to which he would be bound if the benefit were all his own; but it is not enough if he takes the slight care of it which would discharge his duty and shield him from responsibility if the benefit were all the bailor's, the bailee himself deriving none from the transaction. Hence a pawnee is answerable for the loss of the pawn or for injury to it, only when there has been an absence on his part of ordinary care, which the law defines as that care which a man of ordinary prudence would take of his own property of like kind and under similar circumstances. If therefore the pledge be lost by some intrinsic defect, the operation of which might possibly have been prevented, or by some casualty which might possibly have been avoided, or by a superior force or violence which might have been resisted, the pawnee is nevertheless not responsible, unless he was wanting in the ordinary care above described.—A pawnee has a property in the pledge, but it is special, not absolute. It is sufficient to maintain an action against a third party for injury to or abduction of the pledge; and a judgment in such an action, when brought either by the pawnor or the pawnee, would be a bar to another action brought by the other.—A pawnee has only a right to hold the pledge; therefore, if he uses it, he does so at his own peril; and if the thing be lost or injured during such use, the pawnee is responsible, although the loss occurs wholly without neglect on his part. So, too, if he derive a profit from this use, he must account for this use of it unless the use was equally for the benefit of the pawnor. Thus, if the pawn be a horse, the pawnee may use it enough to preserve the health of the horse, and for this use make no compensation; but if he take a journey with the horse, he must allow the usual price. In all cases, the pawnee must account for income or profits derived from the pledge; and if he is put to extraordinary expense or trouble for the benefit of the pledge, or to preserve its value, although this would be for his own benefit also, he may charge the owner and pawnor for all this, unless there be a bargain to the contrary express or implied.—From what has been said it will be seen that if the pledge be stolen, the pawnee is not liable unless there was neglect on his part; but the question is at once important and difficult, as to the legal presumption of neglect or care. By the civil law, the presumption was against the pawnee; that is, if the pledge were stolen from him, he was responsible unless he could prove that there had been no neglect on his part. There are reasons for supposing that the law of England and of the United States is otherwise; and that if a pawnee can prove that the pledge was stolen from him, this will make it the loss of the owner, unless the owner can prove neglect or default on the part of the pawnee.—The distinction between a mortgage and a pledge has not been regarded as of much moment, nor has it been sharply defined, until of late; but recent adjudications, especially in New York, have given to it very great importance. Nothing is more common now than the giving of personal property, and especially of choses in action, as promissory notes, and of stock or scrip of incorporated companies, by way of security for loans or debts. Now this giving of security may be regarded as a mortgage or as a pledge. But if it be a mortgage, the parties acquire one set of rights, and come under one set of obligations; and if it be not a mortgage, but a pledge, their rights and their obligations are very different. The reason of this is, that it is of the essence of a pledge, that the thing pledged should pass at once into the possession of the pawnee, the property in the thing remaining in the pawnor. But if it be a mortgage, the property in the thing passes at once to the mortgagee, while the possession may and often does remain with the mortgageor. By property, in law, we mean what no other word expresses precisely, and none perhaps so nearly as ownership; the above rule therefore, if put into less technical phrase, might be expressed thus. A pawnor retains the ownership of the pledge, but places it in the possession of the pawnee as his security. But a mortgageor transfers at once the ownership of the property, retaining only a right to annul and defeat this transfer by payment of a certain debt. (See Mortgage.) Now the practical effect of this difference, which gives to it its importance, is this. A mortgagee, who acquires the property in or the ownership of the thing mortgaged, may do with that thing whatever he may do with his own. He may sell it, or mortgage it, or keep it in his own hands, always subject however to the mortgageor's right to redeem it; and it makes no difference to the mortgageor whether, when he comes to pay the debt and redeem the thing mortgaged, he finds it in one hand or another. But as a pawnee acquires no ownership whatever, he cannot sell the thing pawned, nor pledge it over, nor transfer it in any way. His whole right consists in the right of possession. He may keep the pawn as a security for his debt, because the owner has lost, not the right of property, but the right of possession; but the pawnee can do nothing else with it. Nor is this all; for he not only may, but must keep the pawn in his possession. This is his bargain with the pawnor by construction of law; and he holds the pawn only on this condition. If therefore the pawnee, for any reason or in any way, voluntarily parts with the possession of the pawn by transferring it to a third person, his lien or right of possession is at once gone; the pawnor at once recovers his right of possession, and may demand and repossess himself of the pawn, although the debt to secure which it was given remains wholly unpaid. The custom of brokers and others, who lend money or give other accommodation on the security of pledged stocks, has been the reverse of this. One holding such stock by way of security has regarded himself only as bound to have that stock ready to be returned when the debt is paid, and in the mean time he does what he pleases with it; that is, he sells it, or transfers it by way of pledge, or makes use of it as of his own. But recent decisions in New York have declared that by such use the right of the pledgee to hold the stock is wholly lost. The pledger may therefore demand it at once, although his debt be not paid; and if it be not forthwith redelivered to him, he may have his action for damages, and in this action recover its value at the time of the demand, and perhaps (for this is not quite settled) any higher value it may have reached at any time while in the pawnee's hands. (Wilson vs. Little, 1 Sandford 351, and 2 Comstock 443; Allen vs. Dykers, 3 Hill 593, and 7 Hill 498.) This severe and somewhat technical rule is recent, and may need general confirmation before it can be regarded as established law. But there is for it this substantial reason. If a pawnee may use in this way stock pledged to him, he forces upon the pawnor the risk of his insolvency at the time when the stock should be redelivered. For if the pawnee be then insolvent, without the stock in his hands, the pawnor has only a claim against him for its value, and must take his dividend with other creditors. But if the pawnee retains in his hands the stock as the pawnor's stock, the pawnor then retakes it as his property.—A pledger may always transfer the pawn, but subject to the pawnee's claim; and if the transferee pay the debt, the pawnee must deliver the pawn to the transferee. The pawnee holds the pawn only as security, nor does it become absolutely his own if the debt be not paid at maturity. There is no forfeiture of the pawnor's right to redeem, until something has been done which is the same thing in its effect that foreclosure is in a case of mortgage. What this thing is may not be, in all cases and in all respects, quite certain. There is no doubt that the pawnee may apply to a court of equity and have a decree of sale, and may thereupon sell the pawn in compliance with the terms of the decree. Some authorities hold, or rather intimate that this, which was the ancient and regular way, if not the only one, remains at this day the best and safest. But we are satisfied that it is not necessary, and certainly it is not usual. We consider it as now established law, that a pawnee, after the maturity of the debt, and after unsatisfied demand, may sell the pawn, provided he do so in good faith and with all reasonable precautions in favor of the pawnor's interest. There is perhaps no other way of doing this, which satisfies the law, than a sale by public auction; and at all events this is the surest and most proper way. Nor will a sale by auction be conclusive against the pawnor, unless it is conducted, as to time, place, advertisement, notice to the pawnor, and in all other respects and circumstances, in such wise as to indicate perfect good faith, and to secure a due regard to the rights of the pawnor. The proceeds must be applied to the payment of the debt. If any balance remains over, that must be given forthwith to the pawnor. If any portion of the debt remains unpaid, the pawnee has an equally valid claim to that amount as he had originally for the whole. It is not unfrequent for the parties to agree, when the pledge is made, as to what shall be done with it; as, for example, that the pawnee may, if the debt be unpaid at a certain time, sell the pawn, if it consist of stocks, at the brokers' board. But any such agreement must be complied with literally and accurately. Thus, it would give no right to make any use of the stocks before maturity of the debt; nor to sell them without previous demand, nor in any other way than at the brokers' board. (See cases cited before.) It should be remarked, however, that negotiable bills and notes come under an exceptional rule. When they are pledged, it is said that the pledgee has much more power as to the use and disposition of them than of stocks; but this exception is not very accurately defined. So it should be said, that although delivery of possession is absolutely essential to the contract of pledge, and if the pledgee voluntarily parts with his possession he loses all lien or right to hold the pawn, this does not apply where the pawnee, in good faith, for a special reason, and for a limited time, returns the pawn to the pawnor, reserving all his rights over it. The pawnor may in that case be regarded as the agent of the pawnee, and as holding it for him. A pawnee, who takes a pawn as security for a specific debt or debts, cannot hold it as security for other debts from the pawnor, unless by a bargain between them.—It may be added that until a comparatively recent date, nothing seems to have been given in pawn, at least within the recognition of the common law, but personal chattels. But now personal property of all descriptions, all choses in action, and even patent rights or copyrights, may be given either in pawn or in mortgage.

PAWNEES, a tribe of Indians (4,500 in 1858) inhabiting the country on the river Platte and its northern tributaries. They were visited by Bourgmont in 1724, at which time they occupied their present position; but until after the acquisition of Louisiana their existence was scarcely known to the people of the United States. They raise corn and vegetables, and their hunting ground once extended as far south as the Arkansas river, and as far west as the sources of the Platte. Their language is different from that of the neighboring tribes. They are remarkable for endurance, daring, craft, and skill in horse stealing.

PAWTUCKET, a town of Providence co., R. I., on both sides of Pawtucket river, 4 m. N. from Providence; pop. in 1860, 8,880. Until 1861 this town was partly in Massachusetts; but by an agreement recently completed, the eastern boundary has been entirely changed and the whole of Pawtucket annexed to Rhode Island. The river has here a fall of 50 feet, supplying extensive water power. The first cotton manufactory in the country was established here by Samuel Slater in 1790, and for 40 years the place held the first rank among the manufacturing towns of the country. It now contains 18 cotton mills, 9 machine shops, 3 furnaces, 4 brass and copper founderies, 2 nut, bolt, and tool establishments, and 3 of jewelry, beside other manufactories of belting, leather, cabinet ware, hair cloth, tin, carriages, &c. There are also an extensive calico printing establishment and a manufactory of fire engines famous throughout the country. It contains 11 churches, 1 public library, 2 printing offices, 4 banks, 3 institutions for savings, and 2 public halls. During 1860, 200 vessels, chiefly laden with lumber, coal, and cotton, arrived. The town is beautifully situated, and has a most picturesque appearance, its stone bridge and waterfall adding to the effect of the scene. It has direct communication with Boston by the Boston and Providence railroad, and with Worcester by the Providence and Worcester railroad.

PAX (Lat., peace), an instrument anciently used in the Roman Catholic church, and retained for some time in the church of England. In the early ages of Christianity it was customary for the faithful at certain parts of the divine service to practise literally St. Paul's recommendation: "Greet ye one another with an holy kiss," as appears from the "Apostolical Constitutions" (viii. 11): "Let the bishop salute the church and say, 'The peace of God be with you all;' and let the people answer, 'And with thy spirit.' Then let the deacon say to all, 'Salute one another with a holy kiss;' and let the clergy kiss the bishop, and the laymen the laymen, and the women the women." But in course of time, when the separation of the sexes in the church ceased to be observed, a small tablet called the *pax*, the *tabula pacis* (tablet of peace), or the *osculatorium*, was kissed first by the bishop, then by the inferior clergy, and finally by the people. The ceremony called giving the pax, as performed in Roman Catholic churches at the present day, is merely a relic of the old custom. Just before the communion at solemn high masses the officiating clergyman turns to the deacon, and extending his hands and touching him on the arms, inclines his head toward the deacon's left shoulder, saying: *Pax tecum* ("Peace be with thee"); to which the deacon answers: *Et cum spiritu tuo* ("And with thy spirit"). The deacon gives the pax in the same manner to the sub-deacon, and each of the inferior ministers to the one next below him in dignity. The people have no part in it.

PAXTON, Sir Joseph, an English horticulturist and architect, born at Milton-Bryant, near Woburn, Bedfordshire, in 1803. His education was obtained at the Woburn free school; but his parents being in humble circumstances, he was early obliged to rely upon himself for support. Obtaining a situation at Chiswick, the suburban villa of the duke of Devonshire, he gained the confidence of that nobleman, who transferred him to Chatsworth, and subsequently made him the manager of his Derbyshire estates, and superintendent of the works which rendered Chatsworth the most celebrated country seat in England. In 1851 he laid before the building committee of the great industrial exhibition his plan of the crystal palace, and the design proposed by him was adopted and the work carried on under his superintendence. For this service Paxton was knighted. Since the completion of this edifice he has pursued the profession of an architect to some extent, and has been engaged in a variety of commercial enterprises. He constructed the greatly enlarged and remodelled crystal palace at Sydenham, and had the entire charge of laying out the pleasure grounds, fountains, &c., of that unique enterprise. In 1854 he was elected a member of parliament from Coventry, and in 1857 was reëlected. He was elected fellow of the horticultural society in 1826, and fellow of the Linnæan society in 1833; and in 1844 the emperor of Russia created him a knight of the order of St. Vladimir. He has written a "Practical Treatise on the Culture of the Dahlia" (1838), and a "Cottage Calendar," beside editing or assisting in editing "Paxton's Flower Garden," "Pocket Botanical Dictionary," "Horticultural Register," and the "Botanical Magazine."

PAYMENT, in law, is the discharge of a debt by a delivery of the amount due; and it is, of course, the most direct and most proper discharge of it, and the most complete defence against any claim founded upon it. The party entitled to receive the money may give notice to him who should pay it, that he requires the payment to be made directly to himself, and then no other payment discharges the debt; but without such notice, payment may be effectually made in the ordinary course of business to the creditor's general agent, or to his attorney. But the agent or attorney must be agent for that purpose. Hence payment to a man's wife, child, servant, clerk, or even attorney or auctioneer, has not the effect of a payment to the party himself, unless this authority to receive the money be shown; but it may be shown indirectly, by usage or other circumstances. Here, however, another general principle of agency comes in; and if the party receiving the money bears to the party paying it all the appearance of agency and authority, and this by the act or consent of the creditor, it is the same thing as if he were actually the agent. So an actual agent can receive payment only according to his authority; thus, if he is authorized to receive payment of a debt in money and receives it in goods or by note, and gives a receipt therefor, the principal is not bound by the receipt.—If there be joint creditors, as if two or more persons deposit money in a bank to their joint credit, a payment to either of them without the consent of the other does not discharge the debt. It is said, however, that payment to either of two or more joint executors discharges the debt; but payment to one of two or more joint assignees in insolvency, without the consent of the others, does not discharge the debt. In general, payment to a trustee is valid as against any claim of the party having the beneficial interest in the trust, even if he be defrauded by the trustee, unless the person paying be a party to the fraud or consent to it.—Formerly, a payment of a part of a debt was no satisfaction of the whole, even if that were agreed upon; the reason being that the creditor who promised to give up a large debt, all of which was due to him, on the payment of a part only, made the promise without legal consideration. Now, however, it seems to be established, that a fair and well understood compromise of a debt, honestly carried into effect, is a complete payment or discharge of the debt. Still, if a creditor compel payment of a part of his debt by process of law, when he might as well have sued for all, as if, when the several instalments are all due, he sues for one or two only, this will bar his claim for the remainder, because he has no right to put his debtor to the cost and trouble of repeated and unnecessary litigation.—Payment of money is often made by letter; and some difficult questions have arisen under this mode of payment. The law may, however, be stated thus. If the money reaches the creditor, the debtor is of course discharged. If it does not, he is still discharged if he was directed by the creditor to make the payment in this way, or if he can derive such authority from the certain and unquestionable course or usage of business; but not otherwise. The same rule or principle would apply, if the creditor sent the money, not by mail, but by an expressman, or by a private carrier.—As paper money or bank notes are in universal use in this country, and payment is generally made by them, the law on this subject is of much importance. The questions are: If the notes are forged, where is the loss? If the notes are genuine but the bank is insolvent, where is the loss? In the first place, it will be seen in the article TENDER, that any one to whom bank notes are offered in payment may refuse them and demand specie. If he accepts them, and they are forgeries, they do not discharge the debt, being considered in law mere nullities. If they are genuine, but not good by reason of the insolvency of the bank, the rules of law are more uncertain. It may be said, however, that generally, and where there is no fraud or negligence on either side, the loss in such cases falls on the party paying, and he must make up the difference between the actual and the nominal value of the notes. If the debtor knew of the insolvency and did not disclose it, here of course is fraud, and the debtor is at once liable. And if the debtor did not actually know the insolvency, but had sufficient means of knowing it, and must be considered as ignorant of it either through design or by negligence, such ignorance would affect him as knowledge would do. Still, however, the general rule, which casts the loss upon the debtor where there is no fraud or fault attending the payment, must be so far qualified, as that if the creditor receiving the money, by his subsequent negligence, as by receiving and retaining the notes without any inquiry or notice, prevents the debtor from profiting by any remedy or indemnity he might have had if due notice had been given him, the loss to this extent must fall on the creditor.—Payment is also often made by the debtor drawing his check upon a bank for the amount due, or by his presenting to the creditor some other man's check which he holds. Now a check is a draft, and, being payable to order or to bearer, is negotiable either by indorsement or by delivery; and it is in most respects embraced within the law of promissory notes and bills of exchange. (See NEGOTIABLE PAPER.) If the creditor draws the money, then of course payment is made. But if he fails to receive the money, it is no payment, unless this failure be his own fault; for he must not be negligent with it. It need not be presented on the day on which it was received, but it must be presented within a reasonable time thereafter; for if the bank would have paid it when it was drawn, but the check was kept a week, and then the bank failed, the creditor loses the money by this unreasonable delay. What delay is excusable, and what is not, is not settled by any positive rule, but is determined in each case by its own circumstances. If the drawer had no funds in the bank, and no adequate arrangement for funds, when he drew the check, it need not be presented at all in order to bind him, because the drawing of such a check, and using it as payment, was itself a fraud upon the creditor.—Payment is sometimes made by note; and if this be a negotiable note, it may be an absolute payment, discharging the original debt, and leaving the creditor no claim excepting on the note itself. The law of Massachusetts was quite peculiar in this respect; and as this was the law of Maine when they formed but one state, it continued to be the law of Maine after their separation. At present some part of this peculiarity remains. It may be said, however, to be the law of those two states, that if negotiable paper is given for the amount of a debt, the presumption of law is that it was given and received as payment thereof; but this presumption may be rebutted by proof that the parties did not so understand it. But in England and in all the other states, and in the courts of the United States, the presumption of law is against the note being a payment of the debt, without affirmative proof that it was so understood and intended.—Payment is sometimes made to a third party, to be held by him until some question is determined or some right ascertained. Such a third party becomes a stakeholder. For the rights and duties of a stakeholder in a case of wager, see WAGER. But one may be a stakeholder in other ways. Thus an auctioneer may receive from a purchaser a sum of money by way of deposit or security, to be kept by him until the title to the property bought can be investigated; and to pay it over to the seller if that be good, or to the purchaser if it be bad. If such a stakeholder pays the money over before the question is determined, he pays it in his own wrong, and at his own peril; for it is his duty simply to hold the money. And it is said that if such stakeholder pays the money to a creditor before his right is determined, the depositor may at once sue him and recover the money without any reference to the state of the question between the creditor and himself. But if the deposit be made by check, the stakeholder may draw the money, and hold it or even use it, without making himself liable for the amount.—The law of appropriation of payments is of much importance. It determines the right of applying a payment in one way or in another, or to one debt or to another. The general rule, upon which all others are founded, is, that whoever pays money may direct the appropriation as he pleases; or, in other words, pay it on such account as he chooses. But if the party paying the money makes no such appropriation, the party receiving it may make such application of it as he pleases. And if neither party make any specific appropriation (and an appropriation may be made in various ways), it rests with the law to make it according as the justice and equity of the whole case may require. These rules are held to apply even where the debts are of very different descriptions. Thus, if A owes B $100 on a bond, and as much more on a note, and as much more on simple book account, and pays $100, the appropriation of this payment shall be determined to one or other of these debts, in accordance with the above rules. As the payer may certainly appropriate the money as he will, if he declines doing so, this gives the payee the power of appropriating it at his pleasure, although in a way adverse to the payer. Thus, if A's wife owed money to B before marriage, and A also owes B, and A pays B a sum of money without specific appropriation, B may apply the money to the debt of A's wife. So, if A owes B two debts, one of which is more than 6 years old and so is barred, and the other is not, and pays money without appropriation, B may apply it to the debt which A was not legally compellable to pay; but he cannot by such appropriation revive the remainder of the barred debt, and then make B pay the balance. The appropriation, to have full force, must be made at or very near the time when the money is paid. For if either party, at some subsequent period, finds out what will be to his advantage, and then undertakes to make such a disposition of it, this will not avail him to the disadvantage of the other; but the law will consider this as a case in which it must make an appropriation because the parties did not. So also an appropriation by either party will not affect the other party unless it be communicated to him. Thus, mere entries in the books of either party do not affect the other party; but if these entries were shown to the other party, then they bind him. And although the payment be general, the creditor cannot make the appropriation, provided the debts due to him are due in different rights. Thus if A, as executor of C, owes B a debt, and also owes him a private and personal debt, and pays money generally, B must appropriate it first to the payment of the private and personal debt. Nor has the creditor the right of appropriation merely because the debtor did not make an appropriation, if the payment were made in such a way as to prevent the debtor from appropriating it; as on his account by some other person, or in any way which impaired his power of exercising his right.—Where the court makes the appropriation because the parties do not, it will generally favor the creditor so far as to apply it to the most precarious and least secured debt. But if there be two or more debts, and the sum paid will exactly discharge one of them, the court will consider that it was intended to pay that debt. If one of the debts be contingent or uncertain, as if B were the surety of A and might be bound to pay a certain sum if A did not, and A also owed B a certain and specific sum, and A pays a sum generally, B will not be permitted to hold it against his own suretyship, but must apply it to the specific debt. On the other hand, a court sometimes protects a surety, and, in his favor, will direct an appropriation of money paid generally; as if A buys goods of B, and C is the surety of A, and A pays to B money generally, B will be obliged, in justice to C, to apply the money to payment for the goods.—Payments are sometimes made by a debtor, not voluntarily, but by compulsion of law, or by his assignees. In such case there is no appropriation by either party, but the payment is applied to all the debts in proportion to their amount.

PAYNE, John Howard, an American actor and dramatist, born in New York, June 9, 1792, died in Tunis, June 5, 1852. He evinced in early youth a remarkable predilection for the stage, together with considerable literary precocity. At 13 years of age, while a clerk in a mercantile house in New York, he secretly edited a little periodical called the "Thespian Mirror," and showed so much ability in this capacity that a benevolent gentleman named Seaman offered to defray the expenses of his education at Union college. The bankruptcy of his father led to his departure from this institution before completing the collegiate course, and as a means of supporting the family he went upon the stage, making his debut at the Park theatre, New York, Feb. 24, 1809, as "Young Norval." The performance was entirely successful, and he subsequently appeared before large and enthusiastic audiences in Boston, Philadelphia, Baltimore, and elsewhere. In 1813 he visited England, and made his first appearance at Drury Lane theatre in the same year as Master Payne, the "American Roscius," in his original part of Young Norval. Both here and in the provinces his performances called forth much applause, and he was generally admitted to be superior to Master Betty and other youthful actors in similar parts. For nearly 20 years after this he pursued a career of varied success in England, as actor, manager, and playwright. He made translations of French dramas, and produced a number of original plays and adaptations, including "Brutus," "Thérèse, or the Orphan of Geneva," and "Clari," all of which proved highly successful, although but a small share of the profits came to the author. The first, produced in 1818, with Edmund Kean in the principal part, was made up in a great measure from 7 different plays on the subject, and still holds possession of the stage. "Clari," which was produced as an opera, contains the celebrated song "Home, Sweet Home" (written when he was near starving in an attic in the Palais Royal in Paris), which alone will preserve Payne's name from oblivion, and of which 100,000 copies were sold in a single year. Another successful play by him was "Charles the Second," the principal part in which was a favorite with Charles Kemble. In 1832 he returned to the United States; and after employing himself several years in literary pursuits, he received the appointment of American consul at Tunis, which office he held at the time of his death.

PAYSON, Edward, an American clergyman, born in Rindge, N. H., July 25, 1783, died in Portland, Me., Oct. 22, 1827. He was the son of a clergyman in his native town, was graduated at Harvard college in 1803, and then for 3 years took charge of an academy in Portland. In Sept. 1806, he became a member of the Congregational church in Rindge. While in Portland he had given much attention to theological studies, and, upon quitting his situation as teacher, pursued them under the direction of his father, paying especial attention to the critical study of the Bible. On May 20, 1807, he was licensed to preach, and on Dec. 16 was ordained colleague of the Rev. Mr. Kellogg, pastor of the Congregational church in Portland. There he remained till his death, although his health failed shortly after his acceptance of the post, and was never completely reëstablished. He declined in 1825 a call to Boston, and also in Jan. 1826 one to New York. He published "A Discourse before the Bible Society of Maine" (1814); "A Thanksgiving Sermon" (1820); "An Address to Seamen" (1821); and "A Sermon before the Marine Bible Society of Boston and its Vicinity" (1824). His works have been collected in

3 vols. 8vo., with a memoir of his life by the Rev. Asa Cummings, D.D.

PEA (Celtic, *pis*; Lat. *pisum*), a well known exogenous plant with diadelphous blossoms, whose seeds are employed for food. The several species of the pea are annual herbs with abruptly pinnate, tendril-bearing leaves, each having 3 pairs of leaflets and large foliaceous stipules; papilionaceous flowers, the calyx with 5 foliaceous segments, the 2 superior of which are the shortest; the corolla of 5 irregular petals, the upper or odd one (*vexillum*) ample and reflexed; the style carinated, villose above; the fruit a pod (legume), oblong, rather compressed, but not winged; seeds globose, numerous, with a roundish eye (*hilum*); cotyledons large and thick. The common pea (*pisum sativum*, Linn.) is a hardy annual, native of the south of Europe, and has been for a long time under cultivation. It has a weak stem, which supports itself by tendrils; terete petioles bearing 3 pairs of ovate, entire, glaucous leaflets with undulated margins, usually opposite and mucronulate, ovate, somewhat cordate, stipules crenated at their base; 2- or many-flowered peduncles, and rather fleshy legumes. The usual color of the flowers is white, but sometimes red. There are 5 principal and quite distinct forms of the common pea, and from these have originated many varieties; they are *saccharatum* (Seringe) or sugar pea, with a tall stem, legumes rather coriaceous, between terete and compressed, and seeds globose and distant; *macrocarpum*, with a large stem, large falcate legume, very much compressed, and not coriaceous, every part being edible, and large distant seeds; *umbellatum*, with quadrifid, acute stipule, many-flowered peduncles, terminal, and somewhat umbellate (the English crown pea); *quadratum* (Linn.), with very dense and square seeds (the *pois carré* of the French); and *humile*, with a weak and dwarf stem, legumes smaller and rather coriaceous, seeds approximate and roundish (usually known as the dwarf pea). Don gives the names of 24 varieties of the common pea used for sowing in European gardens; but 5 especially are highly recommended by the best horticulturists, viz.: the early frame, early Charlton, blue Prussian (prolific and superior, and suited for middle crops), blue imperial (a dwarf, fine, rich pea), and Knight's marrowfat (a tall and luxuriant grower, rich-flavored, and of the latest crop). The following named varieties are preferred in the United States, and come into bearing in the order in which they are here designated, viz.: Dan O'Rourke, blue imperial, champion of England, and marrowfat.—Peas seem to prefer a moderately rich, warm soil, and one not recently manured. When needed for early use, they are sometimes sown on a sunny border, sheltered by a high wall. Sometimes likewise they are forced by beginning at the time of sowing with a temperature of 40° to 50° F., and gradually rising to 60°, and after the flowering increasing the heat to 70°. In the spring, in order to forward the crop, the earliest sorts may be sown in pots and transplanted into rows, after they have grown an inch or more high. The sorts known to agriculturists as field peas are also numerous, but the principal are the gray and the white; and the best kinds of splitting peas are considered to be the "pearl" and the "Suffolk."—The pea, like the other members of the natural order of *leguminosæ*, is rich in nutriment, and is nitrogenous in its elements. Sir Humphry Davy found in 1,000 parts of pea flour 574 parts of nutritive matter, consisting of 501 parts of mucilage, 22 sugar, 35 gluten, and 16 insoluble extract. The pea is subject to the attack of a coleopterous insect known as the *bruchus pisi*, or pea weevil; the parent insect, visiting the young pods when the enclosed seeds are beginning to swell, deposits a tiny egg in the punctures it effects opposite to the pea; this is hatched into a grub, and this in turn is changed into the mature weevil toward the end of the year. Such seed peas are called buggy, and previous to sowing should be scalded. The stems and leaves are also attacked by a species of mildew which covers them with a filamentous and grayish web, impeding further growth of the plants. Deep and thorough watering at the roots will if applied in season remedy this evil, but usually the injury is too extensive before being discovered.—The sea pea (*P. maritimum*, Linn.) occurs on the sea beaches of England; its seeds, though bitter and disagreeable, have been eaten in times of scarcity and afforded relief. Several beautiful blossoming garden plants, known as everlasting pea, Tangier pea, and sweet pea, are species of *lathyrus*, a closely allied genus, but not employed for culture as table esculents.

PEABODY, Andrew Preston, D.D., an American clergyman and scholar, born in Beverly, Mass., March 19, 1811. He was graduated at Harvard college in 1826, at the age of 15. The 3 years subsequent to graduation were spent by him in teaching, and the 3 following years as a student in the Cambridge divinity school; and in 1832-'3 he was a tutor in mathematics in the college. On Oct. 23, 1833, he was ordained in the south parish church in Portsmouth, N. H., as colleague pastor with the Rev. Nathan Parker, D.D., whose death a fortnight later left him in sole charge of the parish, which he retained until Sept. 1, 1860. He then became preacher and Plummer professor of Christian morals in Harvard university, from which in 1852 he had received the degree of D.D. Dr. Peabody has been an industrious literary worker, as a contributor to periodical literature, and a lecturer for lyceums. He was for several years a leading writer in the "American Monthly" and the "New England Magazine," and for a long period one of the principal contributors to the "Christian Examiner." His connection with the "North American Review" in one or another capacity has been uninterrupted for nearly a quarter of a century, and since 1852 he has been its editor. He has also published more than 100 sermons, orations, tracts, and pamphlets of various kinds, a volume of "Lectures on Christian Doctrine," which has passed through 6 editions, and "Sermons of Consolation," which has passed through 3 editions.

PEABODY, GEORGE, an American merchant, born in Danvers, Mass., Feb. 18, 1795. His parents were poor, and his early education was acquired in the district schools. At the age of 11 he was placed as clerk with a grocer in his native town, but left him when he had attained his 15th year, and, after spending a year with his grandfather in Thetford, Vt., went to Newburyport as clerk for his elder brother, who had opened a dry goods shop there. The shop being consumed by fire, he next went with an uncle to Georgetown, D. C., where for the following two years the business was conducted in his name, though a minor. Finding himself in danger, if he continued in this relation, of being held responsible for debts he had not contracted, he withdrew from the business in 1814, and became a partner of Mr. Elisha Riggs in the wholesale dry goods trade, Mr. Riggs furnishing the necessary capital, and intrusting the management to Mr. Peabody. The next year the house was removed to Baltimore, where it soon attracted a large business, and in 1822 branch houses were established in New York and Philadelphia. In 1827 Mr. Peabody crossed the Atlantic for the first time to buy goods. In 1829, by the retirement of Mr. Riggs, he became senior partner in the house. More than once, on his visits to Europe, he was intrusted with important negotiations by the state of Maryland, which were invariably conducted with success. Early in 1837 he took up his residence permanently in England. In 1843 he withdrew from the firm of Peabody, Riggs, and co., and established himself in London as a merchant and banker. Through his exertions, the confidence in American responsibility, which had well nigh failed in the disastrous period of 1837, was maintained. He rendered repeated and important favors in this respect to the state of Maryland, which were gratefully acknowledged, but for which he refused all compensation. The house he established in London has been ever since its foundation the head-quarters of his countrymen in that city, and the centre of American news and intelligence. In 1852, at the bi-centennial anniversary of his native town of Danvers, he sent a toast in a sealed envelope, not to be opened till the day of the anniversary. That toast was: "Education a debt from the present to future generations;" and in order to pay his share of that debt, a check for $20,000 was enclosed, to be expended in the founding of an institute, lyceum, and library for the town. By subsequent gifts that amount has been increased to $60,000, and an additional $10,000 has been bestowed upon North Danvers, for a branch library. To the first Grinnell expedition to the Arctic ocean, he contributed $10,000. In 1856–'7 he gave the sum of $300,000, with a pledge to increase it to $500,000, to found an institute in Baltimore for the promotion of science, literature, and the fine arts.

PEABODY, WILLIAM BOURN OLIVER, an American clergyman, born in Exeter, N. H., July 9, 1799, died in Springfield, Mass., May 28, 1847. He received his education at Exeter academy and at Harvard college, where he was graduated in 1817. Subsequently he studied for the ministry under the elder Dr. Henry Ware in the theological school attached to the same institution, commenced preaching in 1819, and in Oct. 1820 was ordained pastor of a Unitarian society in Springfield, Mass., with which he remained connected until his death. A man of fine tastes and extensive knowledge, he was particularly well versed in the principles of landscape gardening, and in several departments of natural history; and to his exertions Springfield is mainly indebted for a cemetery ranking among the most beautiful in the country. He also did much to awaken a taste for natural history, through lectures at home and contributions to the "North American Review" on forest trees, insects, and birds. In connection with this subject he prepared at the request of the Massachusetts legislature a "Report on the Birds of the Commonwealth," which did much to arrest the wanton destruction of birds, and to convince the public of the important part they play in the economy of nature; and he also contributed a memoir of Alexander Wilson, the ornithologist, to Sparks's "American Biography." He was a frequent contributor to the religious and secular press, and wrote a few hymns and sacred poems of merit. A memoir of him by his brother, the Rev. O. W. B. Peabody, with selections from his sermons, and a volume of his essays and reviews, have appeared since his death.—OLIVER WILLIAM BOURN, twin brother of the preceding, died in Burlington, Vt., July 5, 1847. He was graduated at Harvard college in 1817, subsequently practised law for a number of years in Exeter, N. H., during which time he edited the "Rockingham Gazette and Exeter News Letter," and in 1822 removed to Boston, where he coöperated with his brother-in-law, Mr. A. H. Everett, in the editorship of the "North American Review." At the same time he was for several years assistant editor of the "Boston Daily Advertiser." In 1842 he accepted the professorship of English literature in Jefferson college, La., hoping to repair his shattered health by a residence in a milder climate. Failing in this, he returned to Boston; and in 1845, in compliance with a desire long entertained, he was licensed to preach by the Unitarian association of Boston. He soon after became the minister of a congregation in Burlington, Vt., in which office he continued during the remainder of his life.

PEACE RIVER. See HUDSON'S BAY TERRITORY, vol. ix. p. 324.

PEACH, a delicious and well known fruit originating in Persia, and for a long period familiar to horticulturists. The peach tree (*amygdalus Persica*, Linn.) has been found growing wild in various parts of Turkey in Asia, and seems to flourish best under cultivation between lat. 30° and 40° N., extending even further N. in the United States. The peach tree belongs to the natural order *drupaceæ* or almondworts, according to Lindley, which are trees or shrubs with simple, alternate leaves, usually bearing glands toward their base; simple and mostly glandular stipules; white or rose-colored flowers, either produced singly or in umbels, the calyx 5-toothed, deciduous, lined with a disk; the petals 5, perigynous; the stamens about 20, arising from the throat of the calyx; the anthers innate, 2-celled, bursting longitudinally; styles terminal with a furrow on one side, ending in a uniform stigma; the fruit a drupe with the nut (putamen) sometimes separating spontaneously from the flesh (sarcocarp), seeds mostly solitary; cotyledons thick, plano-convex; albumen none. To this order belong many valuable trees, such as the almond, the plum, the apricot, cherry, &c. The peach tree has a low and branching trunk, an irregular head of numerous brittle branches and twigs, oblong-lanceolate, serrulate leaves, solitary flowers, and a downy or smooth drupe, with tender, succulent, and highly flavored flesh. There seem to be no positive distinctions between the peach and nectarine, the presence or absence of down upon the fruit being apparently accidental. Numerous instances are known where the same tree has produced both fruits, and sometimes upon the same branch, and where likewise a fruit has been partly nectarine and the rest peach. There are two prominent characters distinguishing the sorts, which are however found equally in the nectarine, where the fruits are known as freestones and clingstones, the flesh parting readily from the stone or nut, or else adhering closely to it.—The peach tree considered as an ornamental shrub has several beautiful forms or varieties, viz.: the double-flowering, with large showy blossoms like small roses; the white-blossomed, very ornamental, with fruit of little value; the variegated-leaved; and the flat peach of China, with almost evergreen foliage and singularly shaped fruit, which can be treated as a pot plant with much facility. A curious variety with pendent branches and large white flowers, called the weeping peach, is of American origin.—The peach succeeds as a fruit tree wherever the winters are not severe enough to kill the young wood. In England it withstands the usual winter weather; it is a standard tree in Italy and the south of France. In the United States, where the winters are more severe, it still does well, owing to the higher temperature of the summers. Where the peach is not extensively grown in orchards, it is frequently planted between other fruit trees, and in apple orchards; peach trees thus planted thrive for a few years, gradually giving place to the growing and overshadowing apple trees by their natural decline. In gardens it is well to plant them on the borders or near the walls, and a sheltered situation near the dwelling house often proves advantageous. The peach is also raised in structures of glass, either heated artificially by flues or warmed by the sun. It forces well, the precaution being taken so to regulate the heat that a sufficient space of time shall be allowed for the perfect foliation, blossoming, and maturing of fruit. Sufficient moisture should be judiciously applied to the roots during the growth of the tree and previous to the ripening. Pruning is unnecessary in outdoor standard trees; but if practised, the new shoots should be shortened so as to allow 6 or 8 inches of strong wood. In artificial management the pruning should be carefully attended to. Frequently old trees of esteemed kinds become very irregular in their heads, by the tall and straggling branches; and it has been found to be a good plan to tie such branches loosely together by ropes to prevent the winds splitting them down when laden with fruit. The fruit buds are produced upon the young branches, and are round and plump; the leaf and shoot buds are oblong and pointed; therefore in pruning care must be taken to cut down to the pointed buds, rather than to the round and plump ones, so that a new leafy branch above the fruit can be secured. The finer varieties of the peach, and those thought to be tender, are sometimes trained against walls or on espaliers; but the great facility with which the peach ordinarily grows, and the abundant crops it produces almost without care, have made its cultivation a matter of little attention here, not even receiving so much as is bestowed upon other trees.—The fruit of the peach tree abounds in varieties, the London horticultural society's catalogue for 1842 giving a list of 28 distinct sorts, each of which has many synonymes. Downing reckons the number cultivated in Europe to be about 50, while in this country innumerable seedlings have been produced, and some of them of the highest excellence. The comparative want of sunshine and of heat in England causes the finest American sorts to fail there in point of flavor and worth. Among the best foreign sorts may be cited the Barrington, Bellegarde, chancellor, early Ann, George IV., Heath, Malta, noblesse, and royal George, which succeed under our cultivation; and the following superior sorts are of American origin: Crawford's early melacoton, Crawford's late melacoton, Cooledge's favorite, late red rareripe, lemon clingstone, Morris's red rareripe, Morris's white rareripe, Oldmixon freestone, president, and red rareripe (early). There are many others of perhaps equal worth, which are but little known beyond the localities where they originated.—The peach tree is very easily propagated. This may be done by the seeds of superior kinds, or from fruits which have been cross impregnated, and by budding the young seedlings of the first year's growth, toward the middle of September. This process is so successful that any other is seldom used. On planting out the peach tree, it is found advisable to severely head it down, as thereby the growth is made more vigorous and hardy. Close pruning is often found serviceable in the same way for established and standard trees. The plum tree is used for stocks with advantage, especially for trees intended for walls and espaliers, as thereby a dwarfer habit is obtained. The best soil for the peach is a rich sandy loam; next to this, a strong mellow loam; then a light, thin, sandy soil. The last has been considered the best, but it has been found that the tree does not last so long as in a richer soil.—The diseases incident to the peach tree are the yellows, the curl, and the gum. The origin of the first and most fatal disease is not clearly known, but it is supposed to indicate an original and organic taint, transmissible through the seed; such trees as possess it should be eradicated and their seeds not sown. The curl attacks the leaves, swelling and distorting them, and causing them to prematurely fall. This disease has been attributed to the cold of the spring, or to aphides, insects which nestle in the affected leaves; but as the same appears in conservatories and on trees grown in pots under glass, the first named conjecture cannot be true. It is more probably owing to the presence of myceloid threads of a minute fungus which, growing in the tissue of the leaf, produces a rapid and abnormal growth, and affords thereby a succulent pabulum to the aphides as well as a secure and warm retreat. The gum is owing to the depredation of the peach tree borer (*ageria exitiosa*, Say), a lepidopterous insect like a blue fly, which deposits its eggs under the bark; these, hatching into worms, devour the inner bark and cause the extravasation of the sap, which on exposure to the air is converted into gum. Destroying the insect is the only cure.—The value of the fruit of the peach tree in a commercial point of view in the United States is very great. Thousands of bushels of peaches are marketed from the peach orchards of the middle states yearly. In western New York and in other parts of the country, the fruit is dried by artificial heat, the stones being taken out previously, or even dried in the sun, and thus made a marketable article. A spirituous liquor called peach brandy is distilled from the ripe fruit, and hogs are fed from the refuse. The leaves of the peach tree, bruised in water and distilled, give peach water, much esteemed for flavoring articles in cookery; and when steeped in spirits they communicate to them the flavor of noyeau. The medicinal qualities of the peach tree may be considered as nutritious and refrigerant, the bark, blossoms, and skins of the seeds being poisonous. The almond (*A. communis*, Linn.) is considered by some botanists as only a species of the peach, the general appearance being very similar; but the sarcocarp is uneatable, being destitute of pulp, tough, and fibrous. The peculiar bitter principle resident in the seeds of the variety known as bitter almond and in the leaves of the peach is attributed to the presence of hydrocyanic acid.

PEACOCK, a gallinaceous bird of the pheasant family, and sub-family *pavoninæ*, which includes, according to Gray, the genera *pavo* (Linn.), *polyplectron* (Temm.), and *crossoptilon* (Hodgs.), all natives of India and its archipelago. In the genus *pavo* the bill is moderate, with the base of the culmen elevated, the apical half arched and vaulted, and the sides compressed; wings short and rounded, with 6th quill the longest; head plumed and crested, and orbital region naked; the tail composed of 18 feathers, long and rounded, but in the males concealed by the greatly lengthened coverts; tarsi long and strong, with large transverse scales in front, and armed with a conical spur; toes moderate, the anterior ones united at the base by a membrane. They are splendid birds, preferring in the wild state wooded districts and low jungles; they are sufficiently hardy to endure the severe cold of the mountains of northern India; they roost on high branches, and make the nest on the ground among thick shrubs; the male does not attain his perfect train until the 3d year. The wild birds are more brilliant than the domesticated; Griffith says of them: "We find in their incomparable robe all that glistens in the rainbow, and sparkles in the mine—the azure tints of heaven, and the emerald of the fields." They are about the size of a hen turkey; the flight is low and heavy; they are polygamous, and lay from 12 to 20 eggs, about the size of those of a goose, and raise only one brood in a year. Some are more or less variegated, and occasionally one is seen entirely white. The food consists of grain, seeds, fruits, and insects. The common peacock (*P. cristatus*, Linn.) is probably the most magnificent of birds; its form is elegant, its movements graceful, and its plumage resplendent with tints of green, golden, bronze, and blue; the long tail coverts, which the male can spread like a fan, are beautiful beyond description, with their metallic and iridescent hues, white shafts, velvet-black centre, and brilliant terminal eye spots; the head is surmounted with a very elegant tuft of feathers; every one must have seen its display in public or private parks. The female is brownish and sombre, and destitute of the train. The voice is harsh and disagreeable, resembling the syllables *paon*, which is the French name for the bird; it is very fond of being admired, and its vanity has been proverbial from early antiquity; it has been asserted that the principal use of its train is, by its sudden spreading, to bewilder and terrify its enemies; it has not this effect, however, upon the tiger, to which this bird falls a frequent victim. The peacock was brought to Palestine by the fleets of Solomon, and to Europe at a very early period; it is now dispersed in a domesticated state all over Europe and the United States. In ancient Rome their costliness made them favorite luxuries for the table, and a dish of peacocks' brains and tongues was regarded as a necessary part of an ostentatious feast; even in the middle ages they formed a standing dish in grand entertainments; the moderns think their flesh dry and tough, and keep them only as ornaments. In the domesticated state they agree well with turkeys, but not always with the other occupants of the poultry yard; it is necessary to protect them from the cold of our northern winters; in the wild state they have a propensity to roost on the branches of trees, and should therefore have an opportunity to perch, either on a tree, wall, or roof; barley is the most common food given to them, and to this may be added millet and other grains, and leguminous vegetables; the females are apt to neglect their eggs and young, hence the services of a hen turkey are generally required to raise the brood. The green peacock (*P. muticus*, Linn.), from Java, has the neck greenish and copper-colored, and a tuft of long thin feathers barbed from the base on the top of the head. Mr. Sclater ("Annals and Magazine of Natural History," Aug. 1860) makes a distinct species of the black-shouldered peacock of Latham, under the name of *P. nigripennis;* this bird has long been known in aviaries, but has been considered as a variety or hybrid of the other two; he regards it as intermediate in geographical position as well as in characters between the *P. cristatus* and *muticus.*—In the genus *polyplectron* the bill is slender, straight, half vaulted at the apex, and curved to the tip, with compressed sides, and covered with plumes at the base; the tail is lengthened, broad, and rounded, without the long coverts of the preceding genus; the tarsi armed in the males with 2 or 3 spurs, in the females tuberculate; toes long and slender, the anterior united at base, and the hind one elevated. There are about half a dozen species, all showy birds, found in mountainous districts of India. The iris peacock (*P. bicalcaratum*, Temm.) is about as large as a domestic fowl, mottled with ash-colored, white, and brown; wings and tail and their coverts with rows of gilded, bronzed, purple, and reddish spots, with bluish and green reflections. The Thibet peacock (*P. Tibetanum*, Temm.) is a rather larger bird, and differs principally from the last in the blackish lines of the plumage; the tail is reddish, each feather having a double ocellated green spot; it is a hardy bird, and a great favorite in the aviaries of the wealthy Chinese.—In the genus *crossoptilon* the bill is shorter than the head, broad at the base, with the lateral margins curved, the upper mandible spreading beyond the lower and overhanging it; tail lengthened and broad, rounded at the end, with the coverts slightly covering the base; tarsi strong, covered in front with divided scales, and armed with a spur; hind toe short and elevated; claws strong and curved; sides of the head covered with a papillose skin; the feathers loose and hair-like. The single species described (*C. auritum*, Hodgs.) is peculiar to the mountains of Thibet, and is very rare; the general color is white, with the primaries brown, the secondaries bluish cinereous, the feet and orbital region red, and the crown bluish black, of rigid feathers in vertical laminæ; an ear tuft of long, decomposed white plumes; the tail with bluish, green and purplish reflections, the lateral feathers with a subterminal oval white spot.

PEALE, Charles Wilson, an American painter, born in Chesterton, Md., April 16, 1741, died in Philadelphia in 1827. He was originally by trade a saddler, but at various times of his life followed the occupations of harness maker, watch and clock maker, silversmith, painter in oils, crayon, and miniature, modeller, preserver of animals, dentist, public lecturer, &c. Painting however was his chief employment, the others being incidental to it, or assumed for temporary purposes. He received instructions in art from a German painter named Hesselius, who had been a pupil of Sir Godfrey Kneller, and subsequently from Copley, then living in Boston. In 1770 he visited England, and for several years was a pupil of West. Returning to America, he established himself first in Annapolis and afterward in Philadelphia, and for many years was almost the only portrait painter deserving the name in North America, his reputation being such that people came to him from Canada and the West Indies to be painted. During the revolutionary war he commanded a company of volunteers, with whom he participated in the battles of Trenton and Germantown; and he also painted the portraits of many officers and distinguished men, which formed the nucleus of a national portrait gallery subsequently collected by him. He also served in the Pennsylvania legislature. About 1785 he commenced the formation of a museum of natural curiosities, the idea of which had been suggested to him by the sight of some fossil bones, brought to him to be copied. In a few years his collection of pictures and other objects was removed to a large building specially prepared for their reception, which, under the name of Peale's museum, was long one of the principal attractions of Philadelphia. Subsequently the entire skeleton of a mammoth was added to the collection, and in connection with his museum Mr. Peale lectured on natural history. He aided in founding the Pennsylvania academy of fine arts, to 17 annual exhibitions of which he was a contributor.—Rembrandt, 2d son of the preceding, born in Bucks co., Penn., Feb. 22, 1778, died in Philadelphia, Oct. 3, 1860. At the age of 8 he was a tolerable draughtsman. In 1796 he established himself in Charleston S. C., as a portrait painter, and between 1801 and 1804 he studied in London under West. Subsequently he passed several years in Paris, and executed portraits of eminent men for his father's museum. In 1809 he returned to Philadelphia, where during the next few years he painted many portraits, and also two pictures celebrated in their time, the "Roman Daughter" and the "Court of Death," the latter founded on a passage in Bishop Porteus's poem on death. This work, which was 24 feet in length by 13 in breadth, and contained 23 figures, was exhibited in the chief cities of the United States, and brought the author a large sum of money. Thenceforth until near the close of his long life, he devoted himself chiefly to portrait painting, numbering some of the most eminent men in the country among his sitters. The work in this department by which he was chiefly known was his portrait of Washington made from life studies. He published a book of European travels, and a small treatise on elementary drawing entitled "Graphics."

PEANUT, the seed of the *arachis hypogæa* (Linn.), an herbaceous plant belonging to the pulse family of the natural order *leguminosæ*. This order comprises the leguminous plants, a vast group, which, though differing in the structure of the flowers, yet unite in the common form of the seed vessel, which is that of a pod. The peanut has an annual root; a procumbent stem from 9 to 18 inches long, branching and pilose; leaves borne on petioles and consisting of 4 broad, blunt leaflets in pairs, subsessile, minutely mucronate at the apex, entire and bordered by a pilose nerve, the stipules adnate to the petiole. The flowers are papilionaceous, the barren ones yellow and small, and the fertile destitute of calyx, corolla, and stamens; the ovary after impregnation gradually elongates, and curving downward buries itself in the earth, where it matures into an oblong, terete pod, with thickened and reticulately veined indehiscent valves; this when mature is of a pale yellow color, often contracted in the middle, and contains 1 to 3 seeds of an irregularly ovoid shape, with thick cotyledons and a straight radicle. The seeds are full of oil, which when expressed is said to be in no way inferior to that of olives. The plant is tropical, and is largely cultivated in hot countries for food, as in the southern United States, in South America, and in Africa. The seeds are eaten both raw and roasted.

PEAR, an edible fruit, the produce of the *pyrus communis* (Linn.). In its wild state the pear tree has a pyramidal-shaped head, with thorny branches, at first erect and afterward becoming pendulous and curving downward; the leaves varying greatly in form, and downy or glabrous, narrow or broad; the fruit small, austere, and unfit to eat. The wild pear tree is a native of Europe from Sweden to the Mediterranean, and of Asia as far east as China and Japan. From the variety of the common pear designated as the *sativa* by De Candolle all the fine garden sorts of pears have originated. The pear tree belongs to the natural order of *pomaceæ*, being exogens with rose-like, many-petalled, regular flowers, and carpels adhering to the calyx by their backs. The distinctive characters of the pear tree properly so called are: leaves simple, without glands; flowers with the calyx urceolate, the limb 5-lobed, the petals 5-spreading, flat, and white; stamens indefinite, inserted in the throat of the calyx; styles mostly 5; fruit a fleshy pome, containing about 5 cartilaginous carpels; seeds 2 in each carpel; embryo erect with flat cotyledons. The cultivated pear tree has been known from very remote times, being mentioned by the earliest writers and familiar to Theophrastus and Virgil. Pliny describes numerous varieties known to him, and from his remarks it would appear that the earlier ripening kinds and the winter pears were then in existence. It is conjectured that the pear was introduced into England by the Romans; and some of the older sorts still in existence are mentioned by name in the account books of the exchequer in the time of Henry VIII., and by Gerarde, a celebrated herbalist, who published a catalogue of trees, &c., as early as 1596; while, according to Miller, who wrote in 1795, the number of cultivated varieties known was 250, from which he selects 70 or 80 as the best. Since that time the number has been constantly increasing from the efforts of the French, and especially of Van Mons of Belgium, while in England and America very fine and luscious sorts are annually springing into existence through the sowing of seeds and by hybridization. Through the efforts of gentlemen connected with the London horticultural society's garden, all the varieties that could be obtained were collected and classified; and in its catalogue published in 1842 no fewer than 442 kinds are specified, with their accompanying synonymes. In the United States the readers of the various horticultural magazines are familiar with the hosts of improved and valuable varieties which have since originated or been introduced to notice.—The cultivated pear tree thrives in any rich loamy soil, and manure judiciously applied proves very beneficial. Old trees which have ceased to bear good fruit have been renovated by digging around their roots and applying a compost of well rotted manures mixed with vegetable matters, soap suds, ashes, &c. The perfection of the fruit and the flavor of particular kinds depend very much upon the nature and quality of the soil; and particular varieties have been found to do perfectly well in situations which vary in some essential particular from others in their vicinity. The pear is cultivated in a variety of modes, being set out as a standard tree, when it is grafted upon some seedling stock and suffered to grow to great size; or used as a dwarf tree, by being grafted upon the quince root; or planted near walls and grown upon espaliers, when its training and pruning are still more constrained and artificial. The modes of training dwarf and wall trees are various, but on walls the 3 principal methods are the fan-shape, the pendulous, and the horizontal. The main object being, however, to distribute equally the vigor of the tree, it has been found that the last named mode is the best. This is done by cutting back a central shoot and training branches horizontally to the right and left. For market gardening and for farmers the standard trees are the best, many bushels of fruit being raised on single trees. For small gardens the dwarf trees are preferable, enabling many choice varieties to be grown near together and on a small area. Sometimes such trees are trained into artistical forms by tying the young and growing branches to stakes, or by bending them down toward the earth, securing them in such position by strings and pegs. In making a selection, the peculiarities of the different varieties, in reference to their stocks, soil, and crops, should be studied. Some will not grow in the open country, and require the shelter of the garden; some do best grafted on the pear, and others on the quince; and others require more than ordinary management. The great variety of climate in the United States enables the fruit grower to find congenial situations for every foreign sort, and accordingly treatises on pear culture assign certain sorts to certain sections. For the farm, standard trees of the following autumn and winter fruits have been recommended, viz.: Catillac, Chelmsford, black pear of Worcester, Spanish bon Chrétien, Uvesdale's St. Germain, and vicar of Winkfield. For a succession of early, autumn, and winter fruits in small gardens, among others the following foreign kinds may be named: Madeline, Williams's bon Chrétien, summer franc réal, white doyenné, fondante d'automne, Marie Louise, Urbaniste, Van Mons' Léon le Clerc, beurré Bosc, winter Nelis, and beurré d'Aremberg; and of American seedlings, the Bloodgood, Dearborn's seedling, Andrews's, Seckel, Dix, Columbia, &c.—The value of the pear is twofold, viz.: for the dessert, and for baking, stewing, and preserving. Dried pears are as well known in France and Belgium as dried apples are with us. Dessert pears embrace not only the summer kinds which ripen on the trees, but some of the winter kinds which are not fit for eating until toward the following spring. To ripen these it has been found convenient to construct fruit rooms in which the pears are laid separately on shelves and kept as nearly as possible at a uniform temperature. Another use of the pear is for making from its juice a liquid called perry, which is richer and more esteemed than cider. In some parts of England, France, and Germany there are particular varieties called perry pears. Several trees of such are mentioned by M. Bosc as being about 400 years old; and according to Loudon a very extraordinary tree in the parish of Holm-Lacey, Herefordshire, England, has yielded from its fruit 15 hogsheads of perry in a year. The best English perry pears are the Barland, Longland, Oldfield, and Teinton squash. The great age to which the pear tree may attain indicates somewhat the value of its wood as timber. It is heavy, strong, and compact, and can be used in making joiners' tools and in cabinet work; it also furnishes a good fuel and excellent charcoal.—The pear tree is subject to two principal diseases, which are very injurious to the cultivator, known as blights, but originating from very distinct causes. The young branches are sometimes attacked by a mischievous coleopterous insect, first described by Prof. Peck in the "Massachusetts Agricultural Repository," vol. iv. No. 3, as the *scolytus pyri*, which bores into the bark and wood, and cuts off the passage of the ascending sap; when this supply fails the branches suddenly perish. The other disease is the effect of late growth during the previous autumn and of imperfect ripening of the wood, in consequence of which it becomes frozen and the tissues killed and disabled from carrying on the vital functions; this is termed the sap blight or frozen sap blight. Varieties of the pear tree which mature their wood early are rarely affected in this way.—The true pear tree is not represented in the American flora, and its nearest species in the natural order *pomaceæ* is the American crab apple (*pyrus coronaria*, Linn.) of western New York, and the western and southern states.

PEARCE, Zachary, an English prelate and scholar, born in 1690, died in Little Ealing, June 29, 1774. He was the son of a Holborn distiller, and was educated at Ealing, at Westminster under Dr. Busby, and at Trinity college, Cambridge. While in college he is said to have written two numbers of the "Spectator" (572 and 633), and Nos. 114 and 121 of the "Guardian." In 1716 he published an edition of Cicero *De Oratore*, with notes and emendations, and dedicated it to Lord Chief Justice Parker, who caused him to receive various preferments. In 1724 his edition of "Longinus on the Sublime," with a new Latin version and notes, appeared. In 1739 he was made dean of Winchester, in 1748 bishop of Bangor, and in 1756 bishop of Rochester with the deanery of Westminster added, and later was offered the bishopric of London, which he refused. When 73 years old he wished to resign his offices, and for that purpose had an interview with the king; but in consequence of the disapproval of the episcopal bench, George III. refused him permission. Beside the works already mentioned, he published a "Review of the Text of Paradise Lost," in opposition to the emendations of Bentley; "An Account of Trinity College, Cambridge;" "The Miracles of Jesus Vindicated," in 4 parts (8vo., 1727-'8); beside a number of sermons, treatises, and discourses on various subjects. His greatest work was published after his death, under the title of "A Commentary, with Notes, on the Four Evangelists and the Acts of the

Apostles, together with a new Translation of St. Paul's Epistle to the Corinthians" (2 vols. 4to., 1777). A collection of "Sermons on Various Subjects," from the manuscripts of Bishop Pearce, appeared in 1778 (4 vols. 8vo.), with a dedication to George III. by Dr. Johnson.

PEARL, a round, tubercular, or irregular concretion, consisting chiefly of carbonate of lime, found in many bivalve shells, especially in the *avicula margaritifera*, or *meleagrina margaritifera* of De Lamarck, or the true pearl oyster, and among fresh water bivalves in the *unio margaritiferus*. (See MUSSEL.) In form they are usually spherical, and their color is yellowish or bluish white. The purest white pearls are most esteemed in Europe and America, and those of yellowish tinge by the Hindoos and Arabs. Their hardness somewhat exceeds that of calcareous spar, though when treated with acid they are found to possess the same composition with this mineral, with the addition of fine films of membrane or albuminous matter, which remains behind, retaining the form and structure of the pearl, and in nacreous pearls the iridescence also. They differ in structure according to the portion of the animal in which they are found. Those developed in the inner layer of the mantle and in the gills are often of small size and numerous, and are known as seed pearls. Others are formed around particles of sand or other foreign bodies introduced into the pallial cavity. These consist of concentric layers of wavy calcified membrane, but the external pearls from the outer layer of the mantle and attached to the shell consist of a concentric layer of minute vertical prisms. The Chinese have long been in the habit of causing the formation of pearls by introducing into the shells small beads of mother-of-pearl or other substances, which soon collect an incrustation of calcareous matter. It is supposed that the natural secretion of the substance of pearls is always owing to some injury the animal has received. Linnæus first called attention to this phenomenon, and was knighted for demonstrating the fact.—From a very early period pearls have ranked among gems, and been highly esteemed as ornaments. In the time of Job they were accounted of great value, and frequent allusions are made to them in the Scriptures. The Greeks and Romans used them in profusion, and even decorated their feet with pearls. Pliny, after referring to the prodigal display of pearls in his time, adds: "Nay, even more than this, they put them on their feet, and that not merely on the laces of their sandals, but they must needs tread upon them and walk with them under foot as well." He also alludes to the breastplate which Cæsar brought home and dedicated to Venus Genetrix, stating that it was formed of British pearls; which confirms the statement of Suetonius, that pearls were Cæsar's chief inducement for his British expedition. The two famous pearls of Cleopatra, which she proposed to dissolve in vinegar in honor of Antony at her luxurious repast, must have been of extraordinary size, as they were valued at 10,000,000 sesterces, or about $400,000. At the Paris exhibition of 1855 Napoleon III. exhibited an enormous pear-shaped pearl. The largest known in modern times belongs to O. A. J. Hope, Esq., of England. It weighs 3 oz., and is 4½ inches in circumference and 2 inches in length, but irregular and imperfect. The art of piercing and drilling them is well understood and skilfully executed by the Hindoo artisans. They drill a number of holes of varying sizes over the surface of a soft board, into which they insert the pearls, which are secured by dampening the board and so causing the pores to expand and the wood to tighten round the pearls until drilled, when the board is allowed to dry. A slight tap disengages them.—The pearl oyster, from which almost all the pearls of commerce are obtained, is a bivalve of nearly circular form, slightly convex, and sometimes as large as 12 inches in diameter. It is met with in different parts of the world, especially in the Indian ocean and the northern Pacific. Like the common oyster, pearl oysters congregate in large numbers on banks, and are obtained year after year from the same localities. Where the water is shallow, they are sometimes dredged, but they are generally taken by divers. The most famous pearl fisheries are near the coasts of Ceylon, Japan, Java, and Sumatra, and in the Persian gulf. The coast of Colombia and the bay of Panama were long since famous for their product of pearls, and they have furnished large amounts of them, but generally of inferior value to the oriental pearls. Still, one possessed by Philip II. of Spain, obtained in 1574 from Margarita, weighed 250 carats, and was valued at $160,000. The Spaniards who first visited the American continent found the natives decked with necklaces and bracelets of pearls, and Montezuma is described in his first interview with Cortes as wearing garments adorned with this precious ornament. In the trade in pearls from the Spanish American coast which soon sprung up, the islet of Cubagua became famous for the abundant supplies it furnished. On the W. coast of Central America pearls are still procured. They are of fine lustre, but of irregular forms. Small vessels from Mazatlan and Acapulco are employed in this business. Beside the crew, they carry Indian divers, called *buzos*, who receive for their services ½ of the profits, the remainder being equally divided between the government and the owner of the vessel. Humboldt remarks with surprise that he had never heard of pearls found in the fresh water shells of South America, though several species of the *unio* genus abound in the rivers of Peru. The accidental discovery at Paterson, N. J., in 1858, of some of unusual size, occasioned the New Jersey pearl excitement of that time, which was no doubt heightened by the largest having been found at the commencement of the search; it was a pearl of more than an inch in diameter, perfectly spherical and with fine orient; it was purchased by Messrs. Tiffany of New York, and disposed of through their establishment in Paris, where it is said to have become the property of the empress at a price exceeding $2,000.—Among the most famous pearl fisheries are those of Ceylon and Coromandel, which are now controlled by the English government, as formerly by the East India company. From the time of Pliny, when the Romans obtained their pearls from the same region, Ceylon has always been celebrated for its pearls and its pearl divers. At present the fisheries are annually surveyed and farmed out to the highest bidders, each portion being fished only once in 4 years, that the young oysters may have time to grow. The divers are natives trained to this pursuit, and accustomed to descend to depths of 6 or 8 fathoms 40 or 50 times a day. They take down a large stone to hasten their descent, and a bag in which they place the oysters, as they tear them off from the rocks. They remain under water a minute to a minute and a half, and come up with about 100 oysters. The occupation is very laborious, and the divers are unhealthy and short-lived from diseases of the heart and lungs and congestion of the brain during immersion; they also run great risks from the attacks of sharks and the large hook squids. The fishing season commences in March or April, and continues about a month. For a few months the bay of Condatchy, on the W. coast of the island, which is the most attractive point in this fishery, presents a most lively scene, in striking contrast with its usually quiet aspect. A motley crowd of people of various nations, with their strange diversities of dress, language, religion, and manners, is collected from all directions—Brahmins and Roman Catholics, Mohammedans and Jews, merchants and divers—all eager and excited in speculation and trade. Sometimes not fewer than 150,000 persons are thus assembled, living under the temporary shelter of light bamboo huts. At daybreak the boats start off at the firing of a gun, and at noon their return is signalled in the same manner. On landing, the freight is delivered to the owners, and some of the shells are immediately opened and the pearls extracted; others are piled in large heaps and left in the sun till the bodies of the animals putrefy, when they open of themselves and the pearls are removed. These are passed through a succession of sieves, and thus those of corresponding sizes are brought together. A single shell often contains from 8 to 12, and in some instances it is said even 20 pearls. The usual dimensions of good oriental pearls are from the size of a pea to about 3 times that size. Those smaller are called ounce pearls from being sold by weight, and the smallest seed pearls. To the latter are attributed important medicinal virtues by the natives of Japan and India. The pearl fisheries of the Bahrein islands in the Persian gulf are said to yield annually from $1,000,000 to $1,200,000.—Pearls are valued as well for the purity of their lustre as for their size. The smaller ones are worth from 50 cents to $3 each; single fine pearls are worth $5 and upward; and a handsome necklace of pearls as large as peas is worth from $500 to $15,000. Pearls in commerce are classed as oriental and occidental, or Indian and Pacific, and divided into round, pear-shape, and baroque; when smaller than $\frac{1}{12}$ of an inch in diameter, they are termed seed pearls. The Saxon, Scotch, Welsh, and Irish are from the same source as our New Jersey pearl, the fresh water mussel (*unio*). The beautiful pink-colored West Indian conch pearl, and our clam pearl, are not strictly pearls, being mere calcareous aggregations, seldom nacreous, and never concentric as the true pearl is.—Nacre or mother-of-pearl is the iridescent inner layer of the shell; it is excreted as a slimy matter on the interior, and becomes hard by the deposition of carbonate of lime; it forms generally the chief part of the shell, the rough exterior epidermis being thin and dark-colored. The iridescence seems to be due to the minute undulations of the concentric layers, from whose outcropping edges the rays of light are differently refracted, or to the small folds of a single lamina; it has been successfully imitated on steel. Mother-of-pearl is familiarly known in its application to ornamental purposes, and thousands of tons of the shells are annually exported from the Indian and Pacific oceans, valued according to quality from $70 to $650 a ton; it is used principally for buttons, knife handles, inlaying of furniture, &c., and is often beautifully carved. The nacre of the genera *avicula*, *turbo*, *haliotis*, *nautilus*, and other bivalve and univalve shells, is also used as mother-of-pearl.—False or artificial pearls were formerly made at Murano, a suburb of Venice, of glass lined with a pearl-colored varnish, or with quicksilver; but the French have been of late years the most successful imitators of the natural pearl, and to such a degree of perfection have they carried the art, that only the most careful examination discloses the difference between the true and the false gem. The artificial pearls are lined with wax and fish scales, which are taken from the body of the fish while living, in order to preserve the glistening hue. The roach and dace, which furnish the scales, are supplied by the fishermen of the Seine, who derive a very considerable profit from this source. A variety of the smelt, said to be peculiar to the Tiber, has long afforded the Roman jewellers the means of coating waxen beads so that they have a greater resemblance to the real pearl than either the Venetian or French; but being external, it is much less durable. The exact process is kept jealously secret.

PEARLASH. See POTASH.

PEASANTS' WAR, a revolutionary movement in southern and central Germany, which accompanied the reformation of Luther. The peasants' war has frequently been represented as one of the effects of the religious reformation, while in fact it was merely its corollary, springing from the same cause, which, in working upon different conditions of society, produced different results. Thus, while the reformation was principally a movement of the middle classes, as they are now termed, the peasants' wars were the uprising of the lowest strata of society. Through the reformation the *bourgeoisie*, if that modern term may be allowed, strove for mastery over the nobility; while in the peasants' wars broad, universal democracy, however crude in its forms, made unsuccessful efforts to bring down the lofty and complicated structure of a social system based upon privileges and distinctions of classes. As the reformation was preceded in the 14th and 15th centuries by many unsuccessful attempts, so was the great peasants' war by isolated insurrections. In 1476 Hans Böheim, called "Johnny the Piper," proclaimed himself a prophet, and rallied the peasants of Franconia against the rule of the bishops of Würzburg. In 1492 the *Käsebrüder* (cheese boys) in the Netherlands succeeded so far as to take and hold for some time the cities of Alkmaar and Hoorn. In the following year a rising of the Alsatian peasantry against the despotism of the burghers was suppressed with the utmost cruelty. In 1502 the peasants of Swabia formed a league, known under the name of the league of the brogue (*Bundschuh*), which was promptly put down by the nobility. Another effort was made by the peasants' league of the "poor Conrad," but it proved equally unsuccessful. In 1515 the peasants of Hungary, having been called to arms against the Turks, were formed into an army by George Dózsa and levied a war of extermination against the nobility. They maintained their rule for a year, when they were vanquished by John Zápolya. Yet of all these movements no one was so well preconcerted and organized, or so well defined in its objects, as the peasants' war which ravaged a large part of Germany in 1524 and 1525. It broke out in Swabia, where the peasants, having conquered the abbey of Kempten, compelled the prince abbot to resign by treaty all rights and privileges oppressive to the peasantry. Next Diederick Hurlewagen led the peasants of the Allgau against the prince bishop of Augsburg, and within a few weeks tens of thousands of peasants rallied under the emblem of a plough wheel. Obtaining the secret support of the expelled Duke Ulrich of Würtemberg, they soon became masters of the country, and many noblemen fell victims to their hatred; no quarter was given or asked. Hundreds of castles and convents were sacked and burned. The people of the small cities and towns made common cause with the peasants; a number of noblemen even took sides with them and gave them a more perfect military organization. Wherever the news of these successes went, insurrections broke out. In Franconia over 200 castles and convents were destroyed. Thence the war extended to Bavaria, Austria, Hungary, Croatia, and Bohemia in the east, through Hesse, the Palatinate, Alsatia, and Lorraine in the west, and even to Thuringia and Saxony, where in Thomas Münzer the peasants found an enthusiastic and gifted leader. The Swabian peasants, with whom the movement had begun, proclaimed the following propositions, the attainment of which was to be the common object of the revolution: 1, the ministers should be elected by the lay members of the church; 2, the proceeds of the tithing should be applied to the support of the poor and to municipal purposes, a reasonable salary only being appropriated therefrom to the minister; 3, servitude should be abolished; 4, the exclusive privileges of princes and noblemen in regard to hunting and fishing should be abolished; 5, the woodlands appropriated by the clergy and nobility should be returned to the village corporations; 6 to 8, the socage service should be fixed by law, the ground rent reduced, and the feudal tenure regulated; 9, justice should be administered fairly and firmly according to plain written laws; 10, all fields and pasture grounds arbitrarily taken from the village corporations by the clergy and nobility should be returned to them; 11, the right of heriot shall be abolished; 12, any of the preceding articles should be null and void whenever it should be proven not to be in accordance with the Scripture. In two columns, one led by Götz von Berlichingen, the other by Florian Geyer, the peasant army marched toward Würzburg, whose citizens made common cause with them. But instead of vigorously pushing to the north and uniting his forces with those of Münzer, Götz von Berlichingen, who at heart was a traitor to the cause, which he had espoused from mercenary motives, remained inactive and gave the princes time to concentrate their armies. In April, 1525, Count Waldburg led the army of the Swabian league through Würtemberg, and defeated all detached corps of the peasants. On May 2 a column of 25,000 peasants was routed after a bloody struggle near Böblingen. When, on May 15, Münzer's army had been annihilated near Frankenhausen, and at the same time the peasants of Lorraine had been crushed in two sanguinary battles near Scherweiler and Lupstein, the war was virtually at an end. A horrid butchery followed. In the Palatinate 17,000 peasants capitulated. The duke of Lorraine pledged his princely word not to molest them on their return; yet they had scarcely laid down their arms when the soldiery was let loose upon them, and they were massacred almost to a man. The noblemen and burghers who had taken sides with them while their success seemed probable, left them as soon as the tide turned, and even joined their enemies. The Allgau peasants alone withstood the power of the Swabian league for some time longer. At last they succumbed to the greatest general of the time, George von Frundsberg. The vanquished were treated with enormous cruelty. Thousands upon thousands of prisoners were beheaded, hanged, impaled, or tortured to death. Hundreds of the inhabitants of those cities which had surrendered to the peasants shared the same fate. In Rothenburg, Weinsberg, and Würzburg especially, nearly all the prominent citizens were hanged. It is estimated that during the brief duration of the war no fewer than 100,000 or 150,000 people lost their lives. The propositions of the peasants were as violently denounced by the leaders of the reformation as ever the tenets of the communists have been by the liberals of the present day. The immediate effect of the peasants' war, like that of all unsuccessful revolutions, was a tenfold increase of the abuses against which it had been waged.—See Zimmermann, *Allgemeine Geschichte des grossen Bauernkriegs* (2 vols., Stuttgart, 1841; 3 vols., 1856).

PEAT, the spongy mass of vegetable matter composing the soil of swamps. It consists of matted roots, leaves, and stems of plants, the forms of which are sometimes distinctly preserved, and at others are lost in the mucky substance produced by their decomposition. It forms layers several feet in thickness, and in some localities repetitions of these are found at different depths, alternating with others of sand. The manner of formation of peat beds, the gradual spreading of the sphagnous growth of which they are made up, from the moist situations in which it originates, over surfaces naturally dry, and the conversion of these into swampy grounds, together with other peculiarities of these deposits, have been described in the article Bog. Reference is there also made to the immense bodies of peat in Ireland, where the material is most highly valued as a fuel. Peat also abounds in Scotland and upon the continent along the coasts of the German ocean, the waters of which by their overflow have determined its production. Its range is chiefly limited to the temperate zones, and to localities where the climate is moist, and the subsoil is impervious to water. In the southern hemisphere Darwin states that 45° marks its nearest approach to the equator. In the United States it is little known south of the state of New York; but it is met with in bogs of considerable extent in the N. part of that state, in New England, and in Canada. In the article Fuel (vol. vii. p. 781), the properties of peat for this use are briefly noticed; and it is there observed that its composition and valuable qualities are greatly affected by the variable quantities of mineral matters which it contains. This is rarely as low as 1 per cent. of the dried material, and in peat used for fuel sometimes reaches 33 per cent., and even more. The ashes consequently are often bulky, and according to their proportion indicate to some extent the relative values of different samples of peat. From the numerous analyses that have been made of them, they are found to present a general similarity of composition, the most variable ingredients being the sand of accidental mixture. Beside this they consist chiefly of silicate, sulphate, and carbonate of lime, and sulphate of iron. With these are phosphates and hydrochlorates of the same bases, and also of potash, soda, magnesia, and alumina. The ash being deducted, the carbon generally ranges from 50 to 60 per cent. of air-dried peat, as seen in the analyses presented in the article Fuel. According to Mr. W. Longmaid, the best samples contain from 70 to 75 per cent. of carbon. The more earthy varieties of peat, though poorly adapted for fuel, are often valued as manures for the sake of the phosphates and other fertilizing salts they contain; they are most advantageously employed in the preparation of composts with animal manures, and sometimes for tempering sandy or clayey soils. Other important uses of the material will be noticed after describing its varieties and manner of preparation for use.—Two sorts of peat are recognized; one in which the forms of the roots, stems, and leaves are distinctly preserved; and the other in which they are in great part or entirely lost by decomposition, and the result is a dense, fine-grained substance, of shining lustre like pitch. The former is of recent growth, constituting the upper layers of the bog, and is a spongy, elastic, and tough material, unless by drainage of the bog it becomes brittle. Its color varies from light to blackish brown, according to the extent of its decomposition. Both contain a large amount of water, which escapes as the peat is dried, leaving behind, it may be, only ¼ or ⅛ of the original weight. Both sorts are combustible, but the older peat is preferred, as by its greater density it gives out for the same bulk a greater amount of heat. Even this is rarely so heavy as the same bulk of water, only one of 27 samples examined by Sir Robert Kane and Dr. W. K. Sullivan, and described in their report in 1851, having a greater specific gravity than 1. This was an exceedingly dense peat, of conchoidal earthy fracture, from Athlone bog in Ireland. The vegetable structure was almost entirely lost, and when apparent indicated remains of *carex*, grasses, and *erica* in abundance; its density was 1.058. Another sample, of density 0.984, said to be a valuable fuel, found in Riversdale bog near Kimegad, is described as an extremely hard and compact peat with no trace of vegetable structure, and when broken exhibiting a resinous conchoidal fracture. The lightest varieties, of specific gravities 0.28, 0.323, &c., were spongy masses of almost unaltered *sphagnum* and *hypnum*, with remains of various grasses, twigs, bark, and roots. The dense compact peat appears to represent the first step in the progressive changes from vegetable substances to mineral coal.—The method of gathering peat, as practised in Europe, is first to remove the surface layer, which contains the living plants and their roots, extending to the depth of 6 inches to one foot. With a spade constructed to cut either 2 or 4 sides of a parallelogram, the material is then divided into oblong blocks, which, being raised up to the surface and spread for a while exposed to the sun and air, are afterward piled in open stacks and are thus more effectually dried. However well dried in this manner, the peat still retains from 20 to 30 per cent. of moisture. If the peat is of mucky consistence, so as not to bear handling when dried, the practice is to shovel it out from its bed, and moistening it with water cause it to be thoroughly intermixed and brought to uniform texture by the trampling of men and beasts. Being spread out in an even bed, it is marked off in rectangular shapes; and when the water has drained away from it, the blocks are cut out with a long knife and then are dried in the manner already described. When the peat is very thin and wet, it is gathered up by means of dredges, ladles, and even with instruments like a fisherman's net, formed of an iron hoop with one sharp edge, and having suspended from the other a bag of strong cloth through which water can drain. The material thus collected is kneaded in a kind of trough till it appears like mortar. This is laid upon a level flooring of hay in large cribs or troughs of 12 to 30 feet in width, the sides of which prevent its flowing away. When sufficiently drained it is trodden by women and children, who wear upon their feet flat boards 6 inches wide and 12 to 14 long. It thus becomes more solid; and when it will bear a person's weight it is well beaten with paddles, and then divided by lines into squares of 4 or 5 inches. On these lines the peat is cut into rectangular blocks, the length of which is the depth of the layer, about 8 inches. It is important that these should be pretty well dried before they are stored away, for fermentation is liable to take place in large close stacks of the moist material, and generate sufficient heat to set them on fire.—Much attention has been directed in Europe of late years to the uses to which peat is applicable, and various processes have been patented by which its value as a fuel is increased, or by which it is made to furnish a number of useful products. To render it more efficient as a fuel, it has been powerfully compressed by hydraulic machines, the blocks of peat being interlaid with matting. Its volume is thus reduced about ⅔, and its weight ⅔. The water that is expelled carries with it a portion of soluble mineral matter, that would be left behind if the water were evaporated; and thus the quantity of ash is diminished. By another process drying is effected by placing the peat in a centrifugal machine. After this it is ground to powder, and then thoroughly dried in cylinders which revolve in a heated chamber. From these, while at a temperature of about 180°, at which the tarry properties of the peat are just enough developed to cause it to cake under pressure, the powder is passed under the press, and is immediately converted into blocks, the density of which is about 1.14. Dr. Letheby reports of this fuel that it stows 71.24 lbs. to the cubic foot, while Newcastle coal stows about 49.69 lbs. It contains 9 per cent. of hygroscopic moisture, 55 of volatile matter, and 36 of charcoal, including 3.8 of ash. Being distilled in an iron retort, and the volatile products being passed through a red-hot iron tube in order to convert the paraffine and ingredients of the tar into gaseous hydrocarbons, 100 parts of peat yielded, of porous charcoal or peat coke, 36 parts; ammoniacal liquor, 18.88; thick tar containing paraffine, 5.14; and illuminating gas, 40. The illuminating power of the gas was equal only to that of 7 candles, but the quantity obtained was at the rate of about 14,000 feet per ton, which is as much as is afforded by the best Boghead cannel coal. When purified by passing it through an alkaline mixture, it was found free from sulphur, and in this respect preferable to coal gas. The qualities of the fuel are highly extolled; and one of these being its freedom from sulphur, it is well adapted for the reduction of ores, in the treatment of which the presence of this element is highly objectionable. The patentees (Messrs. Gwynne and co.) propose to apply it to this use by mixing the pulverized materials—ores, fuel, and flux—and compressing the mixture into globular masses, with which the furnace shall be charged.—The use of peat as a fuel in various metallurgic operations, as practised in Europe, is noticed in the articles CHARCOAL and FUEL, and in the former the methods of charring it are described. The calorific power of good dry peat, compared with coke of good bituminous coal, is estimated by Mallet to be as 1 to 7.61, and as equal to the conversion of its own weight of water into steam of 212° from 60°. By destructive distillation peat affords a variety of useful products, as pyroligneous acid or crude acetic acid, ammonia, volatile and heavy oils from which paraffine may be obtained, wood naphtha, inflammable gases, charcoal, tar, &c. Peat, more than other combustible bodies, favors the production of these organic compounds on account of the large amount of water in its composition, which keeps the temperature low during the distillation. The inflammable gaseous bodies may be advantageously employed to produce by their combustion the heat required for continuing the distilling operation, or for the evaporating pans or boilers. In 1849 a patent was granted for this process to Mr. Reece, and extensive works were afterward established by the Irish peat company near Athy, in Kildare, Ireland, for carrying it on. The peat is distilled in furnaces, like the ordinary blast furnaces, 32 feet 7 inches high, made perfectly tight by being encased in boiler-plate iron, and covered at top with a close conical valve and a double hopper. Air is blown in in limited quantity through three tuyères at the base. The volatile products are taken off at the top by two 12-inch pipes and conveyed into a hydraulic main 3 feet in diameter, from which the tar and other liquids flow into a tank, and the gases and vapors through series of condensing and purifying pipes and other apparatus, in which their separation is effectually completed. The charcoal is entirely consumed in the furnace. Various experiments of different chemists gave great encouragement to the company. The results of some of these trials are presented in the following table, those of Sir Robert Kane and Professor Sullivan having been arrived at by the distillation of samples of peat from different localities in Ireland, both in retorts and by combustion of a portion of the material by a blast of air, as the operation was then proposed to be conducted in the large way. There was little difference observed in the results of these two methods.

PRODUCTS OBTAINED BY THE DISTILLATION OF PEAT.

Products.	Kane and Sullivan.		Dr. Hodges.		Statement in company's prospectus.	
	per ton.	per cent.	per ton.	per cent.	per ton.	per cent.
Sulphate of ammonia	24 3/10 lbs.	1.110	22¼ lbs.	1.000	22 3/5 lbs.	1.000
Acetic acid, real hydrated	4 2/3 "	0.207	7½ "	0.828	....	...
Or as acetate of lime	6 4/5 "	0.805	....	....	nearly 15 7/10	0.700
Wood naphtha	50 1/5 oz.	0.140	63¼ oz.	0.282	66.3 oz.	0.185
Tar	58 3/4 lbs.	2.890	99⅓ lbs.	4.440	....	....
Products of the tar:						
Paraffine	2 4/5 "	0 125	....	....	8 lbs.	0.104
Oils	nearly 2 2/3 galls.	0.159	....	....	2¼ galls.	0.071

The manufactory is stated by Dr. Muspratt to have "now established itself, although it had many difficulties to contend against." The following late communication from Dr. Sullivan, however, does not give a very favorable view of the operation: "Now that a ready market exists, I have no doubt that 8 lbs. of paraffine per ton of good dry peat could be separated, especially by keeping over the summer oils until winter; in cold winters perhaps even more. Gas enough can be produced to work the factory (heating stills, &c.), but it has now been satisfactorily determined that the larger the supply of gas, the less will be the yield of tar, and *vice versa*. The yield of tar, when the temperature has been carefully attended to, has fully reached the anticipated quantity; but neither the ammonia nor the wood spirit has. The real source of profit, therefore, is the tar. Tar about 3.5 per cent., paraffine 0.13 per cent." From these conclusions it would appear that the chief value of peat is likely to depend on its employment as fuel; and as it is abundant in the northern parts of the United States, and but little esteemed, the experience of other nations with whom it is largely used merits attention. Moulded peat in small bricks, that sink in water, is supplied to Paris from several sources. It is brought from near Liancourt, a distance of 17 leagues, and sold at the rate of 20 francs for 2,204 lbs. avoirdupois. In 1855 one firm converted from 10,000 to 12,000 tons into charcoal, obtaining from 40 to 42 per cent. This sold at wholesale for 100 francs the 1,000 kilogrammes (2,204 lbs.), which was about the same value as wood charcoal. Mineral coal and wood at the same time were worth about ½ as much for the same weight In the exhibition of Paris in 1855 specimens of peat and peat charcoal prepared by different patented processes were exhibited, that were remarkable for their homogeneousness, density, and cheapness, and attracted particular attention. They were said to be economically employed for stationary steam engines, and even for locomotives.

PECAN, the name of a species of *carya*, a North American genus of trees belonging to the natural order *juglandaceæ*, representing the walnut family, and embracing many other species which produce edible and delicious-flavored nuts. (See HICKORY.) The pecan (*C. olivæformis*, Nuttall) is a slender tree with a regular trunk 60 or 70 feet high, the pinnate leaves 12 to 18 inches in length, the petioles angular; the leaflets are sessile, from 13 to 15 in number, oblong-lanceolate, acuminate, serrate, under side pubescent, terminal leaflet subpetiolate, attenuated at the base. It bears annually an abundance of sweet and flavored nuts, their husks being thin, and their shells soft and easily broken, and of a yellowish brown or ashen brown color. Michaux considers them superior in point of flavor to any of the nuts of Europe, especially in some particular varieties. The pecan grows spontaneously on river banks from Illinois southward to Mississippi. In gardens and in sheltered situations it bears the winters as far northward as the banks of the Hudson river in New York. It was introduced into France many years since.

PECCARY, a pachydermatous mammal of the hog family, and genus *dicotyles* (Cuv.), peculiar to America. In this genus the incisors are $\frac{4}{6}$; the canines $\frac{1-1}{1-1}$, not projecting beyond the lips as in the wild boar, but very much as in other mammals, small, triangular, and very sharp, the upper ones directed straight downward; the molars $\frac{6-6}{6-6}$, tuberculate; the fore feet are 4-toed, and the hind ones 3-toed, the outer accessory hoof being wanting; a mere tubercle in place of a tail; according to Cuvier, the metacarpals and metatarsals of the 2 longest toes on all the feet are united as in ruminants, but this Van der Hoeven says is far from being always the case. On the back, a few inches from the tail, in both sexes, concealed partly by the hair, is a gland which secretes a very fetid fluid; this bears a rude resemblance to a navel, and the generic name was derived from it, from δις, double, and κοτυλη, cavity. The head is broad, pointed, and rather large in proportion to the body; the ears moderate and pointed, the eyes small, the snout blunt, the legs thin and slender, and the skin covered with close, very stiff and sharp bristles. The collared peccary or Mexican hog (*D. torquatus*, F. Cuv.) is about 3½ feet in the male from snout to root of tail, the female being a little smaller; it is shorter but more compact than the domesticated hog; the hair is ringed with black and white, rather long, lightest at the tip; from each shoulder runs a more or less distinct white collar on each side of the neck. They usually go in couples or in small parties of 8 or 10, and not so often in large flocks as the next species; they prefer woods and swampy grounds, but they wander wherever food is abundant, even into the fields and enclosures of the planter, where they often commit great havoc; when attacked by wild beasts or by man, a flock will form a circle, with the young in the centre, and repel even the jaguar with their sharp teeth, in this way often killing dogs and severely wounding the hunter. The food consists of nuts, fruits, seeds, grain, roots, and whatever living thing they can find on or under the ground; they are omnivorous, though less carnivorous than the domestic hog; the flesh is white and tender, more like that of the hare than the hog, and with very little fat; when the animal is killed, it is necessary at once to cut out the dorsal gland, else the whole flesh would be tainted by its secretion and rendered unfit for food. They live in holes in trees or in the ground, or in any cavity which affords shelter; they are often very bold, attacking the traveller without provocation, and compelling him to ascend a tree for safety; a dog unaccustomed to hunting them is at once surrounded and killed. This species is found in Mexico and Texas, in the United States as far as the Red river in Arkansas, in lat. 31°, probably as far west as California, and in South America as far as Paraguay in lat. 27° S. When taken young they are easily domesticated, but do not mix or breed with the common hog; they bring forth only once a year, and one or two at a birth; they are rather sensitive to cold, and easily irritated, and manifest pleasure by a hog-like grunt. The white-lipped peccary (*D. labiatus*, Cuv.) is of a general blackish color, with the lower jaw white; it is a larger animal than the last, living in solitary forests in large troops, and is hunted by the natives for its flesh; it is found in South America, but does not associate with the other species. Travellers speak of a variety or perhaps a distinct species in Honduras, of a dirty black color with long tangled hair, going in large flocks and very ferocious when attacked; this goes by the name of warree.

PECK, a dry measure equal to ¼ bushel, or 2 gallons. Being dependent on the bushel, its exact capacity may be learned by referring to that title.

PECK, GEORGE, D.D., an American clergyman and author, born Aug. 9, 1797. He became a member of the Methodist Episcopal church in 1812, and entered the ministry in 1816. He was principal of the Oneida conference seminary from 1835 to 1839. He has been a member of 9 successive general conferences, and represented 4 annual conferences in that body. In 1840 he was appointed editor of the "Quarterly Review" and of the books of the general catalogue of the Methodist book concern, and in 1848 editor of the "Christian Advocate and Journal," which post he held until 1852, when he entered the regular work of the ministry. Dr. Peck has written "An Examination of Universalism," "The Lives of the Apostles and Evangelists," "Christian Perfection," "Rule of Faith," "Reply to Dr. Bascom on Slavery," "Wyoming, its History and Incidents," "Manly Character, Lectures to Young Men," and "Early Methodism in the Genesee Conference."

PECK, JOHN MASON, D.D., an American clergyman, born in Litchfield, Conn., Oct. 31, 1789, died at Rockspring, Ill., March 15, 1858. He received a limited education, and engaged in teaching for several winters, while he labored upon a farm in summer. In 1811 he removed to Greene co., N. Y., where not long after he united with the Baptist church. He was licensed to preach in 1812, was ordained at Catskill, N. Y., in 1813, and in 1814 became pastor of the Baptist church in Amenia, Dutchess co., N. Y. In 1816 he resigned his pastoral charge, and went to Philadelphia to study under the Rev. Dr. Staughton. In May, 1817, he was set apart as a missionary of the Baptist general convention to the West, went to St. Louis, and for the next 9 years was an itinerant missionary in Missouri and Illinois. In 1826 he visited New England and New York, soliciting aid to sustain missionaries in the West, and to assist in founding a literary and theological seminary at Rockspring. These objects were secured, and the Rockspring seminary edifice was erected on lands given by Mr. Peck. In April, 1829, he started "The Pioneer," the first Baptist journal published in the West, which he maintained for 10 or 12 years, at an annual loss to himself. In 1830 and 1831 he had charge of the seminary as principal. In 1831, in connection with the Rev. Dr. Going, he originated the American Baptist home mission society. In 1832 he published "The Emigrant's Guide," which led to extensive emigration to Illinois and other north-western states. Soon afterward he commenced the publication of a monthly Sunday school paper, with a view to promote the organization of Sunday schools in the West. In 1834 he published a "Gazetteer of Illinois." In 1835 Shurtleff college was founded by his exertions at Upper Alton, Ill., and the Rockspring seminary transferred to the new institution. Mr. Peck during the year travelled 6,000 miles, and raised $20,000 for the endowment of the college. His next effort was for the organization and endowment of a theological seminary at Covington, Ky. In 1840-'5 he took up his residence in Philadelphia as corresponding secretary and general agent of the American Baptist publication society, and having placed the society on a substantial basis returned to the West, and for the next 13 years was a pastor in various churches of Missouri, Illinois, and Kentucky, at the same time contributing largely to reviews and periodicals. During this period he wrote a life of Daniel Boone for Sparks's "American Biography," and a memoir of Father Clark, a western preacher, edited the "Annals of the West," and aided in the organization of historical societies in most of the north-western states and territories. He left a very large collection of manuscripts, mainly historical in their character. Harvard university conferred upon him the degree of D.D. in 1852.

PECTIC ACID. See Jelly.

PEDDLER, Pedler, or Pedlar, a word of uncertain origin, but probably derived in some way from Lat. *pes*, a foot, and perhaps through the French word *pied*. A peddler may be defined in law as one who travels about the country carrying with him goods for sale, usually by retail. Formerly, and in some countries at this time, a large part of the internal commerce in things of domestic use was carried on in this way. Peddling is now superseded, to a great extent, by permanent stores or shops, to which buyers come. This is the natural effect of the increase in the number of towns, or marts of trade, and of the greater facility of access to them by the improved roads of modern times. It still exists, however, and in thinly settled parts of this country may be said to flourish. In many, if not in all the states, peddling is regulated by statutory provisions, which are sometimes very stringent. They are intended to guard buyers from fraud, and also to protect the interests of regular traders. From the probable derivation of the word, it might be inferred that peddlers travelled on foot. In the United States this is not usually the case at present, as they commonly carry their commodities in a cart or wagon, which is sometimes a large one. In many of the states they are obliged to take out and pay for a license to carry on their trade.

PEDEE, Great, a river of South Carolina, which, rising in the N. W. of North Carolina, at the base of the Blue ridge, is called the Yadkin until it enters the former state near its N. E. corner. Thence it flows in a nearly S. direction, falling into Winyaw bay at Georgetown. Among its tributaries in South Carolina are Lynch's creek, and the Little Pedee, Black, and Waccamaw rivers. It is navigable for small vessels to Cheraw, about 150 m.

PEDOMETER. See Odometer.

PEDRO I. de Alcantara of Brazil, and IV. of Portugal, born in the palace of Queluz, near Lisbon, Oct. 12, 1798, died there, Sept. 24, 1834. On the invasion of Portugal by the French in 1807, the royal family fled to Brazil, which was raised to the rank of a kingdom in 1815. After the death of the queen Dona Maria I. the father of Dom Pedro became king of Portugal under the title of John VI., and in 1821 returned to that country, leaving his son as regent of Brazil. The arbitrary acts of the Portuguese cortes, which adopted measures reducing Brazil again to the rank of a colony, and commanding, among other things, the prince regent to come to Europe for his education, aroused the indignation of the inhabitants. A revolution took place, and Dom Pedro, placing himself at the head of the movement, was proclaimed protector and perpetual defender of Brazil; and the country being declared independent in Oct. 1822, he was proclaimed constitutional emperor, and on Dec. 1 was crowned. The difficulties to be encountered were, however, of the most serious character. No sooner had the resistance of the Portuguese troops been put down than rebellion broke out in the northern provinces, and at the same time the emperor was involved in a quarrel with the constituent assembly, wherein the democratic element was predominant. In 1825 Portugal recognized the independence of Brazil, and a treaty was made on terms highly unsatisfactory to the Portuguese. In 1826, the sovereignty of the province Cisplatina (Banda Oriental) being disputed between Brazil and Buenos Ayres, Dom Pedro declared war against the latter, which terminated unfavorably to his interests. His father dying in 1826, he became king of Portugal, but immediately abdicated in favor of his infant daughter, Dona Maria da Gloria, as the Brazilians feared that they were once more to be made dependent upon the mother country. The internal discontents increased; the feeling in the chamber of deputies against the emperor became of the most violent character; and at length a popular tumult in Rio Janeiro compelled him to abdicate in favor of his son, April 7, 1831, and to return to his native country. In the mean time the crown of Portugal had been usurped by his brother Dom Miguel, and Dona Maria, after a residence in England, had taken refuge in Brazil, whence she now accompanied her father to Europe with the hope of conquering her throne by his assistance. Dom Pedro landed at the island of Terceira, one of the Azores, issued a decree in favor of Dona Maria, and with the assistance of French and English volunteers began a war which terminated in 1834 by the complete success of the queen's party. (See Miguel.) On May 26 a convention was signed by which Dom Miguel agreed to leave the kingdom for ever. Dom Pedro was now appointed regent during his daughter's minority, but he died before it expired. In 1833 he had been excommunicated by the pope for confiscating monastic property in Portugal.

PEDRO II. de Alcantara, emperor of Brazil, son of the preceding, born Dec. 2, 1825. He was little more than 5 years old when his father abdicated the crown in his favor. During his minority the country was distracted by rival factions; and at length, when Pedro II. was 14 years of age, a bill was passed in the legislature declaring that he had attained his majority. On July 23, 1840, he ascended the throne, and was crowned July 18, 1841. The disturbed state of the country still continued. Several of the provinces were in arms; in that of São Paulo order was restored by Gen. Caxias; but the war was prolonged in the province of Minas Geraes until the decisive victory of the royalists at San Lucia in 1842. The subsequent reign of the emperor has been peaceful, with the exception of the war carried on against Buenos Ayres, for the independence of Uruguay and Paraguay. The troops of Brazil, Entre Rios, Corrientes, and Uruguay, under Urquiza, defeated those of Buenos Ayres under Rosas on the field of Monte Caseros. A dispute with Great Britain on account of the non-observance of the treaty regulations in regard to the abolition of the slave trade was satisfactorily settled by the prohibition of the traffic. Under his rule Brazil is steadily increasing in power, the government has been consolidated, the finances are in a good condition, and internal improvements are actively carried on. Dom Pedro possesses remarkable literary and scientific acquirements and a liberal turn of mind, and enjoys the enthusiastic affection of his subjects. On Sept. 4, 1843, he married the princess Theresa Christina Maria, daughter of Francis I., king of the Two Sicilies. He has two children, the princesses Isabella and Leopoldina.

PEDRO V., king of Portugal, born in Lisbon, Sept. 16, 1837. He is the son of Dona Maria II. and Prince Ferdinand of Saxe-Coburg, and his mother dying in Nov. 1853, he succeeded to the throne under the regency of his father. He visited England in the same year, and France at the time of the great exhibition in Paris in 1855, and also travelled in Italy, Switzerland, Holland, and Belgium. During his minority the most important transactions were the conclusion of extradition treaties with France and Belgium, and commercial treaties with the states of South America. He assumed the reins of government Sept. 16, 1855. On May 18, 1858, he married the princess Stephanie of Hohenzollern-Sigmaringen, who died July 17, 1859.

PEDRO THE CRUEL, king of Castile and Leon, born in Burgos, Aug. 30, 1334, killed March 14, 1369. He succeeded his father Alfonso XI. in 1350, and in 1353 married Blanche de Bourbon, sister of the king of France, but in three days deserted her, and devoted himself to his mistress Donna Maria Padilla, whose relatives he raised to the highest offices. Subsequently he poisoned his queen, and cruelly persecuted members of his own family and Castilian grandees, until an insurrection was raised against him under the lead of Henry of Trastamara, his natural brother, who claimed the throne. At the same time the pope excommunicated the king and laid his kingdom under an interdict. Henry was defeated and driven to France, but in 1366 revived his claim to the throne, in which he was supported by the pope and Charles V. of France. Pedro sought refuge in Bayonne, where he obtained the assistance of Edward the Black Prince, who placed him again on the throne; but disgusted with his conduct he left him to his fate, and in the battle of Montiel, in La Mancha, Pedro was defeated, and slain by the hand of his rival, who succeeded him under the title of Henry II.

PEDRO, DOM, duke of Coimbra, and regent of Portugal, born in Lisbon, Dec. 9, 1392, died May 20, 1449. He was the second son of John I. of Portugal and Philippa of Lancaster, daughter of John of Gaunt. While yet young he was intrusted with the command of the first expedition against Ceuta. He next devoted 4 years (1424-'8) to travel, visiting all the courts of Europe, and penetrating even to Bagdad, where the sultan received him with great magnificence. At Venice the republic presented him with the works of Marco Polo, which were reproduced in Portugal. After the death of Edward I. the people became discontented with the regency of the queen, who had been appointed to that office during the minority of Alfonso V. Dom Pedro skilfully fomented the dissatisfaction, and was nominated by the cortes defender and regent of the kingdom, Nov. 1, 1439. He abolished undue taxation, encouraged maritime enterprise, was the patron of letters and the arts, and himself a poet of no mean pretensions. He succeeded in bringing about a marriage between his daughter Isabella and the young king (1446). A quarrel between himself and his illegitimate brother the duke of Bragança, each claiming the dignity of constable of the kingdom, broke out into open rupture and finally into civil war. Bragança gained the king to his interest. Pedro having retired to Coimbra, but not caring to sustain a siege, advanced to meet the royal troops with a force of 1,000 horse and 5,000 infantry. The hostile armies met at Alfarrobeira, May 20, 1449, and a battle ensued, in which the regent's forces were defeated. In the thick of the fight Dom Pedro was killed by an arrow. His friend, the chivalrous Almada, was also slain. The duke's head was cut off and his body left exposed on the field, but after the lapse of 4 days was buried by the enemy in a chapel hard by, whence at the entreaty of the queen it was permitted to be removed to the family vault in the monastery of Batalha, in 1455.

PEEBLESSHIRE, or TWEEDDALE, an inland county in the S. of Scotland, bounded N. by Edinburghshire, E. by Selkirkshire, S. by Dumfriesshire, and W. by Lanarkshire; area, 319 sq. m.; pop. in 1851, 10,738. It is watered by the Tweed. The greater part of the surface consists of mountain, moor, and bog, the elevation of the first varying from 2,400 to 2,800 feet. Coal and limestone have been long wrought in various places. There are manufactories of woollens. Peeblesshire returns one member to parliament.

PEEL. I. **Sir Robert**, an English manufacturer, born at Peel's Cross, near Lancaster, April 25, 1750, died at Drayton Manor, Staffordshire, May 3, 1830. He inherited a moderate property, and in 1773 entered into partnership with William Yates, a cotton manufacturer of Bury, Lancashire, whose daughter he married in 1783. By industry, activity, boldness of enterprise, and consummate sagacity, he amassed a fortune before reaching middle life; but he nevertheless continued to conduct business as a manufacturer for many years subsequent with uninterrupted prosperity, having had, it is said, in 1803 upward of 15,000 persons in his employ. In 1780 he published a pamphlet entitled "The National Debt productive of National Prosperity;" and in 1790 he was returned to parliament as one of the members from Tamworth, a constituency which he continued to represent until 1820. In politics he was a stanch supporter of Pitt and the tories, and in 1797 he testified his loyalty and patriotism by subscribing, in conjunction with Mr. Yates, the sum of £10,000 to the "loyalty loan." During the alarm caused by the threatened invasion of the French he was active in the formation of volunteer corps, and raised among his own workmen a regiment called the Bury loyal volunteers, of which he was appointed lieutenant-colonel. In 1800 he was created a baronet. He left property, real and personal, estimated at above two millions sterling, the greater part of which, after liberal provisions for his numerous family, was settled on his eldest son. II. **Sir Robert**, eldest son of the preceding, an English statesman, born near Bury, Lancashire, Feb. 5, 1788, died in London, July 2, 1850. He received his early education under the personal superintendence of his father, and was subsequently sent to Harrow, where his industry and ambition soon placed him at the head of the school. "There were always great hopes of Peel among us all, masters and scholars," writes Byron, who was his schoolfellow, "and he has not disappointed them." At 16 he was entered a gentleman commoner of Christchurch, Oxford, and was graduated in 1808 with unprecedented distinction, being the first who ever took the honors of a double first class—first in classics and first in mathematics. Upon attaining his majority in 1809 he was returned to parliament for the Irish borough of Cashel, and entered public life as a member of the tory party. His university reputation and his father's praises drew toward him more attention than is generally paid to young men entering upon a political career; and he was wise enough during his first year of parliamentary life not to risk his prestige by any set speech, contenting himself with brief remarks on comparatively unimportant occasions. In 1810 he seconded the address in reply to the king's speech, and in 1811 was appointed under secretary of state for the colonies, a position not at that time of much prominence, but which he filled with credit. In Sept. 1812, he was appointed chief secretary for Ireland, an office then commonly bestowed upon the most promising of the youthful members of the party in power. In the then disturbed political condition of Ireland the arrival of a secretary holding the high tory principles of Mr. Peel, and opposed to Catholic emancipation, was the signal for an attack upon him, which was maintained with unwavering severity during his whole term of office. No term of reproach was considered too strong, no abuse too violent, and the ultra Roman Catholics seldom called him by any other appellation than "Orange Peel." O'Connell, who was then the popular idol of the opposition, singled him out for attack, and for the virulence of his language was challenged by Peel, who proceeded to the continent to afford his adversary a hostile meeting; but the duel was prevented by the arrest of O'Connell in London. His most important act while in Ireland was the establishment of the regular Irish constabulary, nicknamed the "Peelers," which was the first step toward the introduction of that system of metropolitan police now familiar to every considerable provincial town of Great Britain. In 1817 he was returned to parliament for the university of Oxford; and in the succeeding year he resigned his Irish secretaryship, and succeeded Mr. Horner as chairman of the bullion committee, in which capacity he introduced in 1819 the bill authorizing a return to cash payments which bears his name. It brought upon him no slight odium, and was the first political act in which his father, who still held his seat in parliament and was a stanch supporter of Pitt's currency doctrines, differed from him. In 1822 he succeeded Lord Sidmouth as home secretary, and during his term of office procured the passage of an important series of acts reforming and remodelling the criminal law. Upon the dissolution of the Liverpool ministry in 1827 he retired from office; but upon the accession of the tory government of the duke of Wellington in 1828, he resumed the seals of the home department. The agitation of the repeal of the penal laws affecting the Roman Catholics had now reached a point which compelled the ministry either to consent to the measure or to resign office; and in a speech delivered on March 5, 1829, Mr. Peel, yielding to what he considered the exigencies of the moment, proposed Catholic emancipation. The orthodox tories at once denounced him as an apostate; and upon offering himself to the electors of Oxford university, his seat for which he had resigned upon becoming a convert to emancipation, he was defeated by Sir Robert H. Inglis. He was however temporarily returned for the borough of Westbury, and in 1830 became one of the members for Tamworth, which constituency he represented until his death. During the respite which the ministry gained by their concession Mr. Peel remodelled on its present basis the London police force—a measure with which his name will ever be honorably connected. He retired with his colleagues in Nov. 1830, having a few months previous succeeded to the baronetcy and the greater part of the immense estates of his father, and for the next 4 years remained in opposition. He opposed the reform bill with earnestness and ability, but with impaired influence; and in the first session of the reformed parliament he found himself at the head of a party numbering not more than 200, but which under his guidance was developed into a compact, powerful, and well disciplined opposition. In 1834, upon the dissolution of the Melbourne ministry, he was summoned by the king from Italy to form an administration, which he undertook, although of the opinion that the time was inopportune to attempt a conservative reaction. For several months he struggled against a formidable opposition, but was obliged in April, 1835, to retire. For 6 years he remained in opposition, having within that time declined to form a cabinet, owing to the refusal of Queen Victoria to dismiss certain ladies of her household having whig connections; and in Sept. 1841, he became first lord of the treasury, with a large and well organized majority in both houses of parliament. His ministry, though formed emphatically on protectionist principles, did not hesitate ultimately to adopt free trade doctrines; and Sir Robert himself inaugurated in 1842 a more liberal financial policy by removing the duties on certain articles of import, and considerably abating them on many others, including breadstuffs and raw materials of manufacture. At the same time an income tax for 3 years was imposed, by which the government was enabled to repeal upward of £12,000,000 of indirect taxes. In 1845 this tax was renewed for 3 years; and in 1846, in view of the approach of famine in Ireland, the premier carried a total abolition of duties on breadstuffs. So great a change in the commercial policy of the kingdom brought upon Sir Robert a large degree of odium among the agricultural classes, whose interests, it was supposed, would be ruined by the repeal of the corn laws. A coalition of the protectionists and the whigs, the former led by Disraeli and Lord George Bentinck, overthrew him on the Irish coercion bill, and on June 29, 1846, he resigned office. In addition to the measures mentioned, his administration was distinguished by several of a liberal character touching Ireland, and for relieving the disabilities of the dissenters and Jews. Its foreign policy was also conducted with success in Europe and the East. On the other hand, Sir Robert did nothing to check the railway mania of 1845-'6, but rather encouraged it, as a source of prosperity. Although out of office, he still retained much influence, and his efforts tended to repeal the navigation laws and to advance the principle of Jewish emancipation. He spoke for the last time in parliament on June 28, 1850, in opposition to Lord Palmerston's foreign policy, as exemplified in the Greek question. On the succeeding day, while riding on Constitution hill, he was thrown from his horse, and died after great physical suffering in consequence of the injuries received. His death excited a universal feeling of regret. It was admitted by those who differed with him on the great political measures he successfully advocated, that no man ever undertook public affairs with a more thorough determination to leave the institutions of his country in an orderly, honest, and efficient condition; and his friend the duke of Wellington once observed of him: "Of all the men I ever knew, he had the greatest regard for truth." In private life he was honored by all classes. Of his simplicity and independence of character it is sufficient to record that he declined a peerage and the order of the garter, and left in his will a solemn injunction to his children against the acceptance of such honors. By his wife, a daughter of Gen. Sir John Floyd, he left 7 children, 5 sons and 2 daughters, all of whom survived him. III. Sir Robert, eldest son of the preceding, born in London, May 4, 1822. He was educated at Harrow school and the university of Cambridge, and entered public life in 1844 as an *attaché* to the British embassy at Madrid. Subsequently he served as secretary of legation and *chargé* in Switzerland; was a junior lord of the admiralty from 1855 to 1857; and in the latter year was present at the coronation of Alexander II. of Russia, as secretary of the special mission despatched by the British government to Moscow. He succeeded his father in 1850, and since that period has represented Tamworth in parliament. In 1856 he was married to Lady Emily Hay, daughter of the marquis of Tweeddale. IV. Frederic, brother of the preceding, born in London, Oct. 26, 1823. He was educated at Harrow and at Trinity college, Cambridge, and in 1849 was called to the bar at the Inner Temple. From Nov. 1851, to Feb. 1855, with the exception of several months in 1852, he was under secretary for the colonies, and from 1855 to 1857 under secretary for war; and since 1860 he has been one of the secretaries of the treasury. In 1859 he was returned to parliament from Bury for a second time.

PEELE, George, an English dramatist, born in Devonshire about 1552 or 1553, died probably shortly previous to 1598. He was educated at Broadgates hall, now Pembroke college, Oxford, where he took his bachelor's degree in 1577, subsequently established himself in London, and became a writer for the theatre, an occasional performer, and an intimate associate of Nash, Marlowe, and Greene. Like many of the contemporary dramatists, he shortened his life by dissipation. Six dramas by him, comprising, however, probably not more than half of his works of this class, have been collected by Mr. Dyce, together with poems and miscellaneous writings (3 vols., 1828-'39). His best play, "The Love of King David and Fair Bethsabe with the Tragedy of Absalom," is pronounced by Campbell "the earliest fountain of pathos and harmony that can be traced in our dramatic poetry."

PEER (Lat. *par*, equal; Fr. *pair*), a term originally applied, in the feudal law, to all the vassals of the same lord, because, whatever might be their relative condition, they were all equally his vassals, and bound to render their feudal service in his courts, or in war. It is now applied sometimes to those who are impanelled in an inquest for trial of any person; for they are not only peers with each other, as having equal power and an equal duty, but by the common law of England every man is to be tried "by his peers." In the United States this principle has no practical application, as all are equal in law where no one has any legal rank. In England the word is most commonly used to designate a lord of parliament, all of whom are called "the king's peers," not because they are in any sense equal with the king, but because they constitute his highest court, and, whatever may be the degree of their nobility, all, as nobles, are equal in the discharge of their official duty, as in their votes in parliament, or upon the trial of any person impeached by the commons; and all share alike in all the privileges of the peerage. (See Lords, House of, and Parliament.) The different degrees of English nobility are, in the order of precedence, duke, marquis, earl (which corresponds in English to the word count on the continent of Europe), viscount, and baron. The eldest son of the first three is usually called by his father's second title, and their other sons by the term lord prefixed to their names. These titles are called titles of courtesy, their bearers having no legal right to them. The sons of a viscount are called honorable.—In France, the word *pair* has remained in use through all the governments from feudal times, and is in use now; but the functions and privileges of the peerage have varied very much at different times, the term being destitute of the definite meaning which it has attained in England. Louis XVIII. in 1814 established a house of lords, or more accurately a peerage, in some degree resembling the English system; but Villèle, the minister of Charles X., created at one time 76 new peers, when he wanted them for a political purpose.—A peeress is a woman who is noble by descent, by creation, or by marriage. A peeress by descent or by creation retains her title and nobility in law, although she marries a commoner; but a peeress by marriage loses her nobility by her marriage with a commoner, but commonly retains her title in society as a title of courtesy. It is one of the privileges of the peerage of the realm not to be liable to arrest for debt. This rule applies equally to peeresses, who are peers of the realm, and can only be tried by their peers, although they cannot sit in parliament or on trials.

PEET, Harvey Prindle, LL.D., an American instructor of the deaf and dumb, born in Bethlehem, Litchfield co., Conn., Nov. 19, 1794. His father was a farmer. At the age of 16, and for 5 winters subsequently, he taught a district school, and was afterward an assistant instructor in private academies. In 1816 he went to Phillips academy, Andover, Mass., fitted himself for college, supporting himself entirely by his own exertions, entered Yale college in 1818, and was graduated in 1822. It was his purpose to study theology, but he accepted an invitation to engage as an instructor of the deaf and dumb in the asylum at Hartford, where he was soon appointed steward. In 1831 he was appointed principal of the institution for the deaf and dumb at New York. For some years he was principal, superintendent or steward, teacher, and chaplain, as well as secretary of the board of directors, and managed all the details of the institution alone. He appealed to the legislature for the extension of the advantages of instruction to all the poor deaf mutes of suitable age in the state, and visited with a class of pupils the principal cities and villages of the state, exhibiting the success of his method of instruction. The want of suitable books for elementary teaching of the classes led him to prepare a series which are now in general use in the institutions for deaf mutes in this country, and to some extent in Great Britain. He also investigated the modes of instruction adopted in other countries, and particularly the instruction in articulation in Germany. He was a contributor to the "American Annals of the Deaf and Dumb" from its commencement, and is now one of its directors. From 1845 to 1859 he was president of the institution in New York, retaining his position as principal, which he still holds. In 1851 he visited Europe with three of his pupils, and made a careful examination of the principal deaf-mute institutions of England and the continent. He received the honorary degree of LL.D. from the regents of the university of the state of New York in 1849. In addition to the "Course of Instruction" and the "Scripture Lessons," he is the author of a great number of works on the education of the deaf and dumb.

PEET-WEET, a common name of the spotted sandpiper (*tringoides macularius*, Gray), derived from its note.

PEGASUS, in Grecian mythology, a winged horse which sprang from Medusa when Perseus struck off her head for having intercourse with Neptune. His place, according to the most ancient writers, was in the palace of Jupiter, whose thunderbolts he carried; but later authors place him among the stars as the horse of Aurora. When Bellerophon was endeavoring to kill the Chimæra, Minerva gave him a golden bridle with which he caught Pegasus, and having slain the monster by his means, endeavored to rise upon his back to heaven; but Jupiter sent a fly to sting the horse, and caused the rider to be thrown. When Mt. Helicon rose heavenward with delight at the singing of the Muses, Pegasus by advice of Neptune stopped its ascent with a kick; and on the spot where his hoof touched the ground there sprang up Hippocrene, the inspiring well of the Muses. In the later writers Pegasus is known almost exclusively as the horse of the Muses.

PEGU, a British province of Indo-China (Further India), on the E. side of the bay of Bengal, bounded N. by the Burmese empire, E. by the Tenasserim provinces, S. by the gulf of Martaban, and W. by the province of Aracan and the bay of Bengal, extending from lat. 15° 40' to 19° 30' N., and from long. 94° 11' to 96° 55' E.; extreme length 240 m., breadth 170 m.; area, 32,300 sq. m.; pop. 570,180. The most important towns are Rangoon, Martaban, Pegu, and Prome. The whole province is intersected by branches of the Irrawaddy, which flows S. from Burmah, and enters the gulf of Martaban by an extensive delta, affording several good harbors. The Sitang forms the E. boundary line; and both these rivers are navigable by vessels of considerable size to distances far beyond the limits of Pegu. The Youmadoung mountains extend along a great part of the W. frontier, but the surface in other directions is level or undulating. The minerals include iron, tin, lead, and several kinds of precious stones. The climate is warm and moist, but is not considered unhealthy. The soil is remarkably fertile, and vegetation is luxuriant. Much of the surface is covered with forests, and agriculture has been neglected, land that was cultivated formerly being now overrun with jungle. The principal productions consist of rice, timber, particularly teak, gums, ivory, and various woods used in dyeing.—Pegu was formerly an independent kingdom, but after a series of contests, extending over many ages, it was conquered by the Burmese assisted by the Portuguese. The Peguans revolted about the middle of the 18th century, subdued the Burmese, and made their king prisoner. A long series of wars followed, in which the Burmese were assisted by the English and the Peguans by the French; and the former at length became masters of the country. In 1824 war broke out between the British and Burmese, and among other provinces Pegu was conquered, but restored at the conclusion of hostilities in 1826. The imprisonment of the master of a ship, and some other British subjects, by the governor of Rangoon, led to a second war in 1852, which resulted in Pegu being annexed to the English possessions in India. (See BURMAH.)—PEGU, a town in the above described province, is situated on a river of the same name, which falls into the Irrawaddy 58 m. N. E. from Rangoon; pop. about 10,000. The streets are broad and regular, and paved with bricks, and the houses are built of wood and elevated on posts. There is a remarkable pagoda, shaped like a pyramid, built of brick of an octagonal form at the base, each side measuring 162 feet. Pegu is said to have formerly contained 150,000 inhabitants, but it was utterly destroyed by the Burmese in their final triumph over the country in 1757. It has since been rebuilt, and the population is fast increasing. It was captured by the British in June, 1852.

PEI-HO, or NORTH RIVER, a river of China, which rises in the highlands of Mantchooria, about lat. 40° 30' N., long. 112° 20' E., and after a very circuitous but generally E. course of 350 m. flows into the gulf of Pe-che-li in lat. 38° 30' N., long. 117° 47' E. Near the mouth of the river are the villages of Ta-ku and Si-ku, and a little higher up Tang-ku; but the most important town on the Pei-ho, and the largest port N. of Shanghai, is Tien-tsin at the junction of the grand canal, about 70 m. from the sea. Tung-chau, where all the boats land their passengers and cargoes for Peking, is situated 110 m. higher up, or by the sinuosities of the river 180 m. from Ta-ku. The principal tributaries of the Pei-ho are the Hoen-ho, Tsya, Chu-lung, and Tung-hui; upon the last named, 13 m. from the main stream, Peking is situated. The velocity of the stream, arising from the great altitude of its source, has scoured out a narrow channel through the deep alluvial plain of Pe-che-li, and cut into the substratum of clay beneath it. For the last 5 m. of its course the plain is little if at all above the level of high water at spring tides, and the current consequently becomes much weakened and the river discharges itself over an extensive bar. This bar is formed of tenacious clay, and the distance at low water from a depth of 10 feet without to 10 feet within is nearly 4½ m. In the channel leading over the bar there is a depth of 11 feet at high water; but at low water there is only 24 inches in most places, and extensive dry mud banks on either hand. Within the bar the channel winds upward for about a mile between steep mud banks, which are covered at high water, and render navigation at that time very dangerous. At this distance the banks become covered with reeds, the breadth is about 100 yards, and the current runs from 2 to 3 m. per hour. Forts and earthworks have been erected upon natural or artificial mounds with an altitude of from 10 to 12 feet at high water, and, from the peculiar configuration of this reach, face and flank it on all sides.—The mouth of the Pei-ho was the scene of an engagement between English and French gun boats and land forces and the Chinese on May 19, 1858, in which the Chinese were defeated. Another attack was made on the forts, June 25, 1859, by 11 English gun boats, manned by 500 men, with 700 marines, when the English were repulsed with a loss of 89 killed and 345 wounded. On Aug. 21, 1860, the attack was renewed with an English and French fleet of 200 sail and a land force of 25,000 men. The Chinese fortifications were captured and destroyed. The English lost 19 killed and 182 wounded; the French, 30 killed and 100 wounded; the Chinese loss was estimated at 3,000.

PEINE FORTE ET DURE. Formerly, in England, when a prisoner indicted for a capital felony or petit treason stood mute, as the phrase was, upon his arraignment, that is, refused to plead and so to put himself upon his trial in the mode which the law prescribed, answering either not at all, or impertinently, to the charge preferred against him, he was condemned to the punishment of *peine forte et dure.* This was the penalty of his contempt in refusing to submit himself to the legal form of trial. It wrought a forfeiture of goods, but no attainder and corruption of blood, and, therefore, no escheat of lands. The *peine forte et dure* was an infliction of extreme severity. The books of entries and other old books of the law, varying only slightly in the description of the punishment, agree that the prisoner was carried back to prison, and laid in some low, dark room, almost naked, upon his back; his body was burdened with very heavy weights; he received once each day portions of the meanest bread and water, of bread one day and of water the next, and so on alternately; and thus he continued until he died. In early times, it is supposed, the torture lasted only until the prisoner declared himself willing to plead; but later, says Hawkins, he could not save himself, if once the punishment had been ordered. Women were subjected to the same torture.—It is matter of dispute how and when *peine forte et dure* was introduced; whether it existed at common law, or was created by legislative provision. The statute Westminster the first, c. 3, which was enacted in the time of Edward I. (and there is no mention of this penalty before that reign), says that felons standing mute shall be put in *prison forte et dure;* and as it does not explain these words at all, it seems to imply that their meaning was already familiar in practice. Sir Edward Coke contends therefore that the punishment was known before the statute; that by no construction of the words of the act, *prison forte et dure*, could judges have framed so rigorous a sentence as that which we have just described; and as there is confessedly no other statute to which it can be referred, it must be presumed that it existed at common law. Sir Matthew Hale adopts this opinion, and Hawkins seems also to assent to it. It may be suggested in behalf of this view, that the author of Fleta and Britton, both of whom wrote near the time of the above named statute and commented on it, do not refer to it the origin of the *peine forte et dure*, nor give indeed any particular prominence to the similar words of the act, though it is highly probable that they would have done so if this statute had created this, in any age, remarkable penalty. On the other hand, Blackstone thinks that the punishment had a statutable origin. He urges that neither Bracton nor Glanvil, nor any other ancient author previous to Edward I., makes mention of it, and in fact traces its introduction to the language of the statute of Westminster the first. He concludes, however, that this requires imprisonment only, and says that the practice of loading the felon's body with weights was a purely merciful device, which had gradually established itself between the reigns of Edward III. and Henry IV., and was designed to deliver the prisoner the sooner from his sufferings. The penalty of *peine forte et dure* was not abolished until the 12th year of the reign of George III. (1772).—At common law a refusal to plead to an indictment of felony saved the accused from the form of trial, and therefore from conviction and its consequences, corruption of blood and escheat of his estate; and it was for the purpose of extorting a plea and of securing their escheats and forfeitures, that the feudal lords devised this penalty of a cruel death. Generally, no doubt, the device accomplished its end; though there were instances of persons who suffered death in this mode in order to preserve their estates to their families. The statute 12 George III., c. 20, prevented further need of this harsh coercion, by providing that, if any person thereafter should stand mute on his arraignment, he should be convicted of the felony charged, and judgment and its consequences should follow in the same manner as if such person had been convicted by verdict or confession of the felony charged against him.—The only instance, so far as we are aware, in which *peine forte et dure* has been inflicted in this country, was when in Massachusetts, in 1692, Giles Cory, an old man of 80 years and the husband of a reputed witch, stood mute upon his trial, and was condemned to be pressed to death.

PEIPUS, Lake, or **Tchudio Lake**, a lake of European Russia, bounded by the government of Esthonia, St. Petersburg, Pskov, and Livonia; extreme length 100 m., breadth from 15 to 35 m.; area about 1,500 sq. m. The southern part is connected with the northern by a strait, and is sometimes called Lake Pskov, the town of that name being situated at its S. E. extremity. There are several small islands at both ends of the strait. Peipus receives the rivers Embach and Kosa from the S. W., and the Tcherna and Yaetsha from the E. and S. E; and the Narva flows to the gulf of Finland from the N. E. end. The shores are low and marshy, and the greatest depth is about 60 feet.

PEIRCE, Benjamin, LL.D., an American mathematician, born in Salem, Mass., April 4, 1809. He was graduated at Harvard college in 1829, and after teaching for two years in the Round Hill school at Northampton, was appointed tutor in mathematics at Cambridge in 1831, university professor of mathematics and natural philosophy in 1833, and Perkins professor of astronomy and mathematics in 1842. He still holds the last office, as also that of consulting astronomer to the "American Ephemeris and Nautical Almanac," to which position he was appointed upon the establishment of the almanac in 1849. He is a member of the leading scientific societies of the United States, and was elected an associate of the royal astronomical society of London in 1849; member of the royal society of London in 1852;

president of the American association for the advancement of science for the Cleveland meeting in 1853; and one of the scientific council which established the Dudley observatory in 1855. The mathematical powers of Prof. Peirce were prominently manifested in early life. He was a pupil of Dr. Bowditch, and the proof sheets of the translation of the *Mécanique céleste* passed under his scrutiny and supervision before going to the press. When the late Mr. Gill edited the "Mathematical Miscellany," Prof. Peirce was among the most efficient contributors. Afterward he himself undertook the publication of the "Cambridge Miscellany of Mathematics, Physics, and Astronomy," of which however only 5 numbers appeared. It was in this that he gave his celebrated and exhaustive discussion of the motion of a top spinning upon a plane surface. A series of text books on the different branches of mathematics, prepared by Prof. Peirce during the years 1836–'46, attracted the attention of scientific men by their originality, and the singular power of generalization and condensation which they displayed. The return of Encke's comet in 1842, and the appearance of the great comet of February and March, 1843, served as an opportunity for Prof. Peirce to attract public attention to the need of a well furnished observatory for the college, and to his efforts the movement was due which resulted in the establishment of the present well endowed institution. The first of his investigations which may be said to have compelled the notice of scientific men throughout the world was his criticism of the computations and results of Leverrier, upon which this geometer based his demonstration of the existence and place of the unknown planet to whose attraction the irregularities observed in the motions of Uranus were to be attributed. In the face of the striking accordance between the direction of the planet predicted by Leverrier, and that of the planet Neptune discovered by Galle, searching at Leverrier's request, Peirce boldly announced to the American academy that the planet Neptune did not accord with the computations of Leverrier, and declared that its true position in space and its movements were incompatible with them. A statement apparently so improbable attracted great attention and severe criticism. It is related that Mr. Edward Everett, being present at the meeting, actually addressed the academy upon the subject, and begged that so utterly improbable a declaration might not go out to the world with the academy's sanction. "It may be utterly improbable," retorted Peirce, "but one thing is more improbable still, that the law of gravitation and the truth of mathematical formulas should fail!" Prof. Peirce followed up his announcement by a thorough discussion of the mutual influences of Uranus and Neptune, which, in conjunction with the computations of Walker, soon placed the theory of the new planet upon a firm basis. The fluidity of Saturn's rings was discovered and announced by Peirce in 1851, and demonstrated from purely analytical considerations. In the full demonstration, which for peculiar reasons he withheld for two years, he established the important fact that no ring is capable of sustaining itself in stable equilibrium about a primary without the support afforded by the attraction of satellites properly situated for the purpose, nor under any circumstances if solid. During the following year Prof. Peirce prepared a volume of lunar tables for the use of the American "Nautical Almanac." Though founded upon the general theory of Plana by the employment of coefficients in a manner empirical, and only intended by the author to serve a temporary purpose until the long expected tables of Hansen should appear, they still represent the observed places of the moon with such precision, that they are yet (1861) employed in the almanac office as the basis of all the computations into which the place of the moon enters. Detailed comparisons of the errors of these tables with those of Hansen's, as determined by actual observation, have been published in the "Astronomical Journal," and show that the accordance of Peirce's tables during the last 13 years is quite comparable with that of the tables which Hansen had obtained from 10 years of profound research. In 1857 appeared Peirce's "Treatise on Analytic Mechanics" (4to.), designed to form one of a series of 4 treatises, the others being respectively upon "Celestial Mechanics," "Potential Physics," and "Analytic Morphology." As one of the scientific council of the Dudley observatory, he took an active part in the struggle in 1858 between that body and the trustees of the institution, and in conjunction with Professors Bache and Henry published the defence of the director of the observatory. Among the discoveries and important investigations of Prof. Peirce, are especially to be named his theory of the tails of comets, published in the "Astronomical Journal," showing the mode and laws of their formation; his methods of investigating terrestrial longitudes and the form of the moon's limb by means of occultations of the Pleiades, published in the report of the superintendent of the coast survey; his researches upon personal equation, showing the existence and means of measurement of a new and before unrecognized form of personal error, in observations "by eye and ear," arising from the proneness of every individual to award an undue prominence to particular fractions of the second; and the singular and valuable "Criterion for the Rejection of Doubtful Observations," by means of which the propriety of exclusion of specially discordant observations from a series, is definitely determined in each individual case by the mathematical laws of probability, and removed from the arbitrary or uncertain judgment of the computer. He has also investigated the forms of equilibrium of an elastic sack containing a fluid, researches which conducted him to his favorite theory of analytic morphology; the phyllotactic series of numbers; and the curious and elegant cyclic solution of the celebrated "school-girl puzzle," to which problem its author had found no symmetrical solution whatsoever. Prof. Peirce received the degree of LL.D. from the university of North Carolina in 1847.

PEIRCE, Bradford K., an American clergyman, and founder of a reformatory school for girls, born in Royalton, Vt., Feb. 3, 1819. He was graduated at the Wesleyan university, Middletown, Conn., in 1841, and in 1842 was received as a Methodist minister into the New England conference, and stationed at Waltham, Mass. He was subsequently transferred to Newburyport, Charlestown, and Boston. His health failing, he received a local relation, and spent the next 10 years in Roxbury, Mass. During this period he prepared a series of biblical question books for Sunday schools, a "Bible Scholars' Manual," a "Commentary upon the Book of Acts," and several small books for Sunday schools. He also published a volume entitled "The Eminent Dead," which had a very large sale. In 1850 he was appointed agent for New England of the American Sunday school union. In 1855 and 1856 he was elected state senator from Norfolk co. He now entered heartily into a movement for establishing a reform school for girls, and when it was organized, under the name of the state industrial school for girls, at Lancaster, Mass., was appointed (March, 1856) superintendent and chaplain of the institution, a position which he still holds. The school was opened Aug. 26, 1856, under a plan proposed by Mr. Peirce. It is exclusively for girls, between the ages of 7 and 16, who have been guilty of petty crimes, or are exposed to the danger of a vicious life. They are examined by a board of commissioners appointed by the governor, having been committed on the warrant of a judge of probate. They are divided into families of 30, each under the care of a matron and two assistants. On the grounds, which comprise about 80 acres, there are 4 "homes," and a chapel and residences for the superintendent and the farmer. There are no walls or high fences, the restraints being wholly moral. Corporal punishment is not permitted, and the whole management is that of a well ordered family. It has been thus far successful, more than 100 girls having been sent out into society completely reformed.

PEIRCE, Cyrus, an American teacher, born in Waltham, Mass., Aug. 15, 1790, died in West Newton, Mass., in May, 1859. He was graduated at Harvard college in 1810, and immediately afterward took charge of a private school in Nantucket, where he taught for 2 years. He then returned to Cambridge, and studied theology for 3 years, after which he resumed his school at Nantucket. In 1818 he commenced preaching, and in the following year was settled as minister of a Congregational church at North Reading, Mass., where he remained for 8 years. He felt, however, that teaching rather than preaching was his vocation, and at last withdrew from the ministry, and in connection with a relative, Mr. Simeon Putnam, opened a school at North Andover. In 1830, in compliance with repeated solicitations, he returned to Nantucket, and for 6 years managed a large school with hardly a resort to the use of the rod, but with the most perfect order and success. By his urgent advice and in accordance with a plan devised mainly by him, the public schools of Nantucket were reorganized upon a thorough system of gradation, embracing primary, intermediate, and grammar schools, and a high school. Of this last he became the principal in 1837. In 1839 he was chosen principal of the normal school just founded at Lexington, Mass., the first institution of the kind established in America. The duties of this position proved too arduous for his health, and at the end of 3 years he was obliged to resign. After 2 years of rest he took charge of the female normal school, now removed from Lexington to West Newton. In 1849 he was again compelled to resign, and made a voyage to Europe, his friends and pupils having raised a purse of $500 to defray his expenses. After his return in 1850, his health being partially restored, he became an assistant in a school at West Newton, and there continued to teach till near the close of his life. He published a "Letter on Normal Schools," addressed to the Hon. Henry Barnard (1851), and a prize essay on "Crime, its Cause and Cure" (1853).

PEIRESC, Nicolas Claude Fabri, seigneur de, a French scholar, born in Beaugensier, Provence, in 1580, died in Aix in 1637. He travelled in Italy, Holland, and Great Britain, became acquainted with most of the scientific and literary men in those countries, and extended his researches to nearly every branch of human learning. He possessed a large fortune, which he applied to the patronage of scholars and men of letters, and the collection of books, antiquities, and works of art. Scaliger, Salmasius, Holstenius, Kircher, Mersenne, Grotius, and Valois were the recipients of his liberality. He devoted much attention to natural history, and imported into France several species of plants and trees. Although he published nothing, he was deservedly styled by Bayle the "procurator-general" of literature. Science is indebted to him for valuable observations and discoveries; he declared previous to Cuvier that fossil bones, which were considered remains of giants, belonged to well known animals. His death was almost universally mourned; the Roman society of "Humorists" alone published poems in his honor in no fewer than 40 different languages. Out of his voluminous correspondence, his letters to Holstenius are perhaps of the greatest interest. They may be found in Boissonade's *Holstenii Epistolæ ad Diversos* (8vo., Paris, 1819). His life was written in Latin by Gassendi (4to., Paris, 1641; translated by Rand, London, 1657).

PEKING, or PEKIN (Chinese *Pe-King*, northern capital), the capital of the Chinese empire and of the province of Chi-li, situated on the river Tung-hui, a small tributary of the Pei-ho, in lat. 39° 54' N., long. 116° 27' E., about 12 m. from the Pei-ho, 40 m. from the nearest part of the great wall, and 100 m. N. W. from the gulf of Pe-che-li; pop. about 2,000,000. It stands on an extensive sandy plain, and consists of two parts, Nui-ching, the Tartar city, to the N., and Wai-ching, the Chinese city, to the S. The Chinese city is a parallelogram in outline, with an area of 15 square miles; the Tartar city, which adjoins one of the longer sides of the other, is about 3½ miles square, or 12 square miles in area. Both these divisions are enclosed by walls about 50 feet high, 25 feet thick at the base, and 12 feet at the top. The walls consist, for the most part, of earth or rubbish, faced with stone or brick, laid in very durable cement composed of clay and lime. They are smooth, but not quite perpendicular on the outside, and on the inside the bricks *recede* one above another like steps; and there are sloping embankments at intervals to enable horsemen to ascend to the top. Square towers project 40 or 50 feet from the outside at distances of about 60 yards; and in some places there are ditches. Outside the walls there are several suburbs, and extensive earthworks upon the E., N., and W. sides of the Tartar city, the whole being nearly 25 m. in circumference. Upon approaching Peking, very little is seen of the buildings inside, and the principal relief to the monotony of the dead wall is the watch towers over the gates, the flag staffs in pairs before the different official residences, a few pagodas, and the tops of large clumps of trees. The cities are entered by 13 external gates; and there are 3 which open from the Tartar city into the Chinese. These gates are formed by arches, each surmounted by a wooden tower generally 5 stories high, with embrasures in each story closed by shutters upon which are painted bull's eyes that at a little distance have the appearance of guns. The gates are further defended by a semi-circular rampart in front of each, with towers at the ends, so that the entrance is from the sides and not from the front of the gate. The Tartar city consists of 3 enclosures, one within another, each surrounded by its own wall. The innermost contains the imperial palace and its surrounding buildings; the second is occupied by the several offices appertaining to the government, and by many private residents who receive special permission to reside within its limits; and the outer one, for the most part, consists of dwelling houses, with shops in the larger avenues.—The inner area is called Kin-ching, or prohibited city, and its circumference is about 2 m.; the wall is nearly as solid as that around the city, and is faced with glazed bricks and coped with yellow tiles. It is entered by 4 gates, each surmounted by a tower, which, with one in each corner, afford quarters for the troops and guard. The interior of this enclosure is divided into 3 parts by walls running from N. to S., and the whole is occupied by a suite of court yards and apartments which are superior to any other buildings of the kind in China. The S. gate, called Meridian gate, leads into the middle division, in which are the imperial buildings. It is reserved for the use of the emperor, and when he passes through it a bell and gong placed in the tower above are struck. When his troops return in triumph, the prisoners they bring are here presented to him; and here the presents he confers on vassals and ambassadors are bestowed with great pomp. Passing through this gate into a larger court, over a small creek spanned by 5 marble bridges which are ornamented with sculptures, a second court is entered, paved with marble and terminated on the sides by gates, porticos, and pillared corridors. At the head of this court is a superb marble structure 110 feet high, called the "gate of extensive peace." It is a sort of balcony where the emperor, on New Year's day, his birthday, and other occasions, receives the homage of his courtiers assembled in the court below; 5 flights of stairs decorated with balustrades and sculptures lead up to it, and 5 gates open through it into the next court yard. Beyond it are two halls, one where his majesty examines the implements used in the annual ploughing, and the other where he feasts his foreign guests and other distinguished persons on New Year's day. After ascending a stairway and passing another gate, the Kien-Tsing-kung, or the "tranquil palace" of heaven, is reached, into which no one can enter without special permission. In it is the council chamber, and here candidates for office are presented to the sovereign. It is the loftiest and most magnificent of all the palaces. Beyond it stands the "palace of earth's repose," where the empress rules her miniature court in the imperial harem; and between this and the N. wall of the prohibited city is the imperial flower garden, designed for the use of its inmates. The gardens are adorned with elegant pavilions, temples, and groves, and interspersed with canals, fountains, artificial lakes, and flower beds. In the E. division of the prohibited city are the offices of the cabinet and the treasury. North of these is the "hall of intense thought," where sacrifices are offered to Confucius and other sages; near this is the library, a catalogue of the contents of which is published from time to time. At the N. end of the E. division are numerous palaces and buildings occupied by princes of the blood and their connections; and in this quarter is situated the Fung-sien-tien, a small temple where the emperor comes to bless his ancestors. The W. division contains a great variety of edifices devoted to public and private purposes, among which may be mentioned the hall of distinguished sovereigns, statesmen, and literati, the printing office, the court of comptrollers for regulating the receipts and disbursements of the court, and the Ching-hwang-mian, or guardian temple of the city. The number of people within the prohibited city is not very great, and most of them are Mantchoos.—The second enclosure, which surrounds the one just described, is called Hwang-ching, or imperial city, and is of oblong form about 6 m. in circuit. It is enclosed by a wall about 20 feet high, entered by 4 gates, and none may pass through them without special permission. From the S. gate, called the "gate of heavenly rest," a broad avenue leads up to the prohibited city; in front of it, outside the wall, is an extensive enclosure having an entrance from the S. which no one is permitted to pass through except on foot. On the right of the avenue within the imperial city is a large collection of buildings surrounded by a wall, where offerings are presented before the tablets of deceased emperors and empresses, and worship is performed by the members of the imperial family and clan to their departed forefathers. Upon the opposite side of the avenue is the altar of the gods of the land and grain, where in spring and autumn the emperor alone makes offerings to these divinities, who are supposed to have been originally men. On the E. side of the imperial city, N. of the great temple, and not far from the E. gate of the prohibited city, is a depository of military stores, with workshops for their manufacture. The establishment of the Russian college lies N. of this gate; and in the N. E. part of this side are the residences of the lamas, with numerous temples, monasteries, and other religious edifices. Much of this quarter is occupied by dwelling houses and by temples dedicated to various inferior gods in Chinese mythology. On the N. side, surrounded by a wall more than half a mile in circuit, is the King-shan, or artificial mountain, about 150 feet high, with 5 summits, each of which is crowned by a pavilion. Various kinds of trees border its base and line the paths leading to the tops, and the enclosure is enlivened by the presence of numerous animals and birds. The W. part is chiefly occupied by a park, in and around which are found some of the most beautiful spots in the metropolis. An artificial lake, more than a mile long, and with an average breadth of 220 yards, occupies the centre. It is crossed by a marble bridge of 9 arches, and its banks are shaded by groves of trees under which are well paved walks. There are many artificial hills of rock-work, groves, gardens, and parterres of flowers. On the S. E. side of the lake is a large summer house consisting of several edifices, partly in or over the water. On the W. side is the hall for the examination of military candidates, where the emperor in person witnesses their exhibitions of equestrian archery. At the N. end of the lake is a bridge leading to an islet, the centre of which presents the aspect of a hill of gentle ascent covered with groves, temples, and summer houses, and surmounted with a tower from which an extensive view of the metropolis is obtained. Near the N. E. end of the park is a temple dedicated to Yuenfi, the reputed discoverer of the silkworm, near which a plantation of mulberry trees and a cocoonery are maintained for the preparation of silk. In the neighborhood of the "temple of great happiness," and not far from the preceding, on the borders of the lake, is a gilded copper statue of Buddha, 60 feet high, with 100 arms.—The third or outer enclosure surrounding the imperial city is called the Tartar city, and consists of several wide streets crossing each other at right angles. The principal government offices are situated along the avenue leading S. from the imperial city to the Chinese city. Several boards have their bureaus on the E. side; the board of punishments, with its subordinate departments, has its courts on the W. side, and the censorate stands immediately S. of it. The astronomical board, the medical college, the national academy, and the colonial office are also on this avenue. Near the colonial office is the temple where the nearest ancestors of the reigning family are worshipped by his majesty and the princes of his family on the first day of every month. The temple is pleasantly situated in the midst of a grove, and the large enclosure around it is prettily laid out with trees and shrubbery. The observatory stands in the S. E., partly upon the wall. It was at one time superintended by the Roman Catholic missionaries, but is now confided to the care of Chinese astronomers, whose predecessors were instructed by them. Close to it is the hall of literary examinations, where the candidates of the province assemble to write their essays. The Russian church of the Assumption is in the N. E. corner, and near it is the splendid "temple of eternal peace" belonging to the lamas. The lamas have about 200 Chinese and Mantchoo pupils under their care, who learn the Thibetan language; and a similar college for the Chinese and Mantchoo languages stands near the temple. The Tartar city is under the control of the general of the nine gates, who is responsible for the peace and good order within its limits; the post is conferred only on Mantchoos. Near his establishment, or headquarters, which lie about half way between the imperial city and the N. wall, is a high tower containing an immense bell and drum which announce the hours of the night. This tower is higher than those over the gates, and is one of the most conspicuous objects seen when approaching the city; and the bell is said to weigh 120,000 lbs. A large number of Mohammedans reside near the S. W. corner of the imperial city, where they have a mosque. Their ancestors were brought from Toorkistan about a century ago, and all Mohammedans visiting Peking resort to the quarter where they reside. South of the mosque stands the "church of heaven's Lord," with a convent attached to it, which the Jesuits and Portuguese built during the time of their influence. It was the finest specimen of architecture in the place, but is now going to decay. There are thus religious edifices in the Chinese metropolis appropriated to many forms of religion; to the Greek and Latin churches, Islamism, Buddhism in its principal forms, rationalism, ancestral worship, and state worship, and temples dedicated to Confucius and other deified mortals, beside a great number in which the popular idols of the country are adored. Among them is the temple where the tablets of the kings and emperors of former dynasties are collectively worshipped, with the exception of a few who have been excluded on account of their wickedness. Near this is the white pagoda temple, so called from a costly obelisk near it erected by Kublai Khan in the 13th century, and rebuilt and exquisitely ornamented in 1819. This temple contains a scab taken from the forehead of Buddha, caused by his constantly knocking his head on the ground in worship; and around the edifice are 108 small pillars on which lamps are burned in his honor. Outside of the city on the E. is the "temple of heaven," which covers a large area and is surrounded with many spacious buildings; on the W. is a corresponding structure called the "temple of earth;" both of these are connected with the state religion.—The southern or Chinese city is more populous than the Tartar, but it contains few edifices of importance, is not so well built, and the walls are not so solid. The principal streets are more than 100 feet wide, and extend between gates at opposite sides of the city; but those which branch off from the chief thoroughfares are mere lanes. They are all unpaved, and according to the state of the weather are either knee-deep with mud or covered with dust. The houses are built of brick, and seldom exceed one story in height. They are roofed with tiles of many colors; and most of the private residences have a parapet wall in front, upon which pots containing flowers and shrubs are placed. In the back streets the edifices have a miserable and squalid appearance, but in the principal thoroughfares many of them, particularly the shops, are highly ornamented with painting and gilding. The shops are open in front, and the goods are exposed in heaps outside the doors. At each side of the establishment there is generally a wooden pillar or signboard, higher than the housetop, bearing inscriptions in gilt letters setting forth the superior qualities of the wares and the probity of the dealer. Flags and streamers are hung out from these posts, and lanterns of different material and form are arranged with great ingenuity and taste. Notwithstanding the breadth of the main streets, they are much obstructed by the wares exposed outside the shops, and the number of occupations that are carried on in tents and in the open air in movable workshops. This crowd and bustle, however, is wholly confined to the principal thoroughfares, and the lanes and cross streets are perfectly quiet. Where the main streets intersect, monuments of very curious appearance, bearing some resemblance to triumphal arches, are erected in honor of distinguished individuals. Upon the E. side of the avenue which leads from the S. gate of the Tartar city and adjoining the outer gate stands the altar to heaven, in an extensive enclosure. The altar is a round terrace consisting of 3 stages each 10 feet high, and respectively 120, 90, and 60 feet in diameter, paved with marble and protected with balustrades. Within the enclosure is also the "palace of abstinence," where the emperor fasts 3 days preparatory to offering the annual sacrifice at the winter solstice. On the opposite side of the avenue is the altar to earth, dedicated to the supposed inventor of agriculture; it stands in an enclosure about 2 m. in circumference, and in reality consists of 4 separate altars: to the spirits of the heavens, those of the earth, the planet Jupiter, and Shin-nung, the inventor of agriculture. The worship at this altar is performed at the vernal equinox, at which time the ceremony of ploughing a part of the enclosure is performed by the emperor, assisted by members of the board of rites. A little W. of this enclosure is the pool dedicated to the spirits of the waters, where his majesty performs special supplications whenever the country suffers from drought or deluge. The southern city is not subject to the same strict military rule as the northern, and is in consequence resorted to by many persons in quest of relaxation and dissipation. During the night the great thoroughfares are usually quiet, and are dimly lighted by lanterns which hang from the doors of the houses. The air is polluted by the stench arising from private vessels and public reservoirs for urine and all kinds of offal, which is carefully collected and carried out of the gates in the same boxed carts in which the vegetables are brought to market. Carriages (or rather covered carts without springs drawn by mules), saddle horses, and donkeys are used for locomotion, and can be hired at numerous stands throughout the city; but sedans are not permitted to be used so near the emperor except by privileged persons. The Mantchoo women ride astride, and their number in the streets, both riding and walking, imparts a peculiarity to the crowd which is not seen in cities further S. The various tribes of central Asia have representatives among the throng, and their different costumes add to the liveliness of the scene.—The climate of Peking is excessively cold in winter. The thermometer ranges from 10° to 25° in winter, and in summer it sometimes rises to 105°, but is generally between 75° and 90°. Water is frozen from December to March, and violent storms and whirlwinds occur in spring. But upon the whole the climate is healthy, and epidemics are rare.—The manufactures of Peking are trifling, and the trade of the place is confined to supplying the wants of the inhabitants. The principal part of the provisions consumed comes from the S. provinces, or from the N.

part of Chi-li, the plain adjoining the city producing but little. The taxes of China are for the most part paid in kind, and large quantities of grain are stored in the principal granaries of Peking at one season of the year; but the supply becomes exhausted before the next harvest is reaped, and when this happens many of the people die of famine. Coal is brought from the S. and S. W. upon the backs of camels and mules; and the houses are heated by stoves, the fuel being a compound of coal dust and earth. All the necessaries of life are exceedingly dear, and many of the inhabitants are miserably poor.—The government differs from that of other cities in the empire; it is separated from the affairs of the department, and administered by officers residing in the 4 circuits into which it is divided. A minister of one of the boards is appointed superintendent of the city, and subordinate to him is a mayor. These functionaries are quite independent of the provincial governor, carrying any affairs which they cannot determine directly to the emperor. The police is materially assisted in its duties by the gates which are placed at the heads of the streets and closed at night, and watchmen patrol the city, marking the time by striking two pieces of bamboo together. There is frequently much trouble in keeping the populace quiet, for in times of unusual scarcity they rise in mobs and pillage the public granaries. There is a government journal called the "Peking Gazette" published daily in the form of a pamphlet, which contains from 60 to 70 pages. Nothing is printed in it without first being examined by a political or literary committee, and the official part emanates from the emperor's cabinet. It notices all public affairs, and gives a succinct account of the principal events. It contains the petitions and memorials presented to the emperor, together with his replies and his orders and instructions to the mandarins. Records of judicial events conclude the official part, which the editors cannot change or alter in any respect, without subjecting themselves to the penalty of death. Examples of this punishment, occurring from time to time, maintain among the public an almost religious respect for all that appears in the "Gazette." The journal is regarded as an expression of the emperor's will, which every one obeys, and before which every one bows.—The environs are occupied with groves, private mansions, hamlets, and cultivated fields, in or near which are trees, so that the city viewed from a distance appears as if situated in a forest. The park of Yuen-ming-yuen, or "round and splendid gardens," so celebrated in the history of the foreign embassies to Peking, lies about 8 m. N. W. from the city, and is estimated to contain 12 sq. m. The country becomes hilly in this direction, and advantage has been taken of the natural surface in the arrangement of the different parts of the ground, so that the whole presents every variety of hill and dale, woodlands and lawns, interspersed with canals, pools, rivulets, and lakes, the banks of which have been thrown up or diversified in imitation of nature. Some parts are cultivated, groves and tangled thickets occur here and there, and places are purposely left wild in order to contrast the better with the highly cultivated precincts of a palace, or to form a rural pathway to a retired summer house. The number of residences for the emperor or his ministers within this park is estimated at 30, each of which is surrounded by many houses occupied by eunuchs and servants. The summer palace and principal hall of audience, the most extensive and by far the most splendid of these residences, was plundered by the French and English forces in their advance upon Peking, in Oct. 1860. The entrance or reception hall was 110 feet long, 42 feet wide, and 20 feet high. It was paved with marble, and painted with gold, azure, and scarlet, in the most gorgeous style. The throne of the emperor was made of a dark wood beautifully carved, and the cushions were embroidered with golden dragons. The inner chambers and saloon were handsomely fitted up. The rolls of silk, satin, and crape, all of the best quality, not only furnished turbans and bedclothes for the French soldiers, but were used to wrap around fowls, old pots, and other vulgar booty. The jade stone and china were of great value, and some Sèvres china of Louis Quatorze was found; and a presentation sword with the English coat of arms, studded with gems, and evidently of antiquity, gave rise to a good deal of speculation. The English treaty of Tien-tsin was also discovered, and an immense quantity of plunder of all kinds made it difficult to decide what to take away. The emperor had retired the day before, and all the ladies had disappeared, but their little Japanese dogs were running about in a distracted state. In the treasury there was about $61,000 in gold and silver. The total value of the property carried off and destroyed amounted to several millions. Among the most curious discoveries made were a suit of magnificent armor, inlaid with gold, and the helmet surmounted with an enormous pearl; a saloon furnished in exact imitation of the style of Louis XV., decorated with the portraits of the ladies of the court of that monarch, and the name of each lady inscribed at the bottom of the frame; and among the porcelain were some immense vases which had passed more than a century at the bottom of the sea, and to which marine vegetation had clung in such a manner as to produce the most singular ornaments. Some valuable books and papers were secured for the British museum, and the coat of armor was reserved for the emperor of the French. In revenge for the cruelty with which some French and English prisoners had been massacred, this palace was burned to the ground.—Though Peking is regarded by the Chinese as one of their most ancient cities, it was not made the capital of the country until the conquest by the Mongols, when Kublai Khan, about 1262, established his court first at this spot, then called Shuntien Foo. He afterward removed it to Hang-chow. The native emperors who succeeded the Mongols held their court at Nanking, until the 3d prince of the Ming dynasty transferred the seat of government to Peking in 1411, where it has ever since remained. Under the Mongols the city was called Khan-palik, or city of the khan, and on the Chinese maps it is usually called King-sze, or capital of the court. It was at first surrounded by a single wall pierced by 9 gates, whence it is sometimes called the city of nine gates; but since then the S. suburbs have been enclosed. The N. portion was taken possession of by the Mantchoos in 1644 for barracks and residences. The government purchased the buildings from the Chinese and gave them to their officers; but necessity soon obliged these men, less frugal and thrifty than the natives, to sell them and content themselves with humbler abodes; consequently a great part of the Tartar city is now tenanted by Chinese. In the latter half of the 17th century the city was destroyed by an earthquake, and 400,000 persons are said to have perished. The Portuguese sent an embassy to Peking in 1517, but the emperor refused to receive it and the ambassadors were sent to Canton. They were imprisoned there till 1523, when they were put to death. A second embassy was sent from Goa in 1552, but proceeded no further than Malacca; and a third despatched from the same place in 1667 had not a satisfactory result. In 1723 another envoy was sent, who arrived at Peking in May, 1727, and had his audience of leave in July, receiving some gifts in exchange for the 30 chests of presents which he brought from the king of Portugal. No more advantage resulted from this than from any of the previous embassies. Another, and the last that the Portuguese sent, reached Peking in 1750, and ended much the same as the others. A Spanish envoy who came out in 1580 was imprisoned, and only released through the intervention of the governor of Macao. A Dutch embassy in 1656 reached Peking, but was not successful; and a second in 1794 was treated with contempt. The Russians have sent several embassies to Peking, and from their frontier being in contact with China have compelled the Chinese to treat them as equals. Their first recorded visit was in 1619, but it is doubtful whether it can be properly styled an embassy. In 1689 the boundary line of the two empires was fixed by treaty, and the following year the ratification was exchanged at Peking. The next mission was sent by Peter the Great in 1719, and the evident importance of keeping on good terms with the Russians led the Chinese to treat their envoys with unusual respect, and attend to the business which they came to settle. In 1727 another embassy succeeded in placing the intercourse between the two nations on a still better basis; and a mission was established at Peking, consisting of 6 ecclesiastical and 4 lay members, to study the Chinese and Mantchoo languages, so that interpreters could be prepared and communications carried on more satisfactorily; the members of this college are changed decennially. The intercourse of the English with China, though it commenced later than that of most of the other maritime nations of Europe, has been far more important in its results. Their commercial transactions with the Chinese became so complicated toward the close of the last century, that it was determined to send an embassy to the court of China to place their affairs on a better footing. In 1792 Lord Macartney was despatched with a large suite, and presents for the emperor, which it is supposed were looked upon as valuable tribute. Though the embassy failed in its most important points, it nevertheless produced some good effects, and for many years the trade went on without interruption. Further difficulties arising between the English and Chinese, a second embassy was sent under Lord Amherst, arriving at Peking in Aug. 1816. This mission was summarily dismissed without an audience, because the ambassador would not perform *kotow*, or appear before his majesty the day he arrived. A letter was sent from the emperor to the prince regent, in which among other things it was said: "I have sent thine ambassador back to his own country without punishing him for the high crime that he has committed." The intercourse of foreigners was for many years after this in a very unsatisfactory condition. On June 13, 1858, Count Putiatine, the Russian ambassador, signed a treaty in which the chief points conceded by the Chinese were the right of correspondence upon an equal footing between the Russian minister of foreign affairs and the first minister of state at Peking; permission to send diplomatic agents to that city upon special occasions; liberty of circulation throughout the empire for missionaries under a system of passports; and the right to trade at ports then open, and in addition at Swatow, at a port in Formosa, and another in Hainan. On the 18th of the same month the American treaty was signed by Mr. Reed, in which the same privileges were accorded to the government of the United States, and a clause added conferring all privileges that might in future be granted to "the most favored nation." A few days afterward the English and French treaties were signed, respectively by Lord Elgin and Baron Gros at Tien-tsin. In due course the ratified copies of the American and Russian treaties were exchanged at Peking; but a dispute arising between the ambassadors of other powers and the Chinese with regard to the route by which they should proceed to the capital, they were forced to retire. Early in Oct. 1860, an English and French force upward of 25,000 strong, after destroying the summer palace and devastating several cities, quietly encamped within the earthwork about a mile outside the N. wall of Peking. The emperor had escaped to an ancient palace beyond the great wall, and had left his brother, Prince Kung, who was authorized to treat as plenipotentiary with the invaders. The prince showed great reluctance in complying with some of the demands made by Lord Elgin and Baron Gros, and only yielded when assured that Peking would be utterly destroyed in case of his refusal. One of the city gates was placed in the hands of the French and another in those of the English; and every thing was done that appeared likely to humble the minister and mortify the pride of the Chinese emperor. On Oct. 24, the day appointed by Lord Elgin for exchanging the ratifications of the treaty of Tien-tsin, and signing the convention of Peking, the streets leading to the prohibited city were occupied and the audience hall within its limits where the ceremony took place surrounded by British troops. Lord Elgin passed through the streets with a numerous escort, and entered the audience hall with his suite, bowing coldly to Prince Kung, who approached with the usual salutation of respectful greeting, and appropriating to himself the most honorable seat, placing Sir Hope Grant, the commander-in-chief, in a chair on his left. On the following day the same ceremonies were performed between the French and Chinese plenipotentiaries. The substance of the treaty was as follows: 1, the emperor of China expressed regret at the misunderstanding occasioned by the affair at the Taku forts; 2, the right of the queen of Great Britain to keep a resident minister at Peking was acknowledged; 3, £3,100,000 was to be paid by the Chinese government as indemnity; 4, Tien-tsin was opened to trade; 5, the interdict upon the emigration of Chinese to the British colonies was removed; 6, a portion of the mainland opposite Hong Kong, called Cowloon, was ceded to the British; 7, the immediate operation of the treaty and convention was provided for. The French also received a large indemnity, and Tien-tsin was to be occupied by the allies till their claims were satisfied. Though this was the first formal embassy sent by the French to Peking, they have by their missionaries made the rest of the world better acquainted with China, and given the Chinese more knowledge of western countries, than all other Christian nations together.

PELAGIUS, the founder of a religious system in the 5th century. Little is known of his life. He was a British monk named Morgan (signifying sea-born), of which Pelagius is a translation, and by the incursions of barbarians was driven from his native land. He went first to Rome (409), where he made the acquaintance of Cœlestius, and the two afterward (411) went to Carthage. Pelagius soon left Africa for Palestine, but Cœlestius, who endeavored to be received among the presbyters of Carthage, was accused of heresy before a synod held at that place in 412 and condemned. The doctrines on the ground of which he was declared guilty of heresy, are the following: 1, Adam was created mortal, so that he would have died whether he had sinned or not; 2, Adam's sin injured only himself, and not the human race; 3, new-born infants are in the same condition in which Adam was before the fall; 4, the whole human race neither dies in consequence of Adam's death or trangression, nor rises from the dead in consequence of Christ's resurrection; 5, infants obtain eternal life, though they be not baptized; 6, the law is as good a means of salvation as the gospel; 7, there were some men, even before the appearance of Christ, who did not commit sin. These 7 propositions (others count only 6, leaving out the 5th, or joining it to one of the other propositions) were and still are regarded as the cardinal points of the Pelagian system, although it is difficult to decide how far Pelagius accorded with all of them, since he expressed himself very cautiously. In consequence of the condemnation of Cœlestius, Pelagius himself was soon attacked in Palestine, where Jerome became one of his most zealous opponents. Jerome, conjointly with Orosius, a disciple of Augustine, accused Pelagius at a synod held at Jerusalem in 415, under John, bishop of that city. John, however, did not pronounce his condemnation, but referred the whole matter to the see of Rome, then occupied by Innocent I. At another synod of 15 bishops, held in the same year at Diospolis, under Eulogius of Cæsarea, Pelagius was acquitted. The churches of Africa, on the other hand, reiterated their rejection of the system in a synod of 69 bishops held at Carthage, and in a synod of 61 Numidian bishops at Mileum, both held in 416. Both synods urged Innocent to pronounce on this subject, as did also, in a private letter, Augustine, who now entered the arena as the most powerful opponent of Pelagianism. The reply of Innocent was to the satisfaction of the African bishops, and Pelagius deemed it necessary to address to him an explanatory apology of his system, which, however, did not reach Rome until after the death of Innocent. His successor, Zosimus, was induced by the confession of faith that Cœlestius, who was now in Rome, had drawn up, and also by the letters and protestations of Pelagius, to declare the two accused sound in faith, and unjustly persecuted by their adversaries. The African bishops, 214 in number, met again in a synod at Carthage, and stood by their former decision; and Augustine appealed to the emperor Honorius (418), who issued a rescript to the prefect, ordering the immediate suppression of the new heresy. Another council at Carthage, which was attended by delegates from all the provinces of Africa and even from Spain, specified and solemnly condemned as heretical 9 doctrines of Pelagius. Similar declarations were issued by the bishops Theodotus of Antioch and Praylius of Jerusalem; and Zosimus now also lost confidence in the new teachers, and published his *Epistola Tractoria*, in which the Pelagian doctrine is condemned. All the bishops of the western churches were called upon to subscribe to this epistle; many yielded, but Julian, bishop of Eclanum in Apulia, the most gifted of all Pelagian theologians, undertook the defence of the system, though without success. He had to sacrifice his office, and to repair with Pelagius and Cœlestius to Asia, where some more fruitless efforts were made to gain influential bishops, as Theodore of Mopsuestia and Nestorius of Constantinople, over to their cause. Little is known of the farther history of Pelagius, his two friends, and their doctrines, except that the last were again condemned as heretical by the œcumenical council of Ephesus in 431. The followers of Pelagius never formed a sect properly so called; but Pelagianism, as a theological system, though condemned, retained its adherents. The best works on the history of Pelagianism are: Wiggers, *Versuch einer pragmatischen Darstellung des Augustinianismus und Pelagianismus* (2 vols., Berlin, 1821–'3; English translation by Prof. Emerson, New York, 1840); Jacobi, *Die Lehre des Pelagius* (Leipsic, 1842).

PELARGONIUM. See GERANIUM.

PELASGIANS (Gr. Πελασγοί), an ancient people, who in pre-historic times occupied the Grecian peninsula, the islands and coasts of the *Ægean*, and portions of Asia Minor and Italy. Our knowledge about them is very vague and contradictory. The term is sometimes used in a broad sense to include the great ethnological family who were the earliest inhabitants of Greece and Italy, and sometimes in a narrower sense to mean only a single tribe or nation of that family. The most ancient writers give the name a wide rather than a narrow meaning. Homer, who was the first to mention them, connects them at once with Crete, Dodona, and Thessaly. Æschylus makes Pelasgus, the king from whom the race derived its name, a ruler over the whole of Greece; while Herodotus says that Greece was called Pelasgia, and includes under the common name of Pelasgians the Athenians, the Arcadians, the Ionians of Asia Minor, the Lemnians, the Samothracians, and the Crestonians. On the other hand, Thucydides, whose authority is of the highest weight, states that the Pelasgians were only the most numerous of the many kindred races which inhabited Greece. They came from the East at a very early period, passing over from Asia Minor, where they had built the two cities which bore the name of Magnesia, to the islands and the mainland of Greece, and establishing themselves principally in Thessaly, Epirus, and Peloponnesus. The Arcadians, Ionians, and Argives seem to have been Pelasgian races. Attica was Pelasgic at a very remote period, and the earliest population of Macedonia may have been of the same stock. In Italy the southern nations, such as the Peucetians, Daunians, and Japygians were of Pelasgic race; and there is reason to suspect that the same element entered largely into the composition of the Latin people. At one time the population of Etruria was also Pelasgian to a very great extent. At the beginning of authentic history the Pelasgians of Asia were a declining race, holding only a few scattered posts, "the last strongholds," says Rawlinson, "of a people forced everywhere to yield to conquerors. The natural explanation of the historical phenomena is that the Pelasgi were the original population of western Asia, and that their emigrations across the sea into Europe were occasioned by the pressure upon them of immigrants from the east, Lydians, Phrygians, and Carians, who forced them westward, and so caused their occupation of Greece and Italy." The Pelasgians of Europe were celebrated for their wanderings, to which they were apparently compelled by the encroachments of stronger races who drove them from country to country. Their leading characteristics seem to have been peaceful habits, agricultural pursuits, a love of navigation, and a natural taste for art. They were skilled in fortification, and in every land which they once inhabited their presence can still be traced by numerous works of defence, built of immense polygonal blocks of stone fitted together without mortar or cement, and of such substantial strength that they have outlasted the structures of succeeding ages and races. These works are commonly known as Cyclopean, a name given to them for their grandeur and antiquity. The ultimate fate of the Pelasgians is wrapped in mystery. They disappeared a few centuries before Christ, probably absorbed by other races more or less akin to them. In Greece proper they mingled with the Hellenes, and in Asia Minor with the Carians, the Lydians, and the Phrygians; while in Italy they were either reduced to the condition of serfs or united with their conquerors to form a new people, the Latins. "Their whole character," says Rawlinson, "was plastic and yielding, not firm nor formative; and their fate was to furnish a substratum upon which stronger nationalities established and developed themselves."

PELEW ISLANDS, a chain of islands in the N. Pacific ocean, forming part and situated at the W. extremity of the Caroline archipelago, between lat. 7° and 8° 30' N., and long. 134° and 136° E. The group consists of about 20 principal islands, nearly encircled by a coral reef, and covers an extent of about 120 by 20 m. Babelthouap, the largest of the islands, is about 28 m. long and 14 broad, and contains a mountain so high that the whole group may be seen from its summit. When seen from the sea the islands appear rugged and mountainous; but the soil is rich and fertile, and the whole are watered by several brooks and ponds. They are well wooded, and produce breadfruit, cocoanuts, bananas, sugar cane, yams, lemons, and oranges, beside numerous other tropical fruits and vegetables. Horned cattle, pigs, goats, and fowl are numerous; and turtles, fish, and shell fish abound on the coasts. The inhabitants are of the Malay race. They pay great attention to the cultivation of their ground, and show considerable ingenuity in making their canoes, some of which can carry 80 men. The men go entirely naked, and the women almost so.—The Pelew islands are said to have been discovered by the Spaniards in 1545, and they were afterward seen several times by ships bound to China by the E. passage; but they were first brought to the notice of the civilized world by the loss of the British ship Antelope, Capt. Wilson, in 1783. The natives treated the crew of the wrecked ship with the greatest kindness. Capt. Wilson took the son of the chief to England, where he was placed at school and displayed considerable aptitude for civilized customs and an excellent disposition; but he died of small pox, at the age of 20, the following year. Several other narratives of voyagers give an equally favorable account of the islanders; but it would appear that a more extended acquaintance with the white man has made them treacherous. The Siren, whaler, when passing the S. island in 1823, was boarded by 100 men who appeared to be friendly, but when opportunity offered attacked the crew, and were only repulsed after a desperate fight, in which most of the ship's company, 37 in number, were wounded and 2 officers killed. Since then several vessels have had very narrow escapes from being cut off while visiting the islands.

PELICAN, a genus of large, web-footed birds (*pelecanus*, Linn.). The bill is very long, nearly straight, and much depressed; the upper mandible has an elevated ridge, becoming flat toward the end, the tip being strong, hooked, and acute; the lower mandible is wider at the base than the upper, and its branches are united only at the tip; the nostrils are scarcely perceptible, in the lateral groove at the base; the wings are moderate, the 2d quill the longest, and the secondaries nearly as long as the primaries; the tail is broad, short, and rounded; the tarsi short and stout, covered with reticulated scales; all four of the toes on the same plane, the hind one turned more or less inward, and all connected by broad webs, the middle toe the longest. The head is moderate and crested, the neck long and slender, and the feet toward the middle of the body; under the lower jaw, and extending to the throat, is a loose, naked membranous pouch capable of great distention, which is used as a scoop-net for fish; around the eyes and base of the bill are bare spaces. The skeleton is remarkable for the great extent of its air cavities, the bones weighing less than 2 lbs.; from these the air penetrates into the areolar tissue under the skin, making the body for its bulk exceedingly light; the œsophagus is very capacious and the stomach small. The species are not numerous, but are found in most parts of the world, and most abundantly in tropical regions, frequenting both the sea coast and interior lakes and rivers; they are very voracious, feeding entirely on fishes, and the pouch is capacious enough to hold fish sufficient for the dinner of half a dozen men; they are good swimmers, divers, and fliers, and can perch easily on trees. In the morning and evening they leave their roosting places in flocks of about a dozen, and fly to their fishing grounds; they fish until satisfied, swallowing their prey on the spot, and retiring with a full crop to some solitary place to digest it; they often doze on the water during the progress of digestion. They fly sometimes elevated, and at others skim near the surface, and, balancing themselves when they see a fish, fall headlong upon it with the apparent risk of breaking their necks.—The white pelican (*P. onocrotalus*, Linn.), the *onocrotalus* of Pliny but not of the Greeks, is between 5 and 6 feet long, and 12 to 13 in expanse of wings; the general color is white, with rosy tinges, and the primaries are black; the upper mandible is bluish with red and yellow tints, and the hook on the end is bright red; the pouch is yellow. It is found in S. E. Europe, Asia, and Africa, sometimes coming as far W. as Germany, but not to Great Britain. The nest is generally made in a rude manner on inaccessible rocks, near fresh or salt water, and the eggs are 2 to 4; it builds sometimes on trees remote from water; the young are fed by the regurgitated food of the parents; this operation is rendered easier by pressing the pouch and lower mandible against the breast, and the contrast of the red hook of the bill against the white of the breast probably gave rise to the poetic idea of the ancients that the female pelican nourished her young with her blood. It is a very long-lived bird; in captivity it will eat rats and small mammals as well as fish; its flesh was forbidden to the Jews, and few would care to eat it, as it is very rank, fishy, and oily; it is said to have been tamed and employed in fishing, like the cormorant among the Chinese. Its pouch has been used to make caps and bonnets and tobacco bags; the Siamese make of it strings for musical instruments, and the Nile and other boatmen use it with the lower jaw attached for baling water from their canoes; it will hold in the living bird 10 to 12 quarts of water, and hence the pelican is called "river camel" by the Egyptians. A variety or species (*P. crispus*, Bruch.) in S. E. Europe is somewhat larger, of a more grayish white, with curled feathers on the back and sides of the head; these collect in flocks, and extending their line in the form of a crescent, by flapping their wings and plunging into the water, drive a shoal of fish into a small and shallow space, and there speedily obtain a full supply.—The American white or rough-billed pelican (*P. trachyrhynchus*, Lath.; genus *cyrtopelecanus*, Reich.) is about 6 feet long, with an alar extent of between 8 and 9 feet, and a weight of 17 or 18 lbs. It much resembles the *P. onocrotalus*, being of a general white color, tinged with roseous in the breeding season; the primaries are black, and the iris white; the head and neck are covered with slender, small, and downy feathers, elongated into a crest on the nape and running down the back of the neck; on the body generally the feathers are narrow and long; the crest is yellow, the eyes very bright, and in spring the legs, feet, bill, and pouch are orange red, fading to yellowish in the autumn. The bill is 14 inches long, and the sac beside this length extends 8 inches on the throat, being 7 inches deep at the widest part; the wings are long, narrow, and rounded, and the primaries much curved; the tail consists of 24 feathers; the horny and fibrous ridge on the upper mandible of the males increases with age, and is used as a means of defence in their battles during the love season; the females are rather smaller than the males. Abundant during the winter in Florida, it is found in summer in the interior of the fur countries as far as lat. 61° N.; it does not occur on the coast of the middle and northern states, as the course of migration is along the great inland rivers. They do not dive for their prey either from the wing or the surface of the water, but thrust the head under as far as the neck will allow, feeding mostly in shallow places, as they swim along against wind and current with the wings partially extended and the upper mandible only of the bill appearing above the surface; they are sometimes seen in company with the brown species, next described; occasionally they drive fish in shallows, where they can easily scoop them up with the pouch. As they stand upon the sand bars, they have a sedate and grave look, and a very ludicrous habit of gaping or opening their long mandibles; they are rather stupid, and not very shy; inactive during most of the day, they fish in early morning and evening; the gait is very awkward; they are said to be very tenacious of life. They destroy a great number of small fish; several hundred minnows have been taken from the stomach and œsophagus of a single individual; when approached after a full meal they disgorge their food like the vultures; the flesh is rank and fishy, and unfit for food. The sac is expanded by the opening of the bill, and *vice versa*. They breed in the fur countries, but not generally in the south like the next species; they are found in the Rocky mountains and in California.—The brown pelican (*P. fuscus*, Linn.; genus *onocrotalus*, Wagler) differs from the last species in habits, size, and colors; it is a smaller bird, being only about 56 inches long, with an extent of wings of 7 feet and a weight of 7 or 8 lbs. The bill is 13½ inches long, grayish white, tinged with dusky and with spots of carmine; there is no ridge on the upper mandible; the orbital space is blue, the crest light chestnut red, and the tail has only 22 feathers. The head and sides of the neck are white; the hair-like feathers of the forehead yellow; the neck behind and in front below dark chestnut brown; back, wings, and tail grayish ash, margined with dusky, the last with the shafts white at the base and black at the end; primaries brownish black; below dark brownish ash, with narrow longitudinal white lines on the sides; iris white; legs and feet black. The female is like the male, but the feathers of the head are more rigid; the young are dusky brown. It is found from North Carolina to Texas, and on the coast of California; it is a constant resident in Florida, and is now rare N. of St. Augustine; it goes south far beyond the limits of the United States; it is not seen on fresh water beyond the reach of the tide, like the white pelican. The flight, though apparently heavy, is well sustained, performed by alternate easy flappings and sailings, and in long undulating lines; in calm weather they perform intricate aërial evolutions at a great height; during flight the head is drawn between the shoulders and the feet extended. They are always awake during the coming in of the tide, which is the favorable time for fishing; they are never seen far from shore when a storm is threatening, and their appearance at sea is regarded by sailors as a sure sign of pleasant weather. They procure their food on the wing, plunging from a height of 15 to 25 feet, with the lower mandible wide open and the pouch extended, scooping up the fish and swallowing them at once; their plunge is very singular, and seems to the spectator calculated to break the neck; giving no indication of being about to plunge, as diving birds usually do, they fall suddenly as if from apoplexy, striking the water with great force and splashing it about so that it is impossible to determine whether the whole body is immersed or not. They do not carry fish or water to their young in the pouch, as has been generally believed, and, according to Audubon, this part is always contracted during flight. It is not uncommon to see these birds with a hole through the pouch caused by the spine of a fish, and their throats are occasionally reddened by the blood which has flowed from such a wound. They are fond of following porpoises, picking up their share of the terrified fish on which these cetaceans feed; and in their turn they involuntarily provide for the black-headed gull (*larus atricilla*, Linn.), which watches their plunges, and as they emerge alights on their head or bill, seizing any small fry which may protrude beyond the bill or pouch; the pelicans do not seem to notice the thefts or clamor of the gulls, and make no attempts to dislodge or drive them away; this is certainly a very curious instance of animal instinct and fraternization. They are awkward walkers, but buoyant swimmers; when wounded they will bite severely; they feed on fish generally 2 or 3 inches long, rarely taking one as long as the bill; they are powerful birds, but very sensitive to cold; the flesh is tough and unfit for food, and the eggs are not much better; the senses of sight and hearing are very acute;

they are among the most silent of birds. They always keep in flocks of from 20 to 60, and begin to pair by the middle of April; the nest is made of sticks, lined with leaves and grasses, and placed high on a mangrove tree; many nests are built in the same tree, and the trees are often near together; they breed in company with the egrets, herons, and spoonbills, and on islands frequented also by white ibises and frigate pelicans; if not disturbed they use the same breeding places year after year. The eggs, 3 in number, 3¼ by 2¼ inches, are thick-shelled and rough, white, more or less tinged with blood. The young are at first fed by regurgitation of the food of the parents, and so abundantly that the refuse fills the air with the most disgusting odor; they grow fast, and are very fat; they are highly prized as food by the Indians and negroes, and form a *bonne bouche* for many a vulture.

PELIDES. See ACHILLES.

PELIGNI, an ancient people of central Italy, of Sabine origin, who dwelt between the Marrucini, the Marsi, Samnium, and the Frentani. They were renowned as warlike, like the Marsi reputed as magicians, and long warred against the Romans, but together with their neighbors concluded a peace with the republic about the end of the 4th century B. C. They played a principal part in the social war, one of their chief towns, Corfinium, near the Aternus, being selected by the allies as the future capital of Italy, and therefore surnamed Italica. They were finally subdued in 89 B. C., by C. Pompeius Strabo, the father of Pompey the Great.

PELION (now *Zagora*), in ancient geography, a mountain range of Thessaly, extending along the coast of Magnesia, and forming the promontories of Sepias and Æantium. On the N. it is connected by a low ridge with Mt. Ossa. On its summit there was a temple of Jupiter Actæus, and near this was fabled to be the cave of the centaur Chiron. Its magnificent forests, for which it is still distinguished, furnished the timber for the ship Argo, and the shaft of the celebrated spear of Achilles. In their war with the gods, the giants are said to have attempted to scale heaven by piling Pelion and Ossa on Olympus, or Ossa and Olympus on Pelion. The name Plessidhi is now applied to the N. W. summit of Pelion.

PÉLISSIER, AMABLE JEAN JACQUES, duke of Malakoff, a marshal of France, born at Maromme, near Rouen, Nov. 6, 1794. He studied at the military schools of La Flèche and St. Cyr, and became a sub-lieutenant of artillery two days before the return of Napoleon from Elba. He served in Spain in 1823, became a captain in 1828, served in Greece, and in 1830 took part in the expedition against Algeria. In 1832 he returned to France in ill health, but in 1839 he went back to Algeria as a lieutenant-colonel, and remained there more than 16 years. In July, 1843, he was made colonel, and commanded the left wing of the army in the battle of Isly. During the insurrection of the Kabyles in 1845 he entered the territory of the Ouled Riahs, an Arab tribe who took refuge in one of the spacious caverns in which their country abounds. Into these fastnesses they were accustomed to retire, and from the inability of an enemy to penetrate them, the tribes had begun to consider themselves invincible. To all summonses to surrender they refused to listen, and even prevented the approach of messengers by the discharge of firearms, although aware that death would be the consequence of their unwillingness to comply with the terms offered. After 28 hours spent in fruitless negotiations, Pélissier applied burning fagots to the mouth of the cave, and suffocated nearly 600 of the Arabs. The transaction excited great horror, as well in France as in other countries. Marshal Soult, then minister of war, condemned it formally, but Marshal Bugeaud declared that his subordinate had acted in accordance with his orders, and justified the operation as "a necessity of war." In 1846 Pélissier became brigadier-general, and in 1851 general of division. He remained in Algeria until Jan. 1855, when he was suddenly ordered to the Crimea as second in command to Gen. Canrobert; and when on May 19 Canrobert resigned he was appointed in his place, which he retained till the close of the war. Immediately after the fall of Sebastopol Pélissier was created marshal of France and duke of Malakoff, from the captured Russian fortification of that name, and was voted by the legislative body a pension of 100,000 francs. He replaced Count Persigny as minister to England in April, 1858, but was recalled in April of the following year in order to take command of the army of observation, the head-quarters of which was at Nancy. He has been made a member of the privy council, a vice-president of the senate, and in July, 1859, was appointed grand chancellor of the legion of honor. Queen Victoria has also conferred upon him the honorary grand cross of the order of the bath.

PELLERIN, JOSEPH, a French antiquary, born in Marly le Roi in 1684, died in Paris in 1782. He held a subordinate office in the navy department, and devoted the leisure hours of his long life to the collection of medals. He accumulated 32,500 specimens, which he finally sold to Louis XVI. for 300,000 francs. He previously had them engraved and published under the title of *Recueil de médailles des rois, peuples et villes* (10 vols. 4to., Paris, 1762–'78), with explanations and critical observations.

PELLEW, EDWARD. See EXMOUTH.

PELLICO, SILVIO, an Italian poet and patriot, born in Saluzzo, Piedmont, in 1789, died at the villa of Moncaglieri near Turin, Jan. 1, 1854. His father, who owned a silk manufactory at Pignerol, was a man of literary taste. About 1795 the family removed to Turin, and Silvio studied under a priest until he accompanied his sister, on her marriage, to Lyons. There he remained several years, gaining an intimate knowledge of the French language and literature, and a taste for French manners. His native land was almost forgotten, when the reading of Ugo Foscolo's poem, *I sepolcri*, which appeared in 1807, exercised a great influence over his studies and feelings; and in 1810 he returned to Italy, taking up his residence in Milan, where his father had obtained a situation under the government. There he became a teacher of French in the *collegio degli orfani militari*, and spent his leisure hours in acquiring the English and German languages and in poetical studies. Foscolo and Monti, then at Milan, welcomed him warmly; and soon afterward entering the family of Count Luigi Porro Lambertenghi as tutor, he became acquainted with many distinguished persons, among whom were Mme. de Staël, Schlegel, Byron, Hobhouse, Davy, and Brougham. His first production was the tragedy of *Laodamia*. It was followed by that of *Francesca da Rimini*, founded upon a passage in Dante's *Inferno*. This immediately excited considerable sensation, was acted in the principal theatres of Italy, and gave Pellico a high rank as a dramatic poet. His next work was a translation of Byron's "Manfred." In 1819, with some other literary men, he established a journal called *Il conciliatore*, and in this periodical his *Eufemia di Messina* and Manzoni's *Conte di Carmagnola* first appeared. Sismondi, Romagnosi, Gioja, and other prominent men of letters contributed to its columns. On account of its liberal tendencies it was early subjected to a rigid censorship by the Austrian authorities, and in 1820 it was entirely suppressed. About this time Pellico appears to have become a member of the revolutionary society of the carbonari. The insurrections which broke out both in Naples and Piedmont now gave the Austrians a pretext for severe proceedings in the case of suspected individuals, and on Oct. 13, 1820, Pellico was arrested. He was first confined in the prison of Santa Margherita at Milan, and thence was removed to a state prison on the island of San Michele near Venice, called "the Leads." Here he remained until his trial in Feb. 1822. He was condemned to death, but by an imperial rescript the sentence was commuted to 15 years of severe imprisonment (*carcere duro*). In April, 1822, he was taken to the prison of Spielberg near Brünn in Moravia, where, through the kindness of his gaoler, he was treated with comparative indulgence for about 18 months, being allowed to read the Bible, Homer in Greek, and several favorite Italian, German, and English authors. But the gaoler was removed, and from this time his treatment during the remaining years of his imprisonment was exceedingly rigorous. "Those condemned to *carcere duro*," says he, "are obliged to labor, to wear chains on their feet, to sleep on bare boards, and to eat the poorest food." In this manner Pellico dragged on a miserable life, until, when nearly at the point of death, he was freed by an imperial order on Aug. 1, 1830. He was taken to the Piedmontese frontier, and spent the rest of his life at Turin, acting as secretary to the marquis of Barolo. In 1832 he published an account of his 10 years' suffering, in a work entitled *Le mie prigioni* ("My Prisons"). This volume, which at once became widely celebrated on account of the intense interest of the story, and the simple pathos and unaffected piety pervading its pages, has been translated into English, 2 times into Spanish, 5 times into German, and 15 times into French. After his release he spent his life chiefly in literary pursuits. His "Works" were published in Padua in 2 vols. (1831); and at Turin, under the title of "Three New Tragedies," appeared in 1832 a volume containing his *Gismonda da Mendrisio*, *Leoniero da Dertona*, and *Erodiade*. The following year he published the tragedy of *Tommaso Moro*. In 1837 a collection of his "Inedited Works" appeared in 2 vols. One of his last productions was a religious treatise in prose, entitled "The Duties of Man." His life was written by Chiala in 1852.

PELOPIDAS, a Theban general and statesman, killed at the battle of Cynoscephalæ, in Thessaly, in 364 B. C. He was the son of Hippocles, a man of noble descent, and inherited great possessions, of which he made a liberal use. In a battle in which he was in imminent danger of losing his life, he was saved by Epaminondas at great risk; and from this time a friendship began between these two patriots, which lasted until the death of Pelopidas. His wealth and his devotion to public affairs made Pelopidas a prominent member of the popular party, so that, upon the seizure of the Cadmea by the Spartan general Phœbidas in 382 B. C., he with 300 others went into voluntary exile at Athens. There he remained 3 years, seeking an opportunity of overthrowing the Spartan rule in Thebes; and there finally was projected that enterprise which, according to Plutarch, was called by the Greeks "sister to that of Thrasybulus," and which restored democracy to Thebes. With 6 others he entered that city at nightfall, put to death the philo-Laconian polemarchs, slew Leontiades, the leader of the Spartan party, with his own hand, and gained possession of the citadel by the garrison's capitulating and consenting to withdraw. From that time until his death he was every year elected one of the Bœotarchs, and during the following year he bore a conspicuous part in the war against the Lacedæmonians. In 375, while returning from an attempt to surprise Orchomenus, he fell in at Tegyra with a Spartan force superior to his in numbers. When the messenger communicated the news, saying: "We have fallen into the midst of enemies," Pelopidas answered: "Why so, more than they into the midst of us?" and in the battle which followed was completely victorious. At Leuctra in 371 he coöperated with Epaminondas in inspiring resolution into his timid countrymen, and in the proposal of hazarding an immediate battle. In the engagement he commanded the sacred band, which led the charge against the enemy's right wing, and by defeating it decided the fate of the day. Afterward he seconded Epaminondas in persuading their colleagues in the army to march into the Spartan territory, although by so doing they would exceed their terms of office, an offence which according to law was punishable with death; yet on their return they were triumphantly acquitted. In 368 Pelopidas marched at the head of a Theban force to succor the inhabitants of Thessaly, oppressed by Alexander of Pheræ; he occupied Larissa, and compelled the tyrant to acknowledge his authority. Advancing into Macedonia, he composed the differences between Alexander II. and Ptolemy of Alorus, and took as hostages for their future good conduct 30 boys, among whom was Philip of Macedon. In 367 he was sent as an envoy to the Persian court at Susa, where, though he refused to make the customary prostration to the monarch, he obtained every thing for which he came, viz.: a rescript of the great king that Messene and Amphipolis should be autonomous cities; that Athens should order home all the ships in active service; and that Thebes should be deemed the head city of Greece, and any cities refusing to acknowledge her leadership should be threatened with compulsion by a Persian force. But this rescript was treated with contempt by most of the Grecian cities, and in performing a mission in Thessaly, in order to obtain its recognition, Pelopidas was treacherously seized as a prisoner by Alexander of Pheræ. A Theban force, in which Epaminondas served as a private soldier, was sent to rescue him, but failed in accomplishing its object in consequence of the alliance of the Athenians with the tyrant. A second expedition under the leadership of Epaminondas succeeded in releasing Pelopidas, who during his confinement is said to have treated Alexander with marked defiance. But the power of the tyrant of Pheræ was still predominant in Thessaly, and in consequence of repeated missions on the part of the inhabitants complaining of his cruelty, Pelopidas was despatched in 364 into that country at the head of an army. Although the portents were unfavorable, and his troops were terrified by an eclipse of the sun, he pressed on. Arriving at Pharsalus, he encountered Alexander at the head of a larger force than his own, and a contest immediately ensued as to which should gain possession of the hills called Cynoscephalæ. After a severe struggle, the tyrant was defeated; but Pelopidas, seeing Alexander himself, and burning with a desire to revenge his imprisonment, rushed to the spot where he was standing, attended by a few soldiers only, and was slain. His death caused great lamentation both among the Thebans and Thessalians, the latter asking and obtaining permission to take the chief part in his funeral. Pelopidas, though inferior to Epaminondas in military skill and mental power, was nevertheless one of the most prominent men Thebes ever produced; a devoted patriot, a disinterested friend, and so absorbed in his devotion to the public good, that he neglected all care of his private fortune, and to the remonstrances of his friends would reply that money was certainly useful to such as were lame and blind. His life was written by Plutarch, but the order of events given by him differs somewhat from that given above.

PELOPONNESIAN WAR. See GREECE.

PELOPONNESUS (Gr., "the island of Pelops," so called by the Greeks because King Pelops was supposed to have settled a colony there), a peninsula at the S. end of Greece, forming one of the great geographical divisions of that country, and now called the Morea; area, 7,779 sq. m.; pop. in 1856, 562,841. It lies between lat. 36° 23′ and 38° 20′ N., and long. 21° 5′ and 23° 30′ E., and is about 135 m. in length and the same in extreme breadth. The Greeks compared its shape to that of the leaf of a vine or a plane tree. The coast is much indented, on the S. by the gulfs of Laconia or Kolokythia and of Messenia or Coron, and on the E. by the gulf of Argolis or Nauplia. It is connected with central Greece by the isthmus of Corinth, which is 5 m. wide at the narrowest part, and separates the Corinthian from the Saronic gulf. The surface of the peninsula is generally mountainous. In the centre a long and lofty ridge bent into a circular form encloses an elevated basin, the famous vale of Arcadia, the largest of the ancient states. Five other ranges, running from the different sides of the central one to the 5 most prominent points on the coast of the peninsula, enclose plains or valleys which formerly were the seats of 5 states: Achaia in the N., Argolis in the E., Laconia and Messenia in the S., and Elis in the W. The mean height of the mountains is about 1,200 feet, but on the W. side they attain a height of from 3,000 to 4,500 feet. Mt. Cyllene, on the N. side of Arcadia, rises to the height of 7,788 feet; and Mt. Taygetus, the ridge which stretches southward from Arcadia to Cape Matapan (anc. *Tænarum*), is at the highest point about 8,000 feet above the sea. The principal rivers are the Alpheus, now called the Rouphia, which rises in Arcadia and flows W. through Elis into the Ionian sea; and the Eurotas, now the Vasilipotamo, which rises in the N. of Laconia and flows southward into the Laconian gulf. The climate is mild and the soil fruitful. The chief productions are corn, wine, oil, and fruits, honey, figs, silk, cotton, and the small raisins called currants, which are the principal article of export. At present the peninsula is divided into 5 nomes or provinces, viz.: Argolis and Corinth, the capital of which is Nauplia; Achaia and Elis, capital Patras; Arcadia, capital Tripolitza; Messenia, capital Kalamata; and Laconia, capital Sparta. Its ancient population has been computed at 2,000,000, which is probably an exaggeration, though it was certainly much more populous and flourishing than at present. It contains many ruins of famous ancient cities, among which those of Sparta, Mycenæ, and Mantinea are the most interesting.—About 80 years after the fall of Troy, Peloponnesus was conquered by the Dorians, led by the descendants of Hercules, who claimed possession of the country by ancestral right. This event is known in history as the return of the Heraclidæ. The Dorians established several states, one of which, Sparta or Laconia, became under the institutions of Lycurgus the most powerful in Greece. A combination of the Peloponnesian states against Athens in the latter part of the 5th century B. C. gave rise to the great contest known as the Peloponnesian war. In the decline of Greece in the 3d century B. C. a temporary importance was given to Peloponnesus by the Achæan league, to which a political organization was given by Aratus in 251, and which played a dominant part in the affairs of Greece till the conquest of the country by the Romans in 146. On the division of the Roman empire Peloponnesus became subject to the emperor of Constantinople; and on the decline of the eastern empire it was taken possession of by the Venetians, from whom the Turks conquered it in the middle of the 15th century. The Venetians regained it in 1699, but restored it to Turkey in 1715. During the Greek revolution of 1821–'8 it was the theatre of many interesting events, and the result of that struggle left it a portion of the present kingdom of Greece. (See Greece.)

PELOPS, in Grecian mythology, the son of Tantalus and grandson of Jupiter. His father, having invited the gods to a banquet, killed Pelops, and served up his remains at table. Ceres in a fit of abstraction ate a piece of the shoulder; but the rest of the immortals, perceiving what the dish was, ordered Mercury to restore the youth to life by putting the flesh in a caldron. Pelops was accordingly taken out alive, and in place of the part which Ceres had eaten received a shoulder of ivory, whence all his descendants, the Pelopidæ, were supposed to have one shoulder remarkably white. Afterward he applied to Œnomaus, king of Pisa, for the hand of his daughter Hippodamia; but the king, having been told by an oracle that his son-in-law would kill him, refused unless Pelops should conquer him in a chariot race, declaring however that he would take his life if he failed. Pelops bribed the king's charioteer Myrtilus to remove the linchpins of the royal chariot, and in the race Œnomaus was thrown out and killed. The victor then took Hippodamia to wife, assumed the government of Pisa, and soon made himself master of Olympia, where he restored the Olympic games with great splendor. He had promised Myrtilus half the kingdom, but after he had gained his object threw him into the sea. By Hippodamia he had 16 children, the two eldest of whom, Atreus and Thyestes, becoming jealous of Chrysippus, who was their father's son by Axioche or the nymph Danais, murdered him with the connivance of Hippodamia, and were expelled by Pelops from the kingdom. Their guilty mother fled to Argolis, where she died. Pelops was held in great veneration after his death, and a sanctuary was dedicated to him in the grove Altis at Olympia.

PEMBROKE, a seaport and county town of Pembrokeshire, Wales, situated on a creek of Milford Haven, 206 m. W. from London; pop. in 1851, 10,107. At the W. extremity of the rocky ridge on which the town stands are the ruins of an ancient fortress, erected in 1092. Pembroke dock is a government naval establishment situated about 2 m. N. W. from the town. The dock yard contains an area of 60 acres, and is enclosed by a lofty stone wall, inside of which are the public offices, &c. There are 12 building slips.

PEMBROKE, Earl of. See Herbert, William.

PEMBROKESHIRE, a county of Wales, occupying the extreme S. W. point of the principality, and bordering on the Bristol and Irish channels; area, 610 sq. m.; pop. in 1851, 94,140. The chief towns are Pembroke, Haverford West, St. Davids, Milford, and Tenby. Milford Haven is the chief port. The coast line is very irregular, being indented with numerous bays and studded with islands. The rivers are of little importance. The surface is generally undulating, with low hills and rich meadows and corn fields. The anthracite coal tract bisects the county. Copper ore is found, slate and coal are worked, and the fisheries are valuable. The county and its towns return 3 members to parliament.

PEMISCOT, a S. E. co. of Mo., in the extreme corner of the state, bounded E. by the Mississippi river; area, 600 sq. m.; pop. in 1860, 2,961, of whom 268 were slaves. Its surface is nearly level, much of it being covered by swamps, the largest of which, Lake Pemiscot, has an area of about 75 sq. m. It was formed in 1851 out of New Madrid co. Capital, Gayoso.

PEMMICAN, a preparation of preserved meat, made by cutting lean meat into thin strips, and, after they are thoroughly dried, reducing the substance to powder and mixing this with melted fat. It is largely used by the northern *voyageurs*, and constitutes an important item in the supplies furnished by the Hudson's bay company to their employees.

PEN, an instrument for writing with a fluid. Pens of some sort have been in use from very ancient times, adapted to the material upon which the written characters were to be impressed. Upon stone or metallic plates gravers of steel served for writing, and such are referred to by Job in speaking of an "iron pen." For the waxen tablets of the ancients a metallic stylus was employed, one end of which was sharpened for marking, and the other was flattened for erasing the marks and smoothing the wax. It was also the practice in ancient times, as among the Chinese at the present day, to paint the letters with a fine hair pencil. Pens of reeds also were made at a very early period for the use of a fluid ink upon papyrus. The reed selected for this purpose is described as small and hard, and about the size of a swan's quill. It was found in Egypt and Armenia; and Cairo and Alexandria were famous markets in which it was sold. Along the shores of the Persian gulf reeds are still collected for this use, and are distributed throughout various parts of the eastern countries, being better adapted to the ink and paper employed in these regions than any other kind of pens. They are prepared by leaving them under dung heaps for several months, which causes them to acquire a mixed black and yellow color, and a smooth and hard surface. The pith is dried up by the heat generated. The introduction of paper rendered necessary pens of finer character, and quills of the goose and swan next came into use, and for extremely fine writing those of other birds, as of the crow, were found well adapted. A great trade grew up in these articles, and continued for several centuries. Poland and Russia were largely engaged in it, and immense flocks of geese were raised in those countries chiefly for their quills. In a single year St. Petersburg has furnished to England over 27,000,000 quills. Germany and the Netherlands have also been large producers of goose quills. From each goose the average number of good quills obtained is only 10 or 12, though sometimes they have amounted to 20. As they are plucked from the wing they are soft and tough, and covered within and without with a thin membrane. They are first sorted according to the length and thickness of the barrel into primes, seconds, and pinions, and are then buried for a short time in hot sand, which dries the outside skin, so that it is easily scraped off, and the inner lining becomes shrivelled and detached. The process is repeated if necessary. This treatment is called, from having been practised in Holland, "dutching." After this the quills are hardened by dipping them into a boiling solution of alum or of diluted nitric acid, which also renders the barrel yellow. A portion of the barbs is then stripped off, and the quills are tied in bundles for the market.—The immense consumption of quills proved the necessity of more durable substitutes. In 1803 Mr. Wise of Great Britain produced pens of steel of barrel form, mounted in a bone case for carrying in the pocket. These were expensive and little used. Mr. Gillott of Birmingham commenced the manufacture about the year 1822, and introduced great improvements in the steel pen, making it of thinner and more elastic steel, and of higher finish and temper. Mr. Perry also was among the first large manufacturers of the article; and by their improvements the cost was so much reduced, that a gross of the pens, now made without the barrel, could be purchased for about the price of one of those made by Mr. Wise. Other makers succeeded, and a great variety of forms of pen were devised to give in the greatest perfection the required elasticity, and the capacity of holding a proper supply of ink, and of shedding it freely when pressed upon the paper. Most of these forms were more curious than useful, and the manufacture has since been chiefly limited to the simpler shapes, such particularly as resemble the form of the old pen cut from the goose quill. The trade centred in Birmingham, which supplies many countries in Europe, as also the principal demand for steel pens in the United States. The number of manufacturers in that city is reported to be 18, and 8 more are engaged in making pen holders. The processes are brought to such perfection, that better pens are now sold at 12 cents the gross than those which were produced in 1821 at a cost of $36 the gross. The prices vary from 4 cents the gross to 75 cents or $1. The total number made in Birmingham has been estimated at not less than 1,000,000,000 pens annually. In the United States several attempts have been made at different times to establish this manufacture; but it has been found almost hopeless to try to compete with the Birmingham manufacturers, and though large sums of money have been expended, the enterprises have generally been abandoned. In New York city a manufactory is in operation, called the Washington medallion pen factory, in which the processes are conducted upon the English plan. The steel sheets imported from Sheffield are, after annealing, cut into strips 3 feet long and 3 inches wide, then cleaned from the scale in dilute sulphuric acid, and rolled down to the required thickness. The ribbons of steel are then punched in a cutter by hand into blanks. These are next pierced by a punch in a hand screw with a hole near the point and where the slit will terminate. They are then annealed by leaving them 24 hours in a pot in the muffle of a furnace. After this they are stamped with their peculiar device, by means of a hammer worked by a treadle so rapidly that one girl may stamp 20 gross in an hour. The blanks, which are still flat pieces, are now shaped by being struck in dies; and after this they are hardened by heating and plunging them into oil. When the oil has partially drained off, they are further cleaned by alkaline washes, and rolling in a revolving drum with sawdust and sand. The tempering is effected by placing several thousand together in an iron cylinder which a boy keeps turning over a fire. By frequent trials it is ascertained when they have been sufficiently treated, and they are then taken out and spread to dry quickly. Another scouring in the revolving drum succeeds, and the color is thus transformed from bluish to nearly a clear white. The pens are next ground on the nib upon emery wheels by girls, who take each one up in a pair of pliers and perform this operation with singular rapidity and exactness, completing about 10 gross in an hour. This, called the "straight grinding," is distinguished from the "cross grinding," which is applied to the back of the pen as this is held in the hand, consuming almost double the time. The slits are next made by cutters working against each other in a screw press, and the roughness thus occasioned is removed by another polishing in the drum, after which the pens are browned or otherwise colored by heating them to the proper temperature in a revolving cylinder over a fire, and immersing them in a solution of lac. The last process is to examine them, reject the imperfect ones, and pack the good ones in small pasteboard boxes for the market.—The manufacture of pens of elastic material furnished with durable points of some extremely hard substance commenced in England with attempts to secure bits of metal to pens made of glass, tortoise shell, and horn. These beginnings led at last to the production of gold pens, the manufacture of which is carried to the highest perfection in New York, so that the only really excellent pen used in Europe is obtained from this country. In 1823 Mr. John Isaac Hawkins, an American by birth, residing in England, imbedded pieces of diamond and ruby in the points of tortoise shell pens, which were softened in water to receive the stones. The same manufacturer, hearing that bits of an extremely hard native alloy of iridium and osmium, sent by Dr. Wollaston to a penmaker to be used for points, had been returned as too hard for working, obtained these for his own experiments, and was the first to produce the famous "diamond points" soldered to gold pens. Mr. Mordan, a pencil case maker in London, also made some gold pens; but they were of little value, being deficient in elasticity. The manufacture of these pens made but slow progress, great skill, the result of long continued experiments, being necessary to produce the exact shape suited for the required elasticity of the pen, and to combine this with the proper size and form of the points. They were moreover costly as well on account of the metal employed as the labor expended in the manufacture. The right to make gold pens was purchased of Mr. Hawkins by Mr. Cleveland, an American clergyman then in England, who on his return induced Mr. Levi Brown, a watchmaker in Detroit, to undertake their manufacture. This was about the year 1835. The experiment was attended with little success. Mr. Brown removed in 1840 to New York, and there introduced the business, which gradually increased in importance as the quality of the pens was improved, and the price diminished by their more rapid production. At first the pens were cut with scissors into shape from a thin flat strip of gold, and a slit being cut in the nib a bit of iridium was soldered to each point separately, and the points were then rounded up into shape with a mallet upon a stick. The inferior pens thus made by hand sold for $5 to $10 each. The first machines, and almost the only important ones in use applicable to the different branches of this work, were invented by Mr. John Rendell, who was employed by Mr. Brown. He continued to make these machines of various forms and of extraordinary perfection from the year 1844, and furnished them to Mr. Bagley and Mr. Barney, who were well known as among the early makers of gold pens. To these inventions is chiefly due the excellence of the gold pens made in this country. Mr. Rendell systematized the process, giving to each workman his peculiar branch, and thus a nicety and certainty of good work were attained by each one which was essential to the perfection of the pen. The processes employed are more numerous and delicate than one not acquainted with the manufacture would readily imagine. In the factory of Mr. Leroy W. Fairchild in New York they are now conducted with the original machines of Mr. Rendell, and the improvements and additions to these made by Mr. Fairchild have materially contributed to the peculiar delicacy, elasticity, and finish of the perfect pen. In 1850 the business had grown to such importance in this establishment, that a steam engine was procured for running the machines, the first application of steam power to this purpose. The number of pens which such a factory may produce depends entirely upon the amount of care and labor spent on each one. Of the more common sorts 900 may be made in a day as readily as 500 in a week of the best. The following is a general description of the different operations in the order in which they follow each other. The alloy of gold and silver of 16 carats fine is melted, and when at the right temperature to produce the peculiar grain that indicates gold susceptible of the greatest elasticity, it is cast in hot ingot moulds in cakes of about 20 oz. each. These are then rolled out into sheets 10 or 12 feet in length and considerably thicker than the finished pens. The sheets are then taken to the stock cutters, and short blanks are punched out from them bearing some resemblance in shape to the pen. Each blank is then notched on the under side of the point by a little toothed wheel, against which the point is held as the pen rests in a seat made for the purpose in the machine. An iridium point, carefully selected with the aid of a microscope from the stock kept on hand (see IRIDIUM), is then laid in the notch; there are sometimes two such points, but generally only one, to each pen. A little borax is used to secure it in its place, while by the jet of a blowpipe the gold is softened around the point and the metals are welded together. The point is then applied to a copper emery wheel and brought to a square even face. The pen is then brightened up by a wash of nitric acid. In what are called the breakdown rolls, which are carried half round by a little lever held in the hand, the blanks are drawn out to the full length of the pen. The rolls take the pen by the point, and as this passes between them a spring set in the under one sinks into the roll, thus guarding the point against the pressure which is applied to the rest of the pen. The rolling is repeated in other rolls, called finishing rolls, of similar construction. This process leaves the pen with no particular elasticity; this is imparted to the lower end by a small planishing hammer worked by the hand, while the pen is held across a little anvil of curved surface. The next operation is to trim the pen, which is done in a finishing cutter, worked by a hand lever, similar to that in which the blanks are punched. This takes off a narrow strip round the margin except at the point. The name of the maker and size and number of the pen are now stamped on the back; and the pen is then ready to be "raised," or bent into the partially cylindrical form. To insure perfect shape and a permanent set to the new curve, it has been found necessary to employ a press of great power and dies of extreme exactness of figure; and this has perhaps proved the most difficult part of the whole process. The lever worked by the foot acts upon another with such increase of power, that the pressure obtained amounts to over three tons. From this the pen goes to the machine known as the "carriage cutting point," where it is nicely adjusted across a horizontal axis, which is then turned over, bringing the iridium point upon the edge of a thin copper emery wheel kept in rapid rotation. A slit is soon made through the iridium, dividing it into two points. In another lathe carrying a circular saw only half an inch in diameter, made of the finest steel and provided with very sharp teeth, the slit is extended up into the gold as far as is necessary. Burnishing the nibs, which succeeds, spreads the gold, partially filling the vacant space of the slit, and the proper elasticity is given to the lower part of the pen by hammering. The edges of the slit are next smoothed and trimmed by running into it the edge of a very thin wheel of tin fed with the finest emery. By the same operator the set is given to the nibs by bending them in with the fingers till they have each a uniform and precise curve. The pen being now held in a steel holder that leaves only the point projecting, this is applied to the surface of a revolving cylinder of copper fed with emery, and the iridium is chamfered on the back and ground on the under side into a somewhat hooked or beaked shape; the edges of the nibs are also smoothed and rounded. In another suitable holder the pen is placed to be honed or stoned on the back or convex side preparatory to polishing, and in still another the lower or concave side is exposed for the same purpose. Similar holders are used for the polishing, which is done on wheels covered with felt, and supplied with rotten stone. An application of lye is now made to remove the oil, and the pen is completed by roughening the concave surface of the nibs to prevent the ink flowing too freely. The finisher now takes the pen, readjusts the nibs, opens the slit again on the slitter, and smooths and polishes the points by delicately touching them to the polishing wheel. This work requires much skill and experience. Finally the head of the establishment submits each pen to thorough trial by writing with it, and otherwise proving its perfection. The pens are made chiefly of 9 sizes, ranging from $\frac{11}{12}$ of an inch to 2 inches in length, and the larger sizes in long nibs and short nibs. Some barrel pens also are made, the longest being about $2\frac{1}{4}$ inches long. In New York city there are 7 or 8 factories devoted to this manufacture, some of which produce however only cheap pens. In Brooklyn, N. Y., there is one factory; in Brooklyn, Conn., 2; in Haydensville, Mass., one: and in Cincinnati, one. In the last are made the pens of Dawson, Warren, and Hyde, which rank among the best in the market.—Pens have also been made of hardened gutta percha, and of caoutchouc similarly treated; but they have not proved of much service. The so called "Protean fountain pen" contains a supply of ink in its hollow handle, and the tube which holds it extends nearly to the point, the pressure upon which in writing causes the ink to ooze down to it just as it is required. These pens are furnished with holders suitable for carrying in the pocket, and thus are always at hand for use with their own supply of ink. The introduction of metallic pens has not lessened the price or the production of goose quills.

PENANCE (Lat. *pœnitentia*, repentance), a penalty accepted or self-imposed by way of satisfaction and token of sorrow for sin. Ecclesiastical penances were inflicted under the Jewish dispensation, and we read in the Old Testament of individuals and whole cities or peoples fasting and performing other acts of humiliation. The idea of penance seems to have been familiar even to heathen nations. The revolting austerities practised by the Hindoo devotees, if they can properly be called penances, are among the most striking examples of this class. In the early Christian church penances were of 3 sorts, secret, public, and solemn. The first consisted of such actions as are commonly imposed by confessors at the present day, as for instance the recitation of certain prayers. Public penance was in use from the earliest days of the church, and accompanied the readmission to communion of persons who had been excluded from it for grievous offences. It was frequently very severe, and the penitents, beside being required to kneel in worship while the rest of the faithful were permitted to stand, had to make a public confession of their sins in the church. Of solemn penance, which seems to have originated about the middle of the 3d century, or soon after the rise of the Novatian heresy, there were 4 degrees. The first was that of the weepers, who remained at the door of the church clad in sackcloth and ashes, and begged the prayers of the faithful as they passed in. The 2d was that of the listeners, who were permitted to enter the vestibule to hear the reading of the Scriptures and the sermon, but went away before the mass of the catechumens commenced. The prostrate, who belonged to the 3d class, knelt in the space between the doors of the church and the *ambo*, or desk where the epistle and gospel were read. They were dismissed at the same time with the catechumens. The 4th degree of penitents were the *consistentes* (literally, co-standers), who stood with the faithful before the altar and remained throughout the service, but might neither make oblations with them nor receive the eucharist. During the term of penance expressions of joy were to be laid aside, gay dresses put off, and marriage, feasting, bathing, and various bodily gratifications abstained from. The men were to cut their hair and beards, and the women to appear with dishevelled locks. The penitents were also expected to abound in good works, and be present, as far as it was permitted them, at every religious assembly. The collection of canons which appointed the time and manner of penances for different sins was called the Penitential. Whether priests and deacons were obliged to submit to the same ceremonies of reconciliation as laymen is not certain. The final readmission of penitents to communion was attended with certain forms, and in ordinary cases the officiating minister was a bishop, though the inferior clergy could admit a penitent from a low degree into a higher one. In the eastern church, the ceremonies of solemn penance were retained until about the close of the 4th century, and in the western church until near the end of the 7th. It gradually became customary for the bishops to commute the canonical penances for pious works more agreeable to the spirit of the age, such as pilgrimages, works of charity, and alms deeds, and these in turn were exchanged for indulgences. (See INDULGENCE.)—In the Roman Catholic church, penance is also the name of one of the 7 sacraments instituted for the remission of post-baptismal sins. It consists of 3 essential parts, contrition, confession to an authorized priest, and absolution, to which may be added a disposition on the part of the penitent to make satisfaction to God and man for his offences. A slight penance by way of satisfaction is always enjoined upon the penitent by the confessor; and though a willingness to receive it is a requisite disposition on the part of the former, the neglect to fulfil it does not invalidate the sacrament. (See CONFESSION, AURICULAR.)

PENANG, PULO PENANG ("Areca island"), or PRINCE OF WALES'S ISLAND, an island belonging to Great Britain, situated in the strait of Malacca, extending from lat. 5° 16′ to 5° 30′ N., and from long. 100° 9′ to 100° 20′ E.; extreme length 15 m., breadth 12 m.; area, 160 sq. m.; pop. in 1855, 89,860. Georgetown is the capital, and seat of government of the British straits settlements, which comprise Penang, the province of Wellesley, Malacca, and Singapore. The channel dividing the island from the mainland is navigable for large vessels, and varies in breadth from 2 to 7 m., the harbor of Georgetown being the N. part of it. The form of Penang is very irregular, and the coasts are bold and indented by several bays. There are many small streams, but no river of any great size on the island. The surface is uneven, and intersected by a mountain range, the highest point of which, West hill, is 2,713 feet above the level of the sea. These heights terminate on the E. and W. in level plains, and the shores are bordered by a belt of cocoanut trees; that on the E. side being more fertile than the W. plain, which is swampy. The whole of the country where not cultivated is densely wooded, and the forests extend to within a short distance of the summits of the mountains, which terminate in rocky peaks. The climate is, upon the whole, healthy. Tin ore is said to be abundant in the mountains, but the mines have never been worked to any great extent. Cloves, tea, cotton, tobacco, coffee, sugar, nutmegs, rice, and numerous tropical fruits and vegetables are grown; and the forests yield timber of a superior quality. Buffaloes, horned cattle, and pigs are abundant, and there are some goats, but sheep do not thrive. There is a bank of pearl oysters on the E. coast. The original inhabitants were a few Malays; but since the British have been in possession of the island, people from Hindostan, Burmah, Siam, China, and all the neighboring islands have settled upon it, nearly ½ of the whole being Chinese. In 1854 the total value of the imports was $2,906,200.—The island of Penang formerly belonged to the king of Queda, but was given by him in 1785 as a marriage portion with his daughter, who married Capt. Light, the master of a British ship trading in the straits of Malacca. The English East India company acquired possession of it by purchase from Light, and appointed him governor; and afterward, in consideration of an annual income paid to the king, the sovereignty of the island and the opposite coast was ceded to them.

PENATES (Lat. *penus*, inmost), the household gods of the Romans, who dwelt in the innermost parts of the house, and were the guardians of the family. They were of two kinds, private and public. The former had always their place at the hearth. In their honor a perpetual fire was kept burning, and at the departure or return of any member of the household, the Penates were saluted in the same manner as the other dwellers in the house. The Lares are probably to be numbered among the Penates, although evidently not the only Penates, as a family rarely had more than one Lar, while the Penates are never spoken of in the singular. Varro says that the number and names of the latter were indefinite. The public Penates of Rome, depicted as two young men holding lances in their hand, had a sanctuary near the centre of the city in a spot called *sub Veliis*. Sacrifices were made to them by generals when departing on their campaigns, and by consuls, prætors, and dictators when they gave up their office.

PENCIL, a delicate brush made from the fine hairs of various animals, especially the camel, badger, squirrel, &c., and used by artists for laying on their colors. The hairs, being selected, are arranged in a little roll, and a string is tightly bound around the end consisting of the roots. The points are also temporarily bound together. The roll is then introduced into the large end of a quill tube, which has been softened by moisture, and is pushed through till the larger end is arrested by the narrowness of the aperture. As the quill dries, the increased pressure caused by its contraction holds the hairs securely in their place, the points projecting through to make the pencil or brush; but it is essential that the pressure should not be so great as to make the points spread apart when these are untied. The finest pencils require very careful selection and arrangement of the hairs, and much experience for obtaining a round and even point. The holder of the pencil is made by inserting a light stick into the large end of the quill. The quills used vary in size according to the kind of pencil, from that of the wing of the crow to that of a swan; larger pencils than these are made by the use of a socket of sheet tin.—A lead pencil is a sort of crayon used in drawing, made of slips of the mineral graphite or plumbago, as described in the article GRAPHITE. Colored pencils are also prepared by the use of various coloring substances in the place of graphite, as reddle, a red ochre for red pencils, &c. The coloring substance is reduced to powder, formed into a paste with gum Arabic, and moulded into hollow cylinders of wood. Pencils for the slate are strips of slate itself made round and smooth. Artificial ones have been made of the powder of slate moulded with vulcanized India rubber; but pencils into which this material enters have always the unpleasant odor of the vulcanized rubber.

PENDLETON. I. A central co. of Va., enclosed between two ranges of the Alleghanies, and intersected by the south branch of the Potomac river and two of its tributaries; area about 800 sq. m.; pop. in 1860, 6,165, of whom 244 were slaves. Its surface is mountainous and covered with forests, and the soil not very fertile. The productions in 1850 were 109,838 bushels of Indian corn, 44,137 of wheat, 29,930 of oats, 7,664 tons of hay, 26,107 lbs. of wool, and 69,306 of butter. There were 20 grist mills, 40 saw mills, 7 wool-carding mills, 7 tanneries, 12 churches, and 225 pupils attending public schools. Capital, Franklin. II. A former district of S. C., in the N. W. corner of the state, now included in the two districts of Pickens and Anderson. III. A N. co. of Ky., bordered N. E. by the Ohio river, and intersected by the Licking; area, 300 sq. m.; pop. in 1860, 10,443, of whom 424 were slaves. It has an undulating and well wooded surface and fertile soil. The productions in 1850 were 429,855 bushels of Indian corn, 44,207 of oats, 253,827 lbs. of tobacco, 20,166 of wool, and 253,827 of butter. There were 8 grist mills, 2 saw mills, 14 churches, and 880 pupils attending public schools. It is intersected by the Covington and Lexington railroad, which passes through the capital, Falmouth.

PENDLETON, EDMUND, an American statesman and jurist, born in Virginia, Sept. 9, 1721, died in 1803. He began his career as an apprentice in the clerk's office of Caroline co., in 1740 was made clerk of the county court martial, and in 1741 was licensed to practise law. In 1751 he became one of the county justices, and in the following year was elected to the house of burgesses. These posts he continued to fill until 1774, at which time he presided in Caroline court, and discharged the trust of county lieutenant. He was elected to the colonial convention of 1774, consequent on the Boston port bill, and chosen by that convention to the first congress. He accordingly attended in Philadelphia in 1774, and again in 1775, in company with Peyton Randolph, George Washington, Patrick Henry, Benjamin Harrison, and Richard Henry Lee. In 1775 he presided over the colonial convention, and was appointed president of the committee of safety. In May, 1776, he again presided in the convention, and drew up the celebrated resolution of that body, instructing the delegates from Virginia to propose in congress a declaration of independence. After the inauguration of the commonwealth he was called to preside over the first house of delegates, and was appointed by that body, in conjunction with Chancellor Wythe and Mr. Jefferson, to revise the colonial laws. In March, 1777, by a fall of his horse, he received an injury of the hip joint which made him a cripple for life. In the same year he was unanimously reëlected speaker of the house of burgesses. On the organization of the chancery court that year he was again unanimously elected its president; and when, in 1779, the court of appeals was constituted, he also became its president. This last responsible position he held till his death. He was elected to the state convention of 1788, in which was to be considered the proposed constitution of the United States, and was appointed to preside over its deliberations. In those deliberations he took a leading part, and, by a masterly advocacy of the great national compact, justified the high encomium of Jefferson: "Taken all in all, he was the ablest man in debate I ever met with."

PENDLETON, HENRY, an American jurist, born in Virginia about the middle of the 18th century, died in South Carolina in 1788. He emigrated to South Carolina before the revolution, and in April, 1776, was elected to the judiciary of the colony. When the state was overrun by the British in 1780, he took up arms on the patriotic side, and served until the close of the war, participating in the final battle of Eutaw Springs. In 1782 he resumed his judicial duties, and was the author of the county court act of South Carolina. In 1785 he was one of the 3 judges appointed to make a digest of the laws of the state, and in 1788 he was a member of the convention which ratified the constitution of the United States.

PENDULUM. See CLOCKS AND WATCHES, and MECHANICS, vol. xi. p. 324.

PENDULUM, BALLISTIC. See GUNNERY.

PENELOPE, a gallinaceous bird. See GUAN.

PENELOPE, the wife of Ulysses and mother of Telemachus. She was the daughter of Icarius, and having many suitors, her father promised to give her to the one who should conquer in a foot race. The victor was Ulysses, and when her father urged her to remain with him and not accompany her husband to Ithaca, the hero gave her leave to do as she pleased. She indicated her resolution to go with him by covering her face with a veil to hide her blushes, whereupon Icarius erected a statue of Modesty on the spot. While Ulysses was at the siege of Troy, she was surrounded by many importunate suitors, whom she deceived by declaring that she must finish a robe which she was weaving before she could make up her mind. But she unravelled each night all that she had done during the day; and when at last the suitors discovered her stratagem, Ulysses opportunely arrived after 20 years' absence and killed them all. She was regarded as a model of a chaste, faithful, and industrious wife, though some writers later than Homer give her a very different character, alleging that by Mercury or by all the suitors together she became the mother of Pan, and was repudiated by her husband on his return from Troy.

PENGUIN, a sub-family of web-footed, imperfectly winged birds, inhabiting the seas around the rocky coasts, islands, and ice fields of the southern Pacific ocean, and the extreme portions of South America and Africa—the *manchots* of the French. Some of the earlier writers give this name to the auk (*alca*, Linn.) of the arctic seas, but it will here be restricted to its more modern application to the antarctic sub-family.—In the genus *aptenodytes* (Forst.) the bill is slender, longer than the head, compressed on the sides, and slightly curved at the point, which is acute; the upper mandible is clothed with short close-set plumes as far as the nostrils, which are in a lateral groove in the middle of the bill, and the lower is covered with a smooth naked skin; the wings are very small, fin-shaped, without quill feathers, having only short imbricated plumes with flattened shafts, and are unfit for flight; the tail is very short, flat, of narrow rigid feathers; the tarsi very short and flattened; the toes short and depressed, the anterior united by a web, and the hind one very small and almost entirely connected to the inner side of the tarsus; the claws large, flat, and slightly curved. As in the other genera, the breast bone is deeply incised behind on each side; the scapula is large and broad, and flat behind; the bones of the forearm and arm are very flat, the former making with the latter a rather obtuse angle; the feet are very far back, and the whole posterior surface of the tarsus touches the ground when the bird stands; the bones are heavy, filled with marrow, and without air cavities. The Patagonian penguins of Shaw and Pennant were different birds to which the same name had been given; to avoid confusion G. R. Gray calls one the emperor and the other the king penguin, or *A. Forsteri* and *A. Pennantii*. In the former the length is 50 inches and the bill 5, in the latter 44 and 4½; the general color of both is slate above and white below, with the head and throat black, the latter in the first species divided in front by a point of the white feathers of the chest, and in the 2d ending in a blunt point; there is an orange yellow stripe on the sides of the head, descending and passing gradually in the former and suddenly in the latter into the white of the chest. The plumage is soft and close, with a silvery gloss below, this part being used by fur dealers for tippets and collars; the neck is short and stout, the skin hard and thick, and the belly loaded with fat. They are found in immense numbers about the straits of Magellan, the Falkland islands, and the western group of the S. Pacific islands; they group themselves, when on shore (which is only during the breeding season), in regular ranks like soldiers, classed strictly according as they are young, moulting, incubating, or with perfect plumage, those of one class not being permitted to intrude upon another. They present a strange appearance as they sit upright; they employ their wings like anterior limbs on land, crawling along on the belly pretty fast to and from their breeding places in the manner of quadrupeds; they are excellent swimmers, and fly swiftly under water, using their wings as fins, and breasting the most violent waves; though stupid and rather helpless birds, they often boldly attack intruders on their breeding places, inflicting severe wounds with their sharp bills; the food is principally animal, consisting of fishes and crustaceans. The eggs are laid on the ground or in holes, and are hatched by keeping them close between the thighs; the males collect food for the females, which become very fat during incubation; the young birds also get very fat before they quit the breeding places, which are covered with excrements and remains of dead birds, accumulated into heaps of guano during many successive years. The flesh of the penguin, though black and fishy, is considered eatable by hungry mariners.—In the genus *catarrhactes* (Briss.) the bill is moderate, strong, compressed, grooved on the sides, and slightly hooked at the tip, with the end of the lower mandible truncated; the tail is long, of narrow rigid feathers; the toes are long and strong. Several species are described, inhabiting in small parties the southern ocean, in open water or on fields of ice, sometimes more than 800 m. from land; they go to the shore only in the breeding season; they are more active, if possible, than the preceding genus, and swim and dive with great quickness; their cries are harsh and discordant, resembling the bray of a donkey. The crested penguin (*C. chrysocoma*, Gmel.) is as large as a stout duck, black above and white below, with a yellowish white crest on each side of the head, and red bill and feet; it inhabits the vicinity of the Falkland islands and Tasmania.—In the genus *spheniscus* (Briss.) the bill is much as in the last, with a more hooked tip and the nostrils uncovered in the middle of the lateral groove; the tail and tarsi are very short, and the toes and claws long. The species are few, found about the rocky islands of the southern ocean, and on the W. coast of South America and Africa; the habits are the same as in the preceding genera. The Cape or jackass penguin (*S. demersus*, Linn.), from the Cape of Good Hope, is black above and white below, with a white stripe over the eyes, the throat black, and a black line on the breast continued along each flank; the bill is brown, with a white band across the middle of its length; the length is 21 inches; its common name is derived from the resemblance of its voice to a bray. It comes to the surface of the water to breathe with such a spring and dives again so quickly, that it seems more like a fish leaping for sport than a bird; it seems perfectly at home in this element. Humboldt's penguin (*S. Humboldti*, Meyen), common on the coast of Peru, resembles the last, but is larger; it is readily tamed, and follows its master about like a dog. The Magellanic penguin (*S. Magellanicus*, Forst.) is 2 feet long, and sometimes weighs 20 or 30 lbs.; the general color is black above and white below, with white streaks on the sides of the head and a black band on the breast; it is found about the southern parts of South America, and is well known to navigators, who have long been in the habit of invading its breeding places, and killing the birds for food or for sport.

PENN, Granville, an English author, born Dec. 9, 1761, died at Stoke Park, Buckinghamshire, Sept. 28, 1844. He was the grandson of William Penn, served for a time as chief clerk in the British war office, and by the death of his brother (1834) came into the possession of the family estates. He wrote "Critical Remarks on Isaiah vii. 18;" "Remarks on the Eastern Origination of Mankind, and of the Arts of Cultivated Life;" "A Comparative Estimate of the Mineral and Mosaic Genealogies;" "Memorials of the Professional Life and Times of Admiral Sir William Penn" (London, 1833), and many other works, the most important being a translation of the New Testament with annotations under the title of "The Book of the New Covenant" (2 vols., London, 1836).

PENN, Sir William, an English admiral, born in Bristol in 1621, died in Wanstead, Essex, Sept. 16, 1670. He early entered the naval service, and before he was 32 years old had gone through the grades of captain, rear admiral of Ireland, admiral to the straits, vice-admiral of England, and general. He was one of the commanders in the expedition that took Jamaica from the Spaniards in 1655, and on his return in the same year was elected member of parliament from Weymouth, but was for a time confined in the tower on the charge of having absented himself from his command without leave. In 1660 he was made commissioner of the navy, governor of Kinsale, vice-admiral of Munster, and a member of the council of that province. He was also knighted. Entering the naval service again in 1664, he was captain-commander under the duke of York in the victory gained over the Dutch off Lowestoffe in 1665. In 1666 he left the naval service, but retained his other offices until 1669, when he went into retirement altogether. He was the author of several tracts designed to improve the naval service.

PENN, William, an English Quaker, the founder of Pennsylvania, born in London, Oct. 13, 1644, died at Ruscombe, Berkshire, July 30, 1718. He was the son of Admiral Penn, who, notwithstanding his hostile professional relations with the Dutch, took to wife a woman of that nation, Margaret, daughter of John Jasper, a merchant of Rotterdam, to whose noble and religious character and judicious government the son owed many of the excellent traits by which he was through life distinguished. William Penn received his first education at the free grammar school of Chigwell, Essex, where he experienced strong religious impressions. When only 11 years of age he was the subject of deep exercises of spirit, which in the language of the time are represented almost as miraculous. While alone in his chamber he fancied himself surrounded by an external brightness which seemed to answer to a mysterious motion within, and he regarded himself as called by this experience to a consecration of heart and life to the service of God. At the age of 12 he was removed from Chigwell to receive private instruction at home, and 3 years later entered Christchurch college, Oxford, where he numbered among his companions John Locke. While in college, Penn, through the influence of Thomas Loe, became a convert to Quakerism, and not only refused to conform to the worship of the established church or to wear the surplice of a student, which he considered a relic and emblem of popish superstition, but, with some of his companions who had embraced his principles, assaulted several of the students in public and stripped from them their robes. For this outrage he was expelled, and on his return home his father, a worldly and ambitious man who was aiming at a peerage, and was greatly vexed and mortified by his son's fanatical associations and conduct, beat him and drove him from the house. A reconciliation however soon took place, and in 1662 the admiral sent his son to France, in hopes that the gayety of Paris might counteract the soberness of his Quakerism. The youth, however, had no taste for the dissipation of the French capital, and preferred to study theology at Saumur with the famous Calvinistic divine and professor Moses Amyrault. After travelling as far as Turin he was recalled home by his father in 1664, and is thus mentioned by Pepys in his diary, under date of Aug. 30: "Mr. Penn, Sir William's son, is come back from France, and come to visit my wife; a most modish person, grown, she says, a fine gentleman." Without losing his religious seriousness, he had acquired on the continent more polish and courtesy and liveliness of manners. In compliance with his father's wishes he entered as a student of law at Lincoln's Inn, but shortly after, just as he became of age, was driven from London by the great plague of 1665. Under the influence of that terrible visitation his religious impressions acquired redoubled force; and when his father returned from sea in 1666, he found his son more demure in looks and formal in language than ever before. He made another effort to change these tendencies by sending the young man to Ireland, and committing to him the management of two large estates which he owned in the county of Cork. Penn readily assumed this charge, and executed it to the entire satisfaction of his father; but encountering again at Cork his former teacher, Thomas Loe, he was induced to attend Quaker meetings, at one of which, Sept. 3, 1667, he was apprehended with others and carried before the mayor, on a charge of attending unlawful assemblies. Refusing to give bonds for his future good behavior, he was sent to prison. He wrote, however, to the lord president of the council of Munster, with whom he was personally acquainted, who procured his immediate discharge. From this time he identified himself with the Quakers in every thing except costume, and on returning to England soon after became involved in disputes with his father, who was greatly shocked at his departure from established forms, but finally offered to compromise the matter by tolerating every other peculiarity if his son would only agree to remove his hat in his presence and in that of the king and the duke of York. Penn before answering retired to his chamber, and after deliberation and prayer declared that he could not remove his hat by way of compliment to any one. His father at once turned him out of doors. This persecution confirmed Penn still more in his Quakerism, and he soon became a prominent preacher at the meetings of the Friends. Through the influence of his mother his father's indignation was so far softened that he permitted his son to return home, and used his interest with the government to relieve him from the persecutions to which his attendance at the prohibited meetings frequently subjected him. In 1668 Penn made his first appearance as an author by issuing a crude and acrimonious treatise entitled "Truth Exalted, in a short but sure Testimony against all those religious Faiths and Worships that have been formed and followed in the darkness of Apostasy; and for that Glorious Light which is now risen and shines forth in the Life and Doctrine of the despised Quakers as the alone good old way of Life and Salvation. Presented to Princes, Priests, and People, that they may repent, believe, and obey. By William Penn, whom Divine Love constrains in an holy contempt to trample on Egypt's glory, not fearing the King's wrath, having beheld the Majesty of Him who is invisible." This was followed by a considerable number of tracts on similar topics, which with his other writings have been collected and published by Joseph Besse (2 vols. fol., London, 1726). In 1668 he published "The Sandy Foundation Shaken," an attack upon "those so generally believed and applauded doctrines of one God subsisting in three distinct and separate persons; of the impossibility of God's pardoning sinners without a plenary satisfaction; and of the justification of impure persons by an imputative righteousness." This work caused a great excitement by its bold opposition to the commonly received doctrine of the Trinity, and Penn was apprehended and imprisoned in the tower for 9 months, during which he wrote his principal and most popular theological work, "No Cross, No Crown; a discourse showing the Nature and Discipline of the Holy Cross of Christ." By the interference of the duke of York he was at length released and permitted to live in his father's house, though the admiral would not admit him to his presence. He had however such confidence in his son's integrity, that he gave him through his mother a commission to go again to Ireland to look after his estates. On his return Penn was reconciled to his father, and lived with him on good terms till the latter's death in Sept. 1670, though before that event the son had once more been committed to prison with another Quaker for preaching in the streets. He was not, however, convicted of the charge, the jury, after a remarkable trial (during which they were kept for two days and nights without food, fire, or water), bringing in a verdict of not guilty, for which each juryman was fined 40 marks and sent to Newgate; while Penn and his companion were also fined and imprisoned for contempt in wearing their hats in presence of the court. They appealed to the court of common pleas, where the decision of the lower court was reversed, and the great principle of English law established that it is the right of the jury to judge of the evidence independent of the dictation or direction of the court. The admiral bequeathed to his son an estate of £1,500 a year, with large claims against the government; and thenceforth the cares of business and the duties of his lay ministry seem to have equally divided the time of Penn. In March, 1671, while preaching in a meeting house in London, he was arrested and committed to the tower, and was soon afterward tried under the conventicle act, but acquitted for want of testimony. The magistrates, however, required him to take the oath of allegiance, which he refused to do from conscientious scruples about swearing, and was consequently sentenced to Newgate for 6 months. While in prison he wrote and published 4 treatises, one of them entitled "The great Case of Liberty of Conscience," which is a good comprehensive statement of the principle of religious toleration, then so little understood. On regaining his liberty he made a tour in Holland and Germany, interceding with the rulers of those countries in behalf of the persecuted Quakers, and on his return home in the beginning of 1672 married Gulielma Maria Springett, daughter of Sir William Springett, and went to reside at Rickmansworth in Hertfordshire. The next few years were devoted to preaching and to defending by his pen the doctrines of the Quakers from various assailants, in reply to whom he published a numerous series of laborious tracts and books. In 1674 his attention was called to the Quaker colonies in New Jersey by a dispute between Fenwick and Byllinge, both Quakers, about their proprietary rights in the colony. The case being submitted to Penn's arbitration, he decided in favor of Byllinge, who subsequently, being too much embarrassed to improve his property, made it over to Penn and two of his creditors as trustees. Penn immediately engaged with zeal in the work of colonization, and at length in 1681 obtained from the crown, in payment of a debt of £16,000 due to his father, a patent for the territory now forming the state of Pennsylvania. The charter vested the perpetual proprietaryship of this vast region in him and his heirs, on the fealty of the annual payment of two beaver skins. He designed at first to call his territory New Wales, and afterward suggested Sylvania as applicable to a land covered with forests; but the secretary who made out the patent insisted on prefixing "Penn" to Sylvania. Penn offered him 20 guineas to leave off his name, and, the offer being refused, complained to the king, who insisted that Pennsylvania should be the designation, in honor, as he said, of his late friend the admiral. In Feb. 1682, Penn became, with 11 others, a joint purchaser of East Jersey, which was already a flourishing colony. Aided by the advice of Sir William Jones, and of Henry, the brother of Algernon Sidney, he drew up a liberal scheme of government and laws for his colony, and in Aug. 1682 embarked for the Delaware, reaching that river after a voyage of 6 weeks. He was received by the settlers with great enthusiasm, and after several meetings for conference and treaties with the Indians, he held his famous treaty with them under a large elm tree at Shackamaxon, now Kensington, probably on the last day of Nov. 1682. A numerous assembly of the Delawares, Mingoes, and other Susquehanna tribes met on this occasion, and formed with the Quakers a treaty of peace and friendship, the only treaty, says Voltaire, "never sworn to and never broken." Soon afterward he laid out the plan of Philadelphia, to which he gave its name in the hope that brotherly love might characterize its inhabitants. He purchased the land where the city stands of the Swedes, who had purchased it of the Indians. He now devoted himself zealously to his duties as governor, and made treaties with 19 Indian tribes; and so long as any of the aborigines remained in Pennsylvania or its neighborhood, their traditions bore testimony to the strong impression which the justice and benevolence of Mignon as the Delawares called him, or of Onas as he was styled by the Iroquois, made on their savage hearts. Penn visited New York and New Jersey; and after meeting with the general assembly of the province at New Castle in May, 1684, he intrusted his government to a council, and in August terminated his first visit to America by sailing for England, leaving behind him a prosperous colony of 7,000 people. During his absence the Quakers had suffered severe persecution in England, and Penn's first care was to intercede in their behalf with the king, from whom he obtained the promise of entire relief for them at an early period. Charles II. died Feb. 11, 1685. James II., who succeeded, had been the pupil in naval affairs of Penn's father, and was his own intimate friend. Penn took lodgings at Kensington to be near the court, upon which he constantly attended, and where he had such influence that his house was thronged by hundreds of suitors asking his intercession in their behalf. His intimacy with the king led to foolish suspicions that he was secretly a Jesuit, and in April, 1685, he published a pamphlet entitled "Fiction Found Out," to rebut the charge. In 1686, partly through his influence, a proclamation was issued by the king and council for the release of those imprisoned on account of religion, and upward of 1,200 Quakers were set free. This was followed in April, 1687, by a proclamation declaring liberty of conscience to all, and removing all tests and penalties. Penn meanwhile made a tour on the continent, during which by order of the king he had a conference with William, prince of Orange, whom he endeavored to convert to his views of universal toleration. Soon after the revolution of 1688, and the accession of William to the throne of England, Penn was called before the council to answer to a charge of treason; but no evidence appearing against him, he was discharged. Soon afterward, a letter from the exiled James requesting him to come to France having been intercepted, he was again arrested and brought before the council in presence of King William; but after a long examination, in which he declared his friendship for James though he did not approve his policy, and said he could not prevent him from writing to him, he was discharged. A third time, in 1690, he was arrested on a charge of conspiracy, tried by the court of king's bench, and acquitted. But in the following year the charge was renewed by an informer named Fuller, whom the house of commons afterward branded as a cheat, a rogue, and a false accuser; and to avoid arrest he concealed himself, though not very closely. Meantime Pennsylvania had been greatly disturbed by civil and religious quarrels, and such representations of the state of the colony were made in England, that in Oct. 1692 the king and queen deprived Penn of his authority as governor, and directed Gov. Fletcher of New York to take upon himself the administration of Pennsylvania. Powerful friends, among them Locke, Tillotson, and the duke of Buckingham, now interceded in his behalf with the king; and he had a hearing before the council on the charges against him, and was honorably acquitted in Nov. 1693. Shortly afterward, in Feb. 1694, his wife died, and he bore testimony to her virtuous life and Christian death in "An Account of the Blessed End of my dear wife Gulielma Maria Penn." Within two years he married a second wife, Hannah Callowhill, a Quaker lady. His government was restored to him in Aug. 1694; and in Sept. 1699, he sailed on a second visit to America, accompanied by his wife and daughter. He found the colony in a prosperous condition, its troubles having subsided, and was warmly received by the people. He immediately gave his earnest attention to various reforms, and especially to the amelioration of the condition of the Indians and negroes. His plans, however, were arrested by tidings from England that a measure was pending before the house of lords for bringing all the proprietary governments under the crown. This led him to return to England in 1701. One of his last official acts before he embarked was to make Philadelphia a city by a charter signed Oct. 25, 1701. Soon after his arrival in England the project of bringing the proprietary governments under the crown was dropped. For several years after this he was involved in great trouble by the affairs of Pennsylvania, where his son, whom he had sent there as his representative, had disgraced him by vicious and riotous conduct, while his trusted agent in the colony, a Quaker named Ford, proved dishonest and left to his executors false claims against Penn to a very large amount. To avoid extortion Penn suffered himself to be committed to the Fleet prison in 1708, where he remained a long time, till he was released by the assistance of his friends, who compounded with his creditors. Wearied at length with the trouble and expense of his government, he had in 1712 made arrangements for the transfer to the crown of his rights as proprietor for £12,000, when he sustained repeated shocks of paralysis; and though he lived 6 years longer, he never regained his mental vigor, and for much of that period was deprived of memory and of the power of motion. He was interred in Jordan's burial ground, near the village of Chalfont St. Giles, in Buckinghamshire. —The reputation of William Penn in his own day did not escape suspicion and censure. The extraordinary mingling of Quaker simplicity and court influence which marked his life gave rise to many imputations upon his character, which have been revived in the present day with much force and pertinacity by Lord Macaulay in his "History of England." Admitting that Penn was without doubt a man of eminent virtues; that he had a strong sense of religious duty and a fervent desire to promote the happiness of mankind; that on one or two points of high importance he had notions more correct than were, in his day, common even among men of enlarged minds; and that he will always be mentioned with honor as a founder of a colony who did not in his dealings with a savage people abuse the strength derived from civilization, and as a lawgiver who, in an age of persecution, made religious liberty the corner stone of a polity, the distinguished historian alleges that "his writings and his life furnish abundant proofs that he was not a man of strong sense. He had no skill in reading the characters of others. His confidence in persons less virtuous than himself led him into great errors and misfortunes. His enthusiasm for one great principle sometimes impelled him to violate other great principles which he ought to have held sacred. Nor was his integrity altogether proof against the temptations to which it was exposed in that splendid and polite, but deeply corrupted society with which he now mingled. . . . . Unhappily it cannot be concealed that he bore a chief part in some transactions condemned, not merely by the rigid code of the society to which he belonged, but by the general sense of all honest men. He afterward solemnly protested that his hands were pure from illicit gain, and that he never received any gratuity from those whom he had obliged, though he might easily, while his influence at court lasted, have made £120,000. To this assertion full credit is due. But bribes may be offered to vanity as well as to cupidity; and it is impossible to deny that Penn was cajoled into bearing a part in some unjustifiable transactions of which others enjoyed the profits." Among the transactions to which Macaulay here alludes was an attempt to persuade Dr. Hough, president of Magdalen college, Oxford, to comply with the wishes of King James in a matter where compliance would have involved a violation of his official oath, by holding out to him the bait of a bishopric. But Dr. Hough himself, in his account of the conversation with Penn, intimates that the Quaker was only speaking in jest—"had a mind to droll upon us." Another and more serious charge is that Penn submitted to be made an agent of the rapacious maids of honor of the royal court to extort money for pardons from the relatives of some young girls at Taunton who were implicated in Monmouth's rebellion. The only foundation for this charge is a letter relating to the transaction written by the earl of Sunderland, which begins thus: "Mr. Penne, her majesty's maids of honor having acquainted me that they design you and Mr. Walden in making a composition with the relations of the maids of Taunton;" and Macaulay assumed without hesitation that the person to whom it was addressed was William Penn. But it has been recently proved by the regis-ters of the privy council, that at this very time a certain George Penne was engaged as a pardon broker at Taunton, and it is most probable that the letter was addressed to him rather than to the respectable and influential Quaker. In the edition of 1858, Macaulay considers the strictures on his previous statements, and says: "If I thought that I had committed an error, I should have, I hope, the honesty to acknowledge it; but after full consideration, I am satisfied that Sunderland's letter was addressed to William Penn."—See "Life of William Penn," by George E. Ellis, in Sparks's "American Biography," 2d series, vol. xii. (Boston, 1852); Hepworth Dixon's "Life of Penn" (new ed., London, 1856); and "Inquiry into the Evidence of the Charges brought by Lord Macaulay against William Penn," by J. Paget (Edinburgh, 1858).

PENNANT, THOMAS, LL.D., an English naturalist and antiquary, born in Downing, Flintshire, June 14, 1726, died there, Dec. 16, 1798. He was educated at Wrexham and at Oxford. At the age of 12 he was presented with the "Ornithology" of Francis Willughby, the reading of which inspired him with a taste for natural history. An account which he wrote of an earthquake felt in Flintshire, April 2, 1750, appeared without his knowledge in the "Philosophical Transactions;" and in 1756 he contributed to the same work an article on certain coralloid bodies occurring in Shropshire. This coming under the notice of Linnæus, he was elected upon his recommendation a member of the royal society of Upsal. In 1761 appeared the first part of his great work on "British Zoology." This treatise, which was translated into Latin and German, embraced nearly every species of the animal kingdom then known to exist in Britain, with the exception of insects. The best edition is that of 1776 (4 vols. 4to.). During the publication of the work, he travelled on the continent (1765), and became acquainted with Buffon, Haller, Trew, Gronovius, Pallas, and other men of science. On his return he began a work on "Indian Zoology," which was speedily discontinued. He made a journey into the northern part of Scotland in 1769, and another in 1772, of both of which he published accounts. In 1771 appeared his "Synopsis of Quadrupeds," which was subsequently enlarged and republished under the title of a "History of Quadrupeds." Shortly afterward he began a work called "The Genera of Birds," which was never completed. His "Arctic Zoology" (3 vols. 4to., 1784–'7) contains descriptions of many species previously unknown, and in its compilation he was largely assisted by foreign naturalists. In 1793 he published an autobiography entitled "The Literary Life of the late Thomas Pennant," stating in the advertisement that his existence as an author ended March 1, 1791. Speedily reviving, however, he published several other works, among which were "Outlines of the Globe," vols. i. and ii., including "Views of Hindostan," forming the first portions of a work designed to embrace an account of every country in the world. Two additional volumes were issued after his decease by his son, completing eastern Asia. Pennant also wrote "A Tour in Wales" (4to., 1778); "A Journey from Chester to London" (1782); an "Account of London" (1790); and the "History of the Parishes of Whiteford and Holywell" (1796). He wrote too much and too rapidly to be accounted an authority of the highest kind, although his attainments, especially in the department of natural history, were of a very respectable order.

PENNANT'S MARTEN. See FISHER.

PENNSYLVANIA, one of the 13 original states of the American Union, included in the middle states, and now the second in wealth and population in the Union. Its geographical position is nearly central as regards the area of the original colonies, a position which is popularly recognized in the customary designation of this as the "keystone state." Pennsylvania was somewhat indefinitely bounded as originally granted by charter; but in the final adjustment of colonial limits it was made a nearly perfect parallelogram W. of the Delaware river, a small addition being made at its point of contact with Lake Erie to give it access to lake navigation and a good harbor. It is bounded N. by Lake Erie and New York, mainly along a right line at lat. 42° 15′ N.; E. by the Delaware river, which separates it from New Jersey along an irregular line between long. 74° and 75° W.; S. by Delaware and Maryland along a right line at lat. 39° 43′ N.; and W. by Virginia and Ohio, along a right line at long. 80° 36′ W.; average length 310 m., width 160 m.; area, about 46,000 sq. m., or 29,440,000 acres. The state is divided into 66 counties, viz.: Adams, Alleghany, Armstrong, Beaver, Bedford, Berks, Blair, Bradford, Bucks, Butler, Cambria, Cameron, Carbon, Centre, Chester, Clarion, Clearfield, Clinton, Columbia, Crawford, Cumberland, Dauphin, Delaware, Elk, Erie, Fayette, Forest, Franklin, Fulton, Greene, Huntingdon, Indiana, Jefferson, Juniata, Lancaster, Lawrence, Lebanon, Lehigh, Luzerne, Lycoming, Mercer, M'Kean, Mifflin, Monroe, Montgomery, Montour, Northampton, Northumberland, Perry, Philadelphia, Pike, Potter, Schuylkill, Snyder, Somerset, Sullivan, Susquehanna, Tioga, Union, Venango, Warren, Washington, Wayne, Westmoreland, Wyoming, York. The chief cities and towns are: Harrisburg, the seat of government; Philadelphia, the commercial centre of the state; Pittsburg, Reading, Lancaster, Pottsville, Easton, Erie, York, Norristown, Allentown, Scranton, Williamsport, Danville, Wilkesbarre, Carlisle, Gettysburg, Columbia, Phœnixville, Chester, West Chester, Lebanon, Chambersburg, Hollidaysburg, Brownsville, Beaver, Meadville, Honesdale, Mauch Chunk, Port Carbon, and Bristol. —The following statement exhibits the decennial progress of population since 1790

Census.	Whites.	Free colored.	Slaves.	Total.	Increase per cent.
1790	424,099	6,537	3,737	434,373	....
1800	586,094	14,564	1,706	602,365	38.7
1810	786,804	22,492	795	810,091	34.5
1820	1,017,094	32,153	211	1,049,458	29.5
1830	1,309,900	37,930	403	1,348,233	28.5
1840	1,676,115	47,854	64	1,724,033	27.9
1850	2,258,160	53,626	....	2,311,786	34.1
1860	....	....	....	2,916,018	26.1

Ratio to the total population of the United States in 1850, 10.03 per cent.; population to the square mile in 1850, 63. The population of 1850 was classified as follows: white males, 1,142,734; white females, 1,115,426; colored males, 25,369; colored females, 28,257. Born in the state, 1,844,672; in other states, 161,129; in England, 38,048; in Ireland, 151,723; in Scotland and Wales, 16,212; in British America, 2,500; in Germany, 78,592; in France, 4,083; in other countries, 7,796; unknown, 3,296. Total of foreign birth, 296,985, or nearly 13 per cent. The leading occupations in 1850 were: agriculture, 207,535; manufactures, 105,883; commerce and trade, 21,309; learned professions, 9,901. Deaths in the year ending June 1, 1850, 28,551, or 1.2 per cent. of the population; paupers, 11,551; deaf and dumb, 1,145; blind, 969; insane, 1,914; idiotic, 1,467.—The surface of Pennsylvania is level in the S. E., hilly and mountainous in the interior, and generally level or arable in the W. The S. E. counties are but little elevated above the sea, but in proceeding westward and northward a series of ridges are met, rising higher and becoming more abrupt to the Blue ridge and the Alleghanies. These ridges and mountains all trend N. E. and S. W., those eastward of the Alleghany range being precipitous, but westward from this range the surface declines toward the Ohio river and Lake Erie in gradual slopes. The passes of this interior range are about 2,000 feet above the sea, the lower valleys of the Ohio where it leaves the state, and the plain bordering Lake Erie, being about 800 and 650 feet respectively. The interior valley through which the Susquehanna river flows is but little elevated above the sea, and it occupies a large area, dividing the mountainous belt. The mountains of the state are part of the great Appalachian chain. At the N. E. they connect with the Shawangunk mountains of New York and the Blue ridge of New Jersey, the last named being continued southwestward through the entire state and into Maryland under the same name. The Blue ridge is about 1,500 feet high. The only considerable mountain S. and E. of this ridge is the South mountain, a broken chain of ridges about 1,000 feet high at the highest portions. Next N. and W. of the Blue ridge a number of sharp irregular mountain ridges succeed, the Tuscarora, Path Valley, Broad Top, Sideling hill, Shade, Black Log, and Tussey's mountain S. W. of the Susquehanna; and Mahanoy, Sharp mountain, Lackawanna, Wyoming, Moosic, Pocono, and Nesquehoning, N. E. of the Susquehanna. Beyond all these is the Alleghany range proper, which extends in a curved line through the entire state, connecting with the chief range of the same name in other states. Its highest ridges are the Eagle, Chestnut, and Laurel ridges, which are 2,500 feet high on an average, with some peaks of 3,000 feet. They pass out of the state at the S. W. into Maryland and Virginia. The ridges E. of the Alleghany range are too abrupt for cultivation, but its W. slope is nearly all arable, even at an elevation of 1,800 or 1,500 feet. The valleys of Pennsylvania correspond to the mountain ridges in the central part of the state. They generally cross the line of the great rivers, conforming to the mountain configuration. Chester valley in the S. E., Wyoming and Lackawanna valleys in the N. E., Juniata and Sinnemahoning in the centre, Cumberland in the S., and Monongahela valley in the S. W., are the principal. Many deep narrow valleys occur in the mountainous region which traverses the state from N. E. to S. W. in a belt 150 m. wide and 250 m. long.—The Delaware river, which forms the E. boundary of the state, has tide water 132 m. from the sea to Trenton, and great depth at Philadelphia, the average depth at the wharf line of that city exceeding 45 feet. It is navigable for the largest ships to Philadelphia, for steamboats of large size to Trenton, and for small steamboats to Easton. It breaks through the Blue ridge at the Delaware Water Gap, above which it is not navigable. The Susquehanna river drains the central part of the state, and runs southward to Chesapeake bay; it is a rapid, broad, and shallow river, not navigable for steamboats in Pennsylvania, but it floats great quantities of timber. Canals along its banks convey coal and produce in great quantities. The Susquehanna has two great branches, the North branch rising in New York, and having an irregular course of 250 m. to Northumberland, the point of junction, and the West branch rising W. of the Alleghanies, through which it breaks eastward, and is 200 m. long. Below Northumberland, 130 m. from the sea, the course of this river is more direct. The Ohio river and its branches drain the W. part of the state; the Alleghany river drains the N. W. part, and has a length of 160 m., running southward to Pittsburg; the Monongahela, rising in Virginia, has a course northward within the state of 70 m. to Pittsburg. Both these last are navigable for steamboats about 60 m. each, and the Ohio, below their point of junction, is a great thoroughfare for steam navigation. The Juniata, a tributary of the Susquehanna from the west, and the Lehigh and Schuylkill, tributaries of the Delaware, are the principal remaining rivers, each having canals and lock navigation. There is no considerable lake within the state, but it borders on Lake Erie for a distance of 45 m., affording access to its navigation and a superior harbor at Erie.—The geological formations of Pennsylvania are limited to a few only of the great divisions of the rocks. These are metamorphic (including the gneissic as well as the altered lower palæozoic groups); the palæozoic series from the Potsdam sandstone to the coal measures; and the middle secondary red sandstone. The tertiary and upper secondary, developed on the E. side of the Delaware, do not extend to the other side of the river. The northern drift formation of sand and gravel, which overspreads all the states to the N., enters Pennsylvania at its N. corner, and is represented by a thin sheet of gravel, which dwindles away within 30 or 40 m. of the New York state line, except where it is traced down the valley of the Delaware at the E. and the branches of the Ohio at the W. Along the middle portion of the N. boundary of the state the height of the table-land appears to have been sufficient to arrest the current by which this formation was deposited, for its bowlders and gravel are rarely detected in this portion of the state. The gneissic rocks, and the middle secondary red sandstone that lies within an elongated basin of the former more ancient group, are limited to the S. E. counties of the state, the gneiss occupying a margin of varying width along the Delaware below Trenton, at Philadelphia reaching up the Schuylkill about 10 m., and giving place on the N. W. to a narrow belt of metamorphic limestones, slates, and quartz rock, which separates it from the red sandstone. This belt contains the quarries of white marble that have supplied with this material the city of Philadelphia and the towns around. To the N. and N. W. of it the gneiss appears again and overspreads the N. part of Chester co., reaching to the red sandstone formation, along the line of which, near Phœnixville, are the mines of lead and copper, of which some account is given in the article LEAD. On the range of the gneiss toward the S. W. is the mine in Lancaster co. which supplies the nickel to the U. S. mint for the new cent, and more of the metal also for exportation. Along the line of the gneiss and sandstone W. of Phœnixville are the Warwick and other mines of magnetic iron ore. South from Philadelphia the gneiss continues round the border of the state, the edge of this formation N. of the Maryland state line coming to a point before reaching the Susquehanna river. In this region, near the Octarara creek, are tracts of serpentine rocks, forming what are called the "serpentine barrens." In these rocks beds of chrome iron ore have been worked to a considerable extent, and at times with great profit, affording large quantities of the ore for the manufacture of chrome paints at Baltimore and for the English market. Trap dikes are of frequent occurrence, not only over the gneiss region, but over all the district of the metamorphic slates, limestones, and quartz rock, and the unaltered lower silurian formations into which these pass. Nearly the whole of Chester and Lancaster cos. are occupied by these groups, and to the N. W. of the red sandstone tracts they are met with again in Berks and Lehigh cos., ranging with the South mountain and coming out on the Delaware at the mouth of the Lehigh, and thence to the bend of the river below Durham. The lower silurian formations contain the great deposits of hematite iron ore, as the Chestnut hill mines near Columbia in Lancaster co., and the numerous beds in Berks and Lehigh cos. which form the chief dependence of the blast furnaces on the Schuylkill and the Lehigh rivers. (See APPALACHIAN MOUNTAINS, HEMATITE, and IRON.) Magnetic iron ores also occur in the same geological position in numerous localities. The Cornwall mine in Lebanon co., situated in the Potsdam sandstone close to the S. line of the red sandstone tract, is one of the most important mines of this ore in the United States.—The red sandstone formation is a continuation of the same group that crosses New Jersey and Maryland. Its N. line, ranging with the Musconetcong creek in New Jersey, crosses the Delaware river below Durham, and extending in a W. direction crosses the Schuylkill 2 m. below Reading and the Susquehanna 5 m. below Harrisburg. It then inclines more to the S. and crosses the S. line of the state near the S. W. corner of Adams co. The S. line of the same belt enters the state opposite Trenton and pursues a general W. course, passing the Schuylkill 2 m. below Norristown, the Susquehanna in the W. corner of Lancaster co., and the state line in Adams co. near the S. E. corner. The tract thus included is occupied almost exclusively by the red sandstones, red shales, and conglomerates of this formation, and by the numerous dikes of trap rock, many of which are of enormous dimensions, and are traced for miles in different directions. It is remarkable that the dip of the sedimentary rocks is not disturbed by these dikes from the uniform inclination of the strata at angles varying from 15° to 20° toward the N., and thence to N. W. The sandstones afford some good building stones, of which there are quarries on the Schuylkill and the Delaware. Next to this belt and the metamorphic rocks, which bound it on the N. and W., lie the lower silurian sandstones and limestones, which are at the base of the long series of palæozoic formations that occupy all the remaining portion of the state. The divisions of this series are given in the article GEOLOGY, vol. viii. p. 157; and they amount in aggregate thickness to over 85,000 feet. The lower members lie along the N. side of the South mountain and the W. side of the continuation of the same range in the S. part of the state, and dipping N. and W. they pass beneath the "auroral" magnesian limestones of the Kittatinny valley. These limestones, corresponding to the Chazy, birdseye, and Black river limestones of New York, fill the whole broad valley between the Kittatinny and Blue mountains on one side and the South mountain on the other. (See APPALACHIAN MOUNTAINS.) Their range is marked by soil of great fertility, and the finest agricultural region of the state is this great limestone valley, occupying the chief portion of Northampton, Lehigh, Berks, Cumberland, and Franklin cos. Beyond this to the N. and W. is a wide belt of country, reaching to the main Alleghany mountains, singularly picturesque, and strongly marked by its peculiar geological and topographical features. Long narrow ridges parallel to each other, after running many miles in straight lines and then curving together, and varied by the occasional termination of one of them upon the plain of the valleys that lie between them, are everywhere encountered over this region of middle Pennsylvania. The rivers and the roads follow the long lines of the valleys, finding a passage across from one to another by the occasional gaps and ends of the ridges. The great pile of the palæozoic formations, raised and crumpled in long folds, the bearing of which is with the mountain ranges, presents its various members in regular succession; and each one of these along the line of its outcrop impresses its peculiar form of outline upon the surface. When the limestone belts, by reason of their enormous thickness or by their changing dips, are spread over a wide area, this is a valley between the steep ridges, in which the sandstones, that have more stoutly resisted the denuding action, form bold cliffs and give a sharp outline to the ridges. As these formations are continually repeated in approaching the main Alleghany mountains, the result is the succession of ridges and valleys, in each of which the geological formations are instantly recognized by the surface contour. The chief minerals of importance in this series of formations below the coal measures are the iron ores, of which mention has been made in the article IRON. In a few districts E. of the Alleghanies the coal measures appear sometimes only over a very limited area upon the summits of the highest ridges, and with no great depth of the formation; and at others forming elongated basins or troughs, as those of the anthracite region of N. E. Pennsylvania, in which the strata curve upward on each side, giving place to the underlying formations outside of the basins. Within each basin these strata present frequent changes of dip, the successive anticlinal and synclinal axes lying nearly on the general range of the basin, and the flexures being often sharp. The character of the formation and the annual product of the coal to the close of the year 1856 are described in the article ANTHRACITE. Since that time the production of the different districts has been as follows, the aggregate, as given in the table, including the production of a few unimportant localities not particularly named. The figures represent tons:

Years.	Schuylkill Region.				[illegible] Anthracite Region.		
	By canal.	By railroad.	Pine Grove.	Little Schuylkill	Shamokin.	Lykens Valley.	Trevorton.
1857	1,375,989	1,472,544	208,500	360,049	150,540	121,650	108,731
1858	1,325,504	1,582,692	233,500	326,796	187,000	137,770	148,696
1859	1,371,738	1,063,150	165,000	362,192	180,000	109,250	124,950
1860	1,266,899	1,678,067	145,636	317,094	211,000	176,250	98,518

Years.	Northern or Wyoming Coal Field.				Lehigh Region.		Aggregate.
	Delaware and Hudson Canal co.	Pennsylvania Coal co.	By canal.	Delaware, Lackawanna, and Wyoming railroad.	By canal.	By railroad.	
1857	480,677	542,575	405,919	490,925	900,314	413,296	6,764,567
1858	348,738	690,868	528,086	690,260	916,508	471,129	7,002,990
1859	590,165	894,285	457,044	820,000	1,450,882	577,683	7,685,500
1860	499,369	881,469	460,943	1,077,500	1,181,022	790,842	8,426,098

The summit of the Alleghanies in Pennsylvania is the E. margin of the great bituminous coal field. The highest points are capped by the conglomerate which underlies the coal formation, or by the lower members of this series, and the strata dipping gently toward the W., the formation gains in thickness in that direction, overspreading nearly the whole western part of the state, except the N. W. corner. No means are afforded of estimating the amount of coal produced, as the mining operations are not concentrated at a few points, but are carried on everywhere, and more for local purposes than for transportation to market over railroads and canals. From Westmoreland co. an amount estimated at 100,000 tons per annum is sent to Philadelphia for manufacturing gas. The subject is further treated in the article COAL. The other useful mineral beds found interstratified with the coal are fire clay, limestone, iron ore, and sandstone. All these occur over the whole range of the formation, the iron ores abounding especially in the lower part of the measures, which brings them to the surface near the margin of the coal field. For the statistics of the production of this metal, see IRON. Salt is obtained by boring through the coal formation of the western portion of the state, and this business is extensively carried on in the valley of the Kiskiminetas. The annual product of salt is estimated at about 1,000,000 bushels. Rock oil or petroleum has recently been obtained in large quantities, associated with the salt in the N. W. part of the state, for an account of which see PETROLEUM. Among the mineral springs those of Bedford are the most celebrated.—The soil of the state is generally rich, that of Lancaster co. on the limestone in the S. E., and of some of the counties bordering the Ohio river and also underlaid with limestone in the W., being particularly noted for productiveness.

In the S. and E. the abundance of lime constitutes good grain soils generally, and there are none of the thin tertiary sands, or of the weak soils lying on primary rocks, which belong to other states of the seaboard. The mountain valleys of the interior generally contain limestone, which secures good soils. In the N. grazing soils preponderate; these are rich on the upper Susquehanna in the N. E., thin and cold on the highlands of the central counties of the N. border, and again very rich and productive in the N. W. The whole W. border of the state is, like the Ohio valley generally, alike adapted to grain and grazing.—The improved lands of the state reported in 1850 numbered 8,628,619 acres in 127,577 farms, or less than one third the sufrace; the opening of new lands in the N. central counties will have increased the proportion to about one third in 1860. The unimproved land held in farms in 1850 was 6,294,728 acres. Extensive wooded tracts well adapted to agriculture yet remain unoccupied in the N. central counties. In 1850 there were produced in the state 15,867,691 bushels of wheat, 19,835,214 of Indian corn, 21,538,156 of oats, 4,805,160 of rye, 2,192,692 of buckwheat, 165,584 of barley, 55,231 of peas and beans, 5,980,732 of Irish potatoes, 52,172 of sweet potatoes, 178,983 of clover and grass seeds, and 41,728 of flax seed; 1,842,790 tons of hay; 912,651 lbs. of tobacco, 4,481,570 of wool, 39,878,418 of butter, 2,505,034 of cheese, 2,326,425 of maple sugar, 839,509 of beeswax and honey, and 530,307 of flax. The value of live stock was $41,500,053; of slaughtered animals, $8,219,848; of market products, $688,714; of orchard fruits, $723,389; and of household manufactures, $749,132. Establishments for manufacture producing $500 or more in value, yearly, were reported in 1850 to the number of 21,605, employing $94,473,810 capital, and producing goods to the value of $155,044,910. The statistics of the leading classes of manufactures were as follows in 1850:

Establishments.	No.	Capital.	Male hands.	Female hands.	Value of products.
Cotton mills.	208	$4,528,925	8,564	4,009	$5,822,262
Woollen " .	880	8,005,064	8,490	2,236	5,821,866
Pig iron furnaces......	180	8,570,425	9,285	9	6,071,518
Cast iron establishm'ts.	820	8,422,924	4,872	1	5,854,881
Wrought iron estab'm'nts	162	7,828,916	6,591	7	9,224,256
Brew'ries and distilleries.	871	1,719,960	1,092	0	6,548,810
Salt works...	47	168,860	219	0	206,796

The production of pig iron was 285,702 tons in 1850, by the U. S. census. The returns of that census were known to be in error at least for Philadelphia, that city producing much more in manufactures, and having a greater number of establishments, than was then reported.—In foreign commerce Pennsylvania holds the fifth place; but it imports through the port of New York, in the name of and for its merchants alone, large amounts of valuable foreign goods, not included in the official figures below. The value of imported goods in the fiscal year ending June 30, 1859, was $14,520,331; of exports for the same year, $5,875,588. For the calendar year 1860 the total imports were $15,190,755, and the exports, $7,843,510. The shipping employed was as follows in 1860: entrances, 449 American vessels, tonnage 134,820, and 147 foreign, tonnage 36,308; total entered, 596 vessels, 171,128 tons; clearances, 356 American vessels, tonnage 105,127, and 131 foreign, tonnage 127,858; total cleared, 487 vessels, 232,985 tons. The total shipping owned in the state in 1859 was, of registered tonnage, 57,859; of enrolled and licensed, 226,884; total, 284,744. The number of arrivals at the port of Philadelphia in 1860 was, of foreign vessels, 582; vessels from domestic ports (including boats and barges), 37,746; total, 38,328. Vessels built in the state in the year ending June 30, 1859, 108, tonnage 14,476.—The internal trade of Pennsylvania is very great over its railroads and canals. The central railroad conducts the largest trade to and from the western states; the Philadelphia, Wilmington, and Baltimore road to and from the south; the Reading and North Pennsylvania roads carry the northward trade, and the New Jersey roads an immense traffic to and from New York. An extensive canal system also exists, but it has been sold by the state in divisions to various private companies, and is less important now than it was a few years since. The Pennsylvania central railroad is 356 m. long from Philadelphia to Pittsburg, and has a double track for all but 68 m. Beyond Pittsburg, the Pittsburg, Fort Wayne, and Chicago railroad has a length of 50 m. within the state, and the Pittsburg and Steubenville road 30 m. This central line has now 282 m. of canal, purchased from the state, and worked in connection with the railroad by the same company. The Reading railroad has a length of 52 m. from Philadelphia to Reading, from which point it connects with Harrisburg over the Lebanon valley road; with various points of the coal-mining region; with Catawissa, Williamsport, and Elmira, N. Y. The Sunbury and Erie road has a total length of 289 m., of which 80 m. are yet unfinished. The total length of railroads in operation in the state in 1860 was 2,943 m.; their total cost was $151,530,000. The total length of canals in use in 1860 was 1,030 m. On the Lehigh, Schuylkill, Delaware, Susquehanna, and Monongahela rivers the canals and slack water navigations convey immense quantities of coal to market, and the railroads in and leading from the coal fields also find their chief freight in coal, both carrying, in the year 1860, over 9,000,000 tons. Great quantities of lumber and timber are transported on the Susquehanna and Alleghany rivers out of the state to market. Western produce is carried most largely by the central railroad; next by the chain of roads in the north, and by the road from Baltimore at the south.—On Nov. 1, 1860, there were 89 banks, the condition of which was as follows:

capital, $25,808,553; loans and discounts, $65,-397,472; stocks, $2,877,774; real estate, $1,-766,255; other investments, $1,045,641; due by other banks, $4,549,999; cash items, $4,-012,286; specie, $7,818,769; circulation, $13,-830,000; deposits, $27,032,104; due to other banks, $4,118,925; other liabilities, $1,072,-150. A free banking law was passed in March, 1860. No banks are permitted to issue notes below the denomination of $5. There are also 30 or 40 savings institutions, proper to be ranked as savings banks, not included in the above, and not reporting to the bank department of the state, 16 of which are in Philadelphia.—The government of Pennsylvania is under a state constitution adopted in 1790, previous to which the chief executive office was the president of the executive council. This constitution was amended in 1838, 1850, and 1857. The legislative body consists of a house of representatives of 100 members, chosen annually from single districts; and a senate of not less than one fourth or more than one third this number—now 33 members—elected for 3 years. The executive department consists of a governor elected by the people for 3 years, whose salary is $4,000; an auditor-general and a surveyor-general elected by the people; a secretary of the commonwealth, appointed by the governor; a state treasurer elected by the legislature, &c. The legislature meets and the executive departments report to it on the first Tuesday of January of each year. The judicial department consists of a supreme court of 5 judges elected by the people for terms of 15 years, one in every period of 3 years. These also have jurisdiction in courts of oyer and terminer. There are 25 courts of common pleas for as many districts, in each of which a president judge is elected by the people for 10 years; and one or more associate judges are elected for each county. The judges of common pleas in each county are also justices of oyer and terminer, but may not hold such courts when a judge of the supreme court is in the county. There is a district court for Philadelphia city and county, and one for Allegheny county, which includes Pittsburg. The judges of the supreme court and the president judges of common pleas receive $1,600 annual salary; the judges of the city districts receive $2,000 to $5,000 salary.—The value of real and personal property in Pennsylvania was assessed in 1858 at $559,049,667, on which a tax was paid in 1860 of $1,479,577; the number of persons taxed was 640,176. The public debt of the state, Dec. 1, 1860, was $37,964,609. The total revenues received into the treasury for 1860 were $3,479,257, and the total expenditures of the same year $3,687,147, including a payment of $591,758 on the public debt. The principal revenues of the state are derived from a tax of 2½ mills on $1 of all real and personal estate; from a tax on banks and corporations, yielding in 1860 $302,000; from various business licenses, $370,750; from tax on loans, $1[illegible]; from interest on loans by the state, $414,[illegible]; from collateral inheritance tax, $146,047; from sale of public works, $100,000, &c. The chief expenditures in 1860 were: for interest and principal of the public debt, $2,614,080; for expenses of the state government, $401,863; for common schools, $282,952; for charitable institutions, $128,320; for houses of refuge and penitentiaries, $38,449; for abatement of the state tax, $52,265. Balance in the state treasury, Dec. 1, 1860, $722,405.—The charitable and penal or reformatory institutions of the state are to some extent blended, but a number of very important charitable institutions exist, founded and supported wholly by private contributions. There are two great penitentiaries, one at Pittsburg and one at Philadelphia, both originally organized on the system of solitary confinement, and still so maintained. This has been called the Pennsylvania system, which is asserted to work well, though when tried elsewhere it has in some cases been reported as too severe. The constant visits and efforts of the prison discipline society have here a favorable influence on convicts, relieving the severity of what would otherwise be absolutely solitary confinement. The eastern penitentiary, on Jan. 1, 1861, contained 464 convicts, and the western about 400. A house of refuge for juvenile delinquents exists in Philadelphia and one in Pittsburg, supported by the state, and one for adults has been authorized to be built at Philadelphia. There is a state lunatic asylum at Harrisburg, which has 200 patients; a hospital for the insane at Pittsburg; an asylum for the deaf and dumb, which has 215 patients; and an institution for the blind with 165 patients. These are all supported in greater part by the state, and the last two are situated in Philadelphia. There is also an institution supported in part by the state for the training of feeble-minded children, near Philadelphia. Among the many charitable institutions supported by private endowment, the Pennsylvania hospital, and its insane department, both in Philadelphia, and the Girard college for orphans, are the most conspicuous. (See PHILADELPHIA.)—A liberal common school system was adopted in 1838, under which the counties had power to establish free or partially free schools as each should choose, support being given by the state only to those counties which should tax themselves for the support of schools. The greater number of counties at once accepted the act, and organized schools under it; but a few neglecting to do so, the legislature in 1854 directed the maintenance of free schools in the entire state, and the assessment of the requisite tax in the counties, $200,000 or more being annually appropriated by the state from its general revenues. This system is now in successful operation, and very effectively directed by state and county superintendents, who report annually. The common schools in 1860 numbered 11,677, educasive of Philadelphia, in which there were 335 public schools. The number of pupils who attended public schools in the whole state was 647,414. The number of teachers was 14,065, of whom, out of Philadephia, 8,171 were male and 4,832 female teachers. The cost of the whole system for 1860 was $2,619,377, of which sum $280,000 was appropriated from the state treasury, and the remainder assessed by tax in the country districts and cities. The average term of all schools out of Philadelphia was 5 months and 5¼ days, and the average cost for each pupil 56 cts. In Philadelphia the schools are wholly free; and in the country the state and county appropriations in most cases render tuition free. The state and county superintendence cost $45,000; and two state normal schools are supported at a cost of $30,000. A system of academies was organized and endowed some years since, one in each county; but many of these, with their endowment, have been merged in colleges or common schools. Only 20, with 1,343 students, were in operation in 1860. There are 26 colleges, but one of which receives aid from the state; of these, 9 are literary, 7 theological, 8 medical, 1 law, and 1 agricultural. The aggregate number of students is about 2,500, of whom 1,250 attend the medical schools. These last are the most celebrated and successful of their class in the country. The medical department of Pennsylvania university was founded in 1765, and Jefferson medical college in 1824. Of the adult population in 1850, 51,283 of native birth and 24,989 of foreign birth could not read and write.—The number of churches in the state reported in the census of 1850 was 3,566, of capacity to accommodate 1,574,873 persons, and valued, with other church property, at $11,586,115. The number of Methodist churches was 889, Presbyterian 775, Lutheran 498, Baptist 320, German Reformed 209, Friends' 142, Episcopal 136, Roman Catholic 139, Mennonite 92, and Moravian 84.—The number of libraries in the state in 1850 was 393, containing altogether 363,000 volumes. Of these, 90 were public libraries, with 184,666 volumes; 30 school libraries, with 17,161; 226 Sunday school, with 58,071; 21 college, with 77,050; and 26 church libraries, with 26,452. A large increase in the number both of libraries and volumes has occurred since 1850. In the same year there were 310 newspapers and periodicals, of which 71 were literary and miscellaneous, 198 political, 28 religious, and 12 neutral and independent; 24 were issued daily, 261 weekly, 19 semi-monthly, &c. The circulation of numbers, as issued daily, weekly, and otherwise, was 983,218; and the total number of copies annually printed was 84,898,672. The present actual number of daily journals is 27, and the issue of other papers and periodicals has greatly increased.—The Delaware bay and river received its first civilized colony from Sweden. An extensive scheme of colonization for the new world was projected in Sweden under very high auspices, nearly at the same time that the New England colonies were sent out, and a few years previous to Calvert's colonization of Maryland. In 1627 a well provided body of Swedes and Finns settled on both shores of the Delaware, making their way nearly to the site of Philadelphia. They made little progress in the occupation of the country, were compelled to submit to the then flourishing Dutch rule at New Amsterdam in 1655, and passed without resistance under the English jurisdiction generally established in 1664. In 1681 the territory west of the Delaware was granted to William Penn, who colonized it, and founded Philadelphia in 1682. Under the charter granted to Penn by Charles II. the present area of the state of Delaware was included, and called the lower counties; and they continued under the same proprietary until 1699, when a separate legislature was granted them, but not a distinct government. The two colonies were so connected until the revolution of 1776. The grant to Penn was for territory really covered by the vague grants made to the New England colonies, Virginia, and Maryland; and though the lines on the E., N., and W. were adjusted without difficulty, the boundary between Pennsylvania and Maryland was long a subject of contest by the heirs of the original proprietors, and it was finally settled by the survey of Mason and Dixon, begun in 1763 and completed in 1767. (See MASON AND DIXON'S LINE.) The original Swedish colony was unusually free from trouble with the Indians, and after Penn's colony was founded a remarkable and most successful peaceful policy was inaugurated with the savage tribes in contact with the colony. Impressing them by acts of justice, firmness, and good faith, Penn secured for his successors uninterrupted peace with the Indians until the opening of the revolutionary war. The disastrous expedition of Braddock and the massacre of Wyoming proved, however, that the character of the Indians was the same here as elsewhere. The settlers of the lower counties were, after the Swedes, originally mainly Friends. Their high character and steady energy made this one of the most flourishing colonial establishments, if not, all things considered, quite the most successful. It became the seat of learning, wealth, and refinement long before the revolution, and continued to enjoy a high position throughout the changes incident to the founding of a new government. Its central position drew to it the sessions of the continental congress, and it was the seat of the general government then formed until 1800. Independence was proclaimed here, and the whole colony took a decided, yet not a violent or embittered part in the war of the revolution; Brandywine, Germantown, Valley Forge, and other points becoming sacred to the whole nation for memorable events. The first large accession to the population, next to the Friends, was from a German immigration begun about 1750, which prised several counties adjacent to Philadelphia, and has given prominence to that nationality in all the subsequent history of the state. There was a considerable immigration of Scotch [illegible], but coming immediately from the N. of Ireland, which was diffused largely over all the state. Since these events the usual interchange [illegible] constantly going on in American [illegible] has occurred, and Pennsylvania has contributed very largely to the settlement of all the new western states.

PENNY, an English coin of the value of $\frac{1}{12}$ of a shilling. The Saxons introduced it and made it of silver, weighing about 22½ grains, or $\frac{1}{240}$ of the pound. It was divided by a deeply indented cross into 4 quarters, which might be separated by breaking them apart; hence the introduction of the fractional terms halfpenny and farthings (four things). Its weight was reduced by Edward I. to $\frac{1}{20}$ of an ounce, and in the reign of Elizabeth its value was fixed at that of $\frac{1}{62}$ of an ounce, which it still retains. It has long been coined in copper; but on account of the inconvenient size of the copper pennies, a new bronze coinage has been determined on in England, and is now [illegible] executing at Birmingham.

PENNYROYAL (*mentha pulegium*, Linn.), a European species of mint, of smaller size than any of the other species, and of which the entire plant except the root is considered medicinal. Its stems are prostrate; its leaves elliptical, obtuse, nearly entire; its flowers borne in rotating verticillate, sessile spikes from the axils of the leaves; calyx smooth at base and closed by a ring of hairs when in fruit; corolla purple. The plant smells like spearmint, but less fragrant, and has a bitterish and aromatic taste; it yields a very volatile essential oil, which rises at distillation in water. It had much repute at one time as an emmenagogue, expectorant, and diaphoretic, acting on the uterus, and [illegible] hysteria, whooping cough, and asthma. It occurs in moist places, heaths, and [illegible].—The American pennyroyal (*hedeoma pulegioides*, Persoon) is a warm-tasted, aromatic little herb, with nearly the same flavor and odor as the true pennyroyal. It grows in [illegible] barren woods, or on sunny hills among stones, and in fields. Its stem is 6 to 12 inches [illegible], erect, branching, and hairy; its leaves [illegible], oblong-ovate, obscurely serrate; its [illegible] few-flowered; corolla bluish pubescent, [illegible] much longer than the calyx; fertile stamens [illegible], the other 2 reduced to abortive filaments. [illegible] popular medicine it is held in much esteem [illegible] account of its diaphoretic and carminative [illegible].

PENNYWEIGHT, a weight of 24 grains, which was that of the silver penny in the time of Edward I. This has ever since continued one of the units of troy weight, being equal to $\frac{1}{20}$ of the ounce troy.

PENOBSCOT, a central co. of Me., intersected by the Penobscot river; area, 2,760 sq. m.; pop. in 1860, 72,731. It has a diversified surface and a generally fertile soil. Formerly it comprised a very large territory, which has been gradually cut up to form other counties, and its outlines are very eccentric, being composed of 3 parallelograms irregularly disposed. The productions in 1850 were [illegible] bushels of Indian corn, [illegible] of oats, [illegible] of potatoes, [illegible] of wheat, [illegible] tons of hay, [illegible] lbs. of wool, and [illegible] of butter. There were 7 grist, 2 paper, and 100 saw mills, 2 founderies, 12 tanneries, 1 ship yard, 6 newspaper offices, 65 churches, and [illegible] pupils attending public schools. Capital, Bangor.

PENOBSCOT, the principal river of Maine, formed by the junction, near the centre of the state, in the E. part of Penobscot co., of two chief branches. The W. and larger rises near the Canada border, flows N. E. to Chesuncook lake, from the S. end of which it issues, and after a S. E. course of about 30 m. enters a group of ponds or lakes, Pemadumcook, Millinoket, Twin lakes, and others, issuing from them in two channels, which unite after a short distance. The E. branch, also called Seboois river, proceeds from a number of small lakes in the N. part of Penobscot co., and has a nearly S. direction. The main stream pursues a course a little W. of S., receiving among its most important affluents the Piscataquis on the W. and the Mattawamkeag and Passadumkeag on the E., and falls into Penobscot bay. Its total length, from the source of the W. branch, is about 275 m., and from the junction about 135 m. The principal towns on its banks are Castine, Bucksport, and Orrington on the E., and Belfast, Prospect, Frankfort, Hampden, and Bangor on the W., to the last of which, about 50 m. from its mouth, it is navigable for vessels of large size. Along its course it has numerous falls, affording valuable water power. At Bangor there is a tide of about 20 feet produced by the peculiar wedge-like shape of the lower part of the river.

PENOBSCOT BAY, a body of water on the S. coast of Maine, into which flows the Penobscot river. It is about 30 m. in length, and contains a number of small islands.

PENSACOLA, a city and the principal seaport of West Florida, capital of Escambia co., situated on the N. W. side of the bay of the same name, about 10 m. from its mouth, in lat. 30° 24′ N., long. 87° 10′ W.; pop. about 4,000. The country immediately around Pensacola is barren and sandy, but little cultivated, and covered for the most part with pines. The town itself, although a place of considerable political and commercial importance during the Spanish and English occupation, had until within a year or two past presented rather a decayed appearance, the houses being generally old-fashioned Spanish structures, the streets unpaved, many of them with only wooden sidewalks, and but little appearance of business activity to be observed. Of late there has been a large accession both to its trade and population, in consequence of the approach to completion of the Alabama and Florida railroad, connecting it with Montgomery; and it now bids fair to become one of the most important points in the gulf of Mexico. It has a very admirable harbor, admitting vessels of a draught of 21 feet, and affording almost unlimited accommodation. The principal public buildings are a custom house, Roman Catholic, Episcopalian, Presbyterian, Methodist, and Baptist churches, and an academy. A tri-weekly and two daily newspapers are published. The remains of the old Spanish forts, San Miguel and San Bernard, may be seen in the rear of the city. The city is supplied with water of excellent quality from a number of springs. The climate is exceedingly healthful, except for occasional and rare visitations of yellow fever. The creole element predominates in the resident population, a corrupt *patois* of the French language is extensively spoken, and many of the usages and customs prevailing are quaint and primitive.—There is some uncertainty with regard to the original settlement of Pensacola. It is believed that a few French colonists established themselves here about the year 1696. There is no doubt, however, that the place was in the possession of the Spaniards in 1699, about which time a colony of 300 emigrated thither from Vera Cruz. Their possession was for many years disputed by the French, and in 1719 the place was attacked and taken possession of by Bienville, who held it until 1723, when it was restored to the Spaniards. In 1763 Pensacola, with the rest of Florida, passed into the occupancy of the British. It was again besieged and taken by the Spanish general Galvez in 1781; and in 1783 the whole province was retroceded to Spain. In Nov. 1814, the British forces, which had been permitted by the Spanish authorities to establish themselves at Pensacola, were driven out by Gen. Jackson, who assaulted and took the city and adjacent forts. In May, 1818, Gen. Jackson again took possession of Pensacola, and obliged Fort Barrancas, to which the Spanish governor had retired, to capitulate. This movement was made in consequence of the incursions of hostile Indians from Florida into United States territory, and the inability or unwillingness of the Spanish authorities to suppress them. By a treaty concluded Oct. 24, 1820, and ratified March 22, 1821, the whole province was ceded to the United States. On Jan. 12, 1861, immediately after Florida had declared its secession from the Union, a body of about 500 troops, volunteers from Alabama and Florida, commanded by Col. W. H. Chase, took possession of the navy yard, Forts Barrancas and McRea, the naval hospital, and military barracks, all near the entrance of the harbor. Lieut. Slemmer, of the U. S. army, had two days previously evacuated Fort Barrancas and transferred his command to Fort Pickens, immediately opposite, on Santa Rosa island. The relative position of both sides continued the same until the middle of April, when Fort Pickens was reinforced by about 1,000 U. S. troops under command of Lieut. Col. H. Brown. Col. Chase had previously been superseded by Gen. Bragg, who now (May 15, 1861) invests the fort with from 7,000 to 10,000 men.

PENSACOLA BAY, an arm of the gulf of Mexico, in the western part of Florida, extending inland about 25 or 30 m. in a N. E. direction. At a little more than half this distance from the sea, it separates itself into two divisions, Escambia bay on the W. and on the E. the bay of Santa Maria de Galvez, East bay, or Black Water bay, as it is variously designated. The former receives the waters of the Escambia river; the latter, those of the Black Water and Yellow Water. The entrance of the bay, between Santa Rosa island on the E. and the mainland on the W., is little more than 1 m. wide, but within it expands into a capacious harbor, from 4 to 10 m. in width, and entirely landlocked. There is a depth of about 22 feet of water on the bar. The entrance of Pensacola bay is defended by Fort Pickens on the E., situated on the extreme point of the long, narrow island of Santa Rosa, and Fort McRea on the W., situated on the mainland. About 1½ m. to the N. and immediately in front of the entrance (the W. shore making an abrupt turn to the E.), stands Fort San Carlos de Barrancas. Near this fort are the lighthouse, extensive barracks, and the naval hospital. About a mile above the hospital is the navy yard, situated on Tartar point, where the shore again bends to the N. The villages of Warrington and Woolsey lie immediately adjacent to the wall of the navy yard. Six miles above is the town of Pensacola. At the mouth of Blackwater river is the village of Bagdad, where there are extensive saw mills, sash manufactories, &c. Milton, a thriving village of about 1,200 inhabitants, is 3 m. above. There is a large lumber trade on the shores of Pensacola bay and its tributaries.

PENSIONARY, GRAND, an officer of the Dutch republic, who bore the title also of advocate-general, and was prime minister of the states or legislative body of the province of Holland. He was called grand pensionary from the pension or salary attached to his office. In the assembly of the states he initiated bills, drew up reports, and collected the votes. He also conducted the diplomatic correspondence of the province, received ambassadors, and superintended the finances. He permanently represented the province in the states of the United Provinces, and had great influence not only in the province of Holland, but in the whole republic. The term of his office was 5 years with privilege of reëlection. The most distinguished of the grand pensionaries were John De Witt, killed in 1672, Heinsius, who was in office from 1689 to 1720, and Schimmelpenninck, who was grand pensionary of the Batavian republic from 1798 to 1806, when the office was abolished.

PENTAMETER (Gr. *πέντε*, five, and *μέτρον*, measure), a verse consisting of 5 feet, of which the 1st and 2d are either dactyls or spondees, the 3d always a spondee, and the 4th and 5th anapæsts. Elegiac verses consist of hexameters and pentameters used alternately.

PENTATEUCH (Gr. *πέντε*, five, and *τεῦχος*, book), the 5 books of Moses, being the first 5 books of the Old Testament, viz.: Genesis, Exodus, Leviticus, Numbers, and Deuteronomy. (See Bible, and Hebrews.)

PENTECOST (Gr. *πεντηκοστή*, fiftieth), one of the 3 principal festivals of the Jews, so called in Greek and modern languages because it was celebrated on the 50th day after the feast of the passover, but originally called the "*feast of weeks*" (Heb. *hag hashabuoth*; in the book of Tobit, *ἁγία ἑπτὰ ἑβδομάδων*, the feast of 7 weeks), because it was celebrated 7 weeks after the 16th day of the 1st month of the Mosaic calendar (Nisan). It was and is still observed by the Jews (now generally also on the day following the 50th) as a day of public rejoicing, and also in commemoration of the revelation of the law on Sinai, which happened on the same day.—The day is also kept as a high festival in the Christian church to commemorate the descent of the Holy Ghost upon the apostles, 10 days after Christ's ascension and the commencement of the preaching of the gospel to the gentiles. The apostles, the women, and others, to the number in all of about 120, being gathered together at Jerusalem on the day of Pentecost, "suddenly there came a sound from heaven as of a rushing mighty wind, and it filled all the house where they were sitting. And there appeared unto them cloven tongues like as of fire, and it sat upon each of them. And they were all filled with the Holy Ghost, and began to speak with other tongues as the Spirit gave them utterance. . . . . Now when this was noised abroad, the multitude came together, and were confounded, because that every man heard them speak in his own language." (Acts ii. 2-6.) It is further related that Peter thereupon preached to them, and about 3,000 souls were converted. The precise nature of the gift of tongues, as the power then conferred by the Holy Ghost is generally called, is very variously explained by commentators. Some believe that the apostles were miraculously enabled to speak all languages without having learned them; others suppose the speaking with tongues to have been merely a convulsive sort of utterance followed by intelligible and inspired words. Other critics hold that the speakers used either their own native languages, or an ecstatic tongue which by a miracle sounded to each hearer as if it were his own dialect. A synopsis of the different opinions is given by De Wette. The festival of Pentecost was in the early ages one of the favorite seasons for administering baptism; and as those who received it were clothed in white to symbolize the spiritual purity which baptism confers, the day acquired the name of Whitsunday or Whitsuntide.

PENZA, a central government of European Russia, situated between lat. 52° and 55° N. and long. 42° and 47° E., and bounded N. by Nijni Novgorod, E. by Simbirsk, S. by Saratov, and W. by Tambov; area, 14,840 sq. m.; pop. in 1856, 1,125,967. The surface is level. There are 6 small lakes, and several streams; but the only rivers of any importance are the Sura and the Moksha, both tributaries of the Volga. Valuable iron mines are worked near Troitsk, millstones are extensively quarried, and large quantities of sulphur are found. The cold in winter is very severe, but the summer is mild, and the climate generally healthy. More than half the surface is arable or meadow land, and there are extensive forests. Great attention is paid to raising horses, horned cattle, sheep, pigs, and bees. There are iron works, glass works, tanneries, &c.—Penza, the capital, is situated at the junction of the rivers Penza and Sura, 465 m. S. E. from Moscow; pop. about 12,000. It stands on an eminence, and is built principally of wood. There are manufactories of woollen fabrics, linen, leather, soap, and silk. An annual fair is held, which lasts from June 25 to July 4.

PENZANCE, a seaport and the most westerly town of England, on Mount's bay, Cornwall, 24 m. S. W. of Truro and 9 m. E. N. E. of Land's End; pop. in 1861, 9,214. The situation of the town is exceedingly picturesque, standing on a beautiful shore finely curved, and surrounded by rocky eminences. It has several churches and public buildings, the hall and museum of the Cornwall geological society, and a pier of considerable length with a lighthouse at its extremity. Tin and copper, which abound in the neighborhood, are exported in large quantities, as well as china clay and pilchards. The climate is remarkably mild, and numerous invalids resort thither. Sir Humphry Davy was a native of Penzance.

PEON, a Spanish word signifying a day laborer. In Spanish America it is applied especially to Indian laborers. By the civil law under the Spanish colonial system, and by special statute in some countries, as for instance by the law regulating contracts between masters and servants in New Mexico, peons are compelled to work for their employers, provided they are in debt to the latter, until the debt is paid. They receive wages, amounting in New Mexico to $5 a month. It is alleged that many proprietors, by enticing the peons in their employment into needless expenditures, and by selling them goods and advancing them money, contrive to keep them hopelessly in debt and in a consequent state of bondage. The creditor, however, has no power over the wife and children of the peon, nor can the latter be sold like a slave.

PEORIA, a central co. of Ill., bounded S. E. by the Illinois river and Peoria lake, and drained by Spoon river, Kickapoo, Elbow, and

Copperas creeks; area, 650 sq. m.; pop. in 1850, 17,547; in 1860, 36,945. It has a gently undulating surface and very fertile soil. The productions in 1850 were 1,013,289 bushels of Indian corn, 185,157 of wheat, 138,718 of oats, 12,553 tons of hay, and 40,225 lbs. of wool. In 1860 there were 10 grist mills, 15 saw mills, 3 tanneries, 6 newspaper offices, 72 churches, and 7,941 pupils attending public schools.—PEORIA, the capital, is situated on the W. bank of the Illinois river, here crossed by 2 bridges, each 2,500 feet long, at the outlet of Peoria lake, 70 m. N. from Springfield, and 160 m. by railroad S. W. from Chicago; pop. in 1860, 14,762. It has regular river communication by steamboat with St. Louis, and is connected with Chicago by the Illinois and Michigan canal. The Peoria and Bureau Valley, the Logansport and Peoria, and the Peoria, Oquawka, and Burlington railroads, which concentrate in the city, unite with the principal railroads of the state. It is a city and port of entry, well built, regularly laid out, with wide pleasant streets lighted with gas, and contains, beside the county buildings, several educational institutions, and 24 churches. The products of manufacture in 1860 amounted to $6,717,000. The neighboring bluffs contain inexhaustible beds of coal, and excellent timber also abounds in the vicinity, giving rise to a very extensive trade.

PEPIN OF HÉRISTAL, duke of the Franks, born about the middle of the 7th century, died in 714. He was the grandson of Pepin of Landen and the founder of the Carlovingian family. Inheriting part of the influence of his ancestors, who held the highest rank among the *leudes* or lords of Austrasia, Pepin, in concert with his cousin Martin, the mayor of the palace, led the rebellion against King Dagobert II., who was murdered in 679. The two chiefs then received the title of "dukes of the Franks," and the kingly title in Austrasia was abolished. They attempted to subdue Neustria, which was then ruled by the mayor Ebroin, but were defeated at Leucofao near Laon in 680, when Martin was killed and Pepin remained the only chief of the Austrasians. Occasional hostilities took place during the following years, without any marked success; but Pepin did not give up his ambitious designs, and in 687, having routed the Germans, he was enabled to invade Neustria at the head of a formidable army. The contest ended in the battle of Testry, when Roman France, as northern Gaul was called, succumbed to Teutonic France; and thenceforth the duke was the acknowledged ruler of the whole Frankish empire. He nevertheless permitted Merovingian princes to continue upon the throne; but Thierry III., Clovis III., Childebert III., and Dagobert III. were mere phantoms whom he kept under guard in some villa, bringing them forth but once a year in the national meeting of May, while he wielded unlimited authority, controlling the aristocracy of the chiefs as he did royalty. From 687 to 712 he was engaged in wars against the hostile tribes on the banks of the Rhine, and especially the Frisians and the Alemanni. After repeated defeats, both were subdued. But the latter days of Pepin were troubled by the rivalry between his legitimate wife Plectruda and his mistress Alpaida, the mother of Charles Martel. His own son Grimoald was murdered; and he bequeathed to his grandson under the regency of his widow a power which was soon seized upon by his natural son, whom he had imprisoned.

PEPIN THE SHORT (*le Bref*), king of the Franks, the first of the Carlovingian dynasty, born about 715, died in 768. On the death of his father Charles Martel in 741, he received as his share of the Frankish empire Neustria, Burgundy, and Provence, while his elder brother Carloman had Austrasia and the countries on the right bank of the Rhine. To strengthen his power, he placed on the throne a Merovingian prince, Childeric III., and contented himself with the title of mayor of the palace. In concert with Carloman, he forced the Bavarians, the Alemanni, and the Aquitanians into submission; but Carloman having in 747 retired to a convent, Pepin, setting the just claims of his nephews aside, made himself the ruler of the whole Frankish dominions. He now thought the time had come to add the title of king to his authority; in consequence of which, availing himself of a favorable decision of Pope Zachary and the consent of the lords, he confined Childeric III. in the monastery of Sithin, near St. Omer, and was solemnly crowned and anointed by St. Boniface at Soissons in 752. In the same year he received the submission of Septimania, which for several years had been held by the Saracens of Spain. In 753 he forced the Saxons to recognize his supremacy by paying a tribute of 300 horses and taking an oath to respect the Christian missionaries travelling among them. Pope Stephen III. now visited France to solicit assistance against the persecutions of Astolphus, king of the Lombards. Pepin received the pontiff with great honor, had the ceremony of coronation performed again by him, and started for Italy at the head of his army. He crossed the Alps and besieged Astolphus in Pavia, who sued for peace and assented to the terms dictated by his conqueror; but Pepin had scarcely left Italy, when Astolphus broke the treaty and threatened the city of Rome. Pepin hastened to the rescue (755), conquered the exarchate of Ravenna, and gave it, with the Pentapolis, to the pope, thus founding the temporal sovereignty of the holy see. In 759 he invaded Aquitania, which, under the heroic Waifar, had asserted its independence. A dreadful war of 8 years was waged, and the king of the Franks could only secure his conquest of that province by the assassination of his rival (768). Pepin died a few days after his return from his last expedition thither, leaving his kingdom to his two sons, Carloman and Carl, the latter of whom was afterward known as Charlemagne.

Notwithstanding his shortness of stature, from which his surname was derived, Pepin was noted for extraordinary physical strength; and this, with courage and activity, secured his influence over the turbulent chieftains of Teutonic France.

PEPIN I., king of Aquitania, born about 802, died in 838. The second son of Louis le Débonnaire by his first wife, he received from him in 817 the kingdom of Aquitania, while his youngest brother Louis had Bavaria, and the eldest, Lothaire, was associated in the government of the empire. In 829, when the emperor wished to change this arrangement in order to provide for Charles, who had been born to him by his second wife, Judith of Bavaria, Pepin joined his brothers in a rebellion against their father, whom they confined in a monastery; but soon becoming dissatisfied with the overbearing manner of Lothaire, who had seized upon the imperial authority, Pepin participated in the national assembly held in 830 at Nimeguen, which restored Louis to his throne. His father now designing to take Aquitania from him, he, in concert with his brothers, flew to arms again in 833; and the three princes marched their troops to Alsace, met the emperor at a place afterward known as Lügenfeld, took him prisoner by means of the treachery of his own troops, conveyed him to Compiègne, and forced him to do solemn penance. But at the end of a few months Pepin and Louis of Bavaria, disgusted once more with their older brother's behavior, released their father from his captivity and again acknowledged his supremacy (834). Pepin was addicted to intemperance.—PEPIN II., his eldest son, bereft of his inheritance, which was granted to Charles the Bald, the youngest son of Louis le Débonnaire, was nevertheless acknowledged as king by the Aquitanians. In 840 he joined his uncle Lothaire in his contest against Charles the Bald and Louis the German, was defeated with him at Fontenay in 841, and once more, by the treaty of Verdun in 843, deprived of his kingdom. He still however held his ground, forced Count William of Toulouse into submission, routed the army of Charles the Bald near Angoulême in 844, and finally in 845 obliged his uncle to grant him the best part of Aquitania as a fief. But his popularity among the Aquitanians vanished when he allied himself with the Northmen. Abandoned both by his subjects and his allies, he took refuge in Gascony, but was betrayed into the hands of Charles the Bald by the Gascon chief Sancho in 852. Imprisoned in a monastery, he escaped in 854, induced a number of Aquitanians to rise in his behalf, again procured the assistance of the Northmen, and in 857 obliged Charles to grant him lands. But in a last attempt to take Toulouse at the head of the Northmen in 864, he fell into an ambush, was sent to Pistes, where he was sentenced to death by the lords of the kingdom, and was imprisoned by his uncle at Senlis, where he died soon after. On account of his alliance with the Northmen, he was styled "the Apostate."

PEPPER, a name applied to a number of pungent-fruited plants belonging to distinct orders. The black pepper (*piper nigrum*, Linn.) is the berry of a climbing vine of the East Indies, very extensively cultivated there. It is the type of the pepperworts (*piperaceæ*, Lindley), which comprise in their several species shrubs and herbs with articulated stems, opposite verticillate leaves, which are sometimes alternate in consequence of the abortion of one of the pairs; stipules none, or in pairs or single, and opposite to the leaf; flowers usually sessile, in spikes either terminal or axillary, naked, having a bract on the outside; the stamens 2 or more, arranged on one side; anthers with 1 or 2 cells; stigmas 3; ovary simple, 1-celled; fruit somewhat fleshy, indehiscent, 1-seeded. Some doubt exists among botanists whether the pepperworts are exogenous or endogenous; the venation of their leaves and the general appearance of the wood favor the former supposition, while observations made by Blume in regard to the spiral vessels seem to indicate that they are endogenous. The black pepper has broad-ovate, acuminate, 7-nerved, coriaceous, smooth leaves, pale beneath and dotted when young; the flowers are situated upon long, pendulous, tapering aments, and succeeded by round fleshy berries. These are gathered after the pepper vine is at least 4 years old, and quickly dried upon mats, when they turn black. In this condition they are termed black pepper, and the white pepper of the shops consists of the same berries freed from the husk or rind by maceration in water. Pepper, though usually employed as a grateful condiment, is likewise prescribed as a medicine in cases of relaxed uvula and paralysis of the tongue, and in the form of an ointment for scald-head. Infused in spirit and water, it has been considered more speedy and milder in its operation as a remedy against the return of a paroxysm of intermitting fever than the cinchona alkalies. Pepper is a dangerous stimulant in excessive doses, being found hurtful to the liver and injurious through its impression on the nervous system. The officinal cubebs (*P. cubeba*, Linn.) and another species (*cubeba canina*, Miquel), both common in Java, are extensively used in medicine. The leaf of the betel, which is chewed with the areca nut, is from the *P. betle* of Miquel. The kava plant is the *macropiper methysticum* (Miquel), whose rootstocks are used by the Society Islanders for purposes of inebriation; its medicinal properties are stimulating, narcotic, sudorific, and aromatic. It has a reputation, as a tincture, against rheumatism. There are many other species in this order which possess useful properties. The African pepper consists of the seeds of the *xylopia aromatica* (Blume), growing in Sierra Leone; and another species of Brazil and Guiana is employed for the same purpose by the negroes of those countries. These plants belong however to the *anonaceæ*. The importations of black pepper into the United States for the year ending June 30, 1859, amounted to 7,091,750 lbs., valued at $401,791, of which $107,413 worth was reëxported.—The peppers of the kitchen garden are the fruits of the capsicums, of the natural order *solanaceæ*. (See Capsicum.)

PEPPERELL, Sir William, an American general, born at Kittery Point, Me., in 1697, died there, July 6, 1759. He was brought up as a merchant. About 1727 he was elected one of his majesty's council for the province of Massachusetts, and he was regularly reëlected for 32 years in succession. Living on an exposed frontier, where the inhabitants were constantly engaged in warfare with the savages, a large portion of his life was spent in the camp. He rose to the highest honors, and when the expedition against Louisburg was undertaken, the governors of New England gave him the command of the troops. Beginning the siege in May, 1745, he soon compelled the city to surrender, and in reward for his services was made a baronet. In 1759 he was appointed lieutenant-general. His grandson was created a baronet in 1774, and embraced the royal cause during the revolutionary war, in consequence of which his estates were confiscated. The life of Gen. Pepperell has been written by Usher Parsons (8vo., Boston, 1855).

PEPPERMINT. See Mint.

PEPSIN. See Chyme.

PEPUSCH, Johann Christoph, a German composer, born in Berlin in 1667, died in London in 1752. For a number of years he held an appointment at the Prussian court as harpsichord teacher, and about 1698 emigrated to England, where he passed the remainder of his life. As a composer he is chiefly known by his adaptations of popular airs for the "Beggar's Opera," for which he also wrote an original overture. He was the author of a "Treatise on Harmony" (1731), highly esteemed as a theoretical work.

PEPYS, Charles Christopher. See Cottenham.

PEPYS, Samuel, an English diarist, born Feb. 23, 1633, died May 26, 1703. He belonged to an ancient family, but his father was a tailor, and his own early life seems to have been passed in humble circumstances. He was educated at St. Paul's school, London, and at Magdalene college, Cambridge, where he held a scholarship, but it does not appear that he took a degree. In 1655 he married a young girl without fortune, and went to live with his cousin, Sir Edward Montagu, afterward first earl of Sandwich, whom he accompanied a few years later on his expedition to the Sound. He was immediately afterward appointed to a small office in the exchequer. On Jan. 1, 1659–'60, he began to keep a short-hand diary, which he continued uninterruptedly until May 31, 1669, when he was compelled by defective eyesight to give it up. Though an ardent roundhead in his youth, he expressed great joy at the restoration of Charles II., and accompanied Montagu in the capacity of secretary to the two generals of the fleet when he brought the king over. In the summer of 1660 he was appointed clerk of the acts of the navy, an office which gave him constant opportunities for intercourse with the duke of York, who held the post of high admiral, and with whom he was soon in great favor. His talents for business were of no common order. During the plague of 1665 he had the whole management of the naval affairs. He was one of the commissioners on the affairs of Tangier in 1662, and became treasurer to the commission in 1665. At the same time he was appointed surveyor-general of the victualling office. When the officers of the navy board were called to the bar of the house of commons in 1668, to answer for the disaster to the British fleet in the Dutch admiral De Ruyter's expedition against Chatham, Pepys was chosen by his colleagues to conduct their defence, which he did in a speech of 3 hours with complete success. His diary contains a curious record of the compliments which were paid him on this occasion: "Mr. Vaughan did protest . . . . that he had sat 26 years in parliament, and never heard such a speech there before; for which the Lord God make me thankful! and that I may make use of it not to pride and vain glory, but that, now I have this esteem, I may do nothing that may lessen it!" Nevertheless, though he was many years in parliament, he made no figure there. Shortly after the close of his diary he travelled on the continent, and collected a variety of information respecting the French and Dutch navies. He was not without his enemies; the earl of Shaftesbury attempted to show that he was "a papist or popishly inclined," with a view to defeat him in a contested election case before a committee of the house of commons, and some years afterward attempted to implicate him in the murder of Sir Edmundbury Godfrey. In 1673 King Charles appointed him secretary for the affairs of the navy—an office which only involved him in fresh difficulties, for during the excitement of the popish plot he was accused with Sir Anthony Deane of sending secret particulars respecting the English navy to the court of France, and of being an enemy to the Protestant religion. After 9 months' imprisonment he was discharged, the complainant, Col. John Scott, a man of bad character, retracting his deposition. Pepys had now lost his office, but in 1680 he attended the king at Newmarket, where he took down in short-hand his majesty's narrative of his escape after the battle of Worcester, which has often been published. In 1683 he accompanied Lord Dartmouth's expedition to Tangier. After his return he was appointed secretary for the affairs of the admiralty, a post which he continued to fill with remarkable ability until the accession of William of Orange, when he retired to private life. He was president of the royal society from 1684 to 1686. In 1690 he was arrested on a charge of being too favorable to the exiled James, but was soon released.—By his will Pepys left to Magdalene college, Cambridge, his valuable collection of prints, books, and manuscripts, now known as the Pepysian library. Among them are manuscripts, naval memoirs, and a collection of English ballads in 5 large folio volumes, from which Bishop Percy partly derived his "Reliques of Ancient English Poetry." His diary, after lying unread for more than a century, was deciphered by a young collegian, Mr. John Smith, and part of it published, with a selection from his private correspondence, by Lord Braybrooke (2 vols. 4to., London, 1825). It has since appeared in several more complete editions, and forms 4 vols. of Bohn's "Historical Library." It is universally regarded as one of the most amusing books of its kind ever printed, and it gives us an insight into the manners and social life of the time of Charles II. which we can obtain by no other means. Pepys published "Memoirs relating to the State of the Royal Navy" (8vo., London, 1690), and a further publication of them is in progress, edited by E. F. Rimbault; and his "Journal of Voyage to and Residence at Tangier" has been published from the MSS. in the Bodleian library (2 vols. 8vo., 1841).

PEPYS, William Haseldine, an English chemist, born in London in 1775, died there, Aug. 17, 1856. Early manifesting a taste for the natural sciences, he became a member of the Askesian society, founded in 1796 for the investigation of philosophical subjects, and contributed a number of papers to its proceedings. Out of this society sprang the London institution for the advancement of literature and the diffusion of useful knowledge, the British mineralogical society, and the geological society of London, in all of which Mr. Pepys took an active part. The progress of chemistry and electro-chemistry was for 50 years materially aided by his skill in the construction of apparatus. A voltaic battery for electro-magnetic experiments devised by him is described in the "Philosophical Transactions" for 1823.

PERA, a suburb of Constantinople. See Constantinople, vol. v. p. 687.

PERAMELES, a family of small marsupial mammals, popularly called bandicoots. The dentition is: incisors $\frac{10}{6}$, canines $\frac{1-1}{1-1}$, premolars $\frac{3-3}{3-3}$, and true molars $\frac{4-4}{4-4}$; the teeth are rooted, the premolars compressed and pointed, and the molars tuberculated. The head is elongated, the face narrow and pointed, muffle naked, nostrils lateral, upper lip slightly cleft, and the ears moderate or very large; the posterior limbs considerably the longest; fore feet 5-toed, with rudimentary outer toes; hind feet with inner toe rudimentary or absent, the 2d and 3d joined even to the end and with small nails, the 4th very large, and the 5th moderate or rudimentary; tail usually short and clothed with small hairs, but sometimes long with very long hairs; pouch with its entrance commonly directed backward; mammæ 8 or less; stomach simple, and cæcum moderate. The largest are hardly of the size of a hare; they are found in Australia and Tasmania, and feed on insects and vegetable substances.—In the genus *macrotis* (Reid) the ears are very large, the tail long and covered with long hair, the tarsus long, the metatarsus hairy beneath, the innermost hind toe wanting, and the opening of the pouch directed foward. The rabbit-eared perameles (*M. lagotis*, Reid), of W. Australia, is 28 inches long, of which the tail is 10; ears about 4 inches; fur very long and soft, without admixture of spiny hairs, pale gray above, delicate vinous red on the sides, and white below. It is called native rabbit by the colonists of Swan river, where it abounds in the grassy districts, usually seen in pairs; it burrows in loose soil like the rabbit, retiring to its hole when pursued; the flesh is sweet, like that of the rabbit; its food consists of insects, especially of the larvæ of a large *buprestis* found at the roots of the acacia, equally relished by this animal and the natives. It is active in the evening, sleeping by day in a sitting posture with the head between the legs; it is of a savage disposition, even in captivity; it walks upon the hind legs widely separated, the tail assisting in the support of the body, and probably does not leap like the kangaroo.—In *perameles* (Geoffroy) the feet, tail, and ears are proportionately short; the fur has coarse hairs mixed with it; the tail is covered with very short hair; the pouch opens backward. The largest species is the thick-tailed bandicoot (*P. macroura*, Gould), 20 inches long, of which the tail is 7; fur moderately long and harsh to the touch, pencilled with black and yellow above, more yellowish on the sides, and yellowish white below; tail rat-like, with small stiff hairs, black above and brownish white below; it inhabits N. Australia. Other species are found in S. and W. Australia, many with the hair harsh, flattened, and sharp, and are generally called bandicoots.—In the genus *chœropus* (Ogilby) the fore feet have only 3 small, equal toes, with short compressed nails; hind feet with one well developed toe, the joined ones very small and high up, and the outer a mere tubercle, all with nails; muzzle long and pointed, ears very large, fore legs scarcely as thick as a goose quill, hind legs longer and about as slender; the pouch opening backward. According to Van der Hoeven, these are the only marsupials which have fewer than 5 toes on the fore feet. The pig-footed perameles (*C. castanotis*, Gray) is about 10 inches long to the root of the tail, the latter being 4 inches more; the fur is long, loose, and soft, brownish gray above, sometimes tinged with rusty, and yellowish white below; tail short-haired, black above and brownish white below; it inhabits S. Australia, making a nest, like other members of the family, of leaves and grass. Fossil remains of this family have been found in Wellington valley, Australia.

PERCEVAL, Caussin de. See Caussin.

PERCEVAL, Spencer, an English statesman, born in London, Nov. 1, 1762, assassinated in the lobby of the house of commons, May 11, 1812. He was the 2d son of John, earl of Egmont, by his 2d wife, the granddaughter of the 4th earl of Northampton, and was educated at Harrow and at Trinity college, Cambridge. In 1786 he was called to the bar of Lincoln's Inn, and in a few years was in possession of a lucrative practice. In 1796 he entered parliament for the borough of Northampton, which he continued to represent until the close of his life, and became a warm supporter of Pitt, whose favorable notice he attracted by a pamphlet on the force and extent of impeachments by the house of commons. So highly did Mr. Pitt esteem his financial abilities, that when about to fight a duel with Tierney he recommended, in case of his own fall, the appointment of Perceval as his successor. In 1801 he was appointed solicitor-general in the Addington ministry, and in 1802 attorney-general, in which capacity he conducted the prosecution in the celebrated case of Peltier, indicted for a libel on Bonaparte during the peace of Amiens. He retained his position upon the return of Mr. Pitt to office, and upon the accession of the Fox-Grenville ministry went into opposition. In 1807 he was appointed chancellor of the exchequer in the duke of Portland's cabinet, and upon the death of that nobleman in 1809 he succeeded him as first lord of the treasury. He met with his death at the hands of John Bellingham, an English merchant resident in Archangel, who, for some alleged injury by the Russian government, for which he had been unable to procure redress either from the British ambassador in St. Petersburg or from the British ministry, shot Mr. Perceval through the heart with a pistol. Bellingham had previously resolved on the destruction of the ambassador, whom he confessed he would have preferred to kill; but no opportunity occurring, he determined to shoot the first member of the administration who came in his way. He was subsequently tried for murder, and, notwithstanding an attempt to prove him insane, was convicted and hanged. Mr. Perceval's death caused a profound sensation, and upon the recommendation of the prince regent parliament settled an annuity of £2,000 upon his widow, and caused the sum of £50,000 to be vested in trustees for the benefit of his 12 children. He was a man of respectable abilities, but distinguished rather as a skilful lawyer and politician than as a great statesman. He was at one time the legal adviser of the princess of Wales, and was intimately connected with the preparation of the documents referring to the "delicate investigation," which were published in "The Book."

PERCH, Pole, or Rod (Lat. *pertica*, a long staff), a measure of length used in surveying land, equal to 5½ yards or 16½ feet. Surveyors' chains are commonly of 4 perches in length, sometimes of 2. In square measure 160 square perches make an acre, or 40 make one rood. In masonry a perch is equal to 25 cubic feet.

PERCH, a name properly restricted to the *percidæ*, a very extensive family of acanthopterous fishes, characterized by a covering of ctenoid scales, the freedom and small size of the infra-orbital bones, large mouth, many of the fin rays unjointed and inflexible spines, 7 branchiostegal rays, and the ventrals with 5 articulated rays and placed under or in advance of the pectorals. There are teeth on the vomer and generally on the palate, and the fins are always at least 7 and sometimes 8; the cheeks are not cuirassed, and there are no barbels on the lips; the stomach is cæcal, and its pyloric opening on the side; pancreatic cæca few and small, and the intestinal canal but little folded.—Leaving for works on ichthyology the consideration of the subdivisions of the perch family, only the typical genera can here be alluded to, and in the first place the genus *perca* (Cuv.), of which the common fresh water perch (*P. flavescens*) of America and the *P. fluviatilis* of Europe are familiar examples. The old genus *perca* of Artedi and Linnæus has been subdivided into 36 genera according to the number and shape of the dorsals, the characters of the teeth, the serrations of the gill covers and shoulders, size of the scales, and other characters. In the restricted genus *perca* of Cuvier there are 2 dorsals (the 2d flexible), all the teeth villiform without canines, the opercular bones serrated, the operculum spiniferous, and the tongue smooth; 14 species are described, all inhabitants of fresh water. The yellow perch (*P. flavescens*, Cuv.) is greenish yellow above, and golden yellow on the sides, with 7 transverse dark bands, widest above, and white below; centre of operculum deep green, iris golden, dorsals and caudal yellowish brown, pectorals yellow, and ventrals and anal scarlet. It attains a length of 12 to 15 inches and a weight of 2¼ lbs., though most specimens are below 10 inches; it is very generally distributed in the lakes, ponds, and streams of the northern and middle states and of the British provinces; it is easily taken by the hook or net, and is an excellent fish for the table. The *P. fluviatilis* (Linn.) is very common over Europe and most of the northern parts of Asia; the body above is greenish brown, passing into golden-yellowish white below, and on the sides are from 5 to 7 blackish bands; the dorsals and pectorals brownish and the other fins vermilion; it is a bold biter, and its flesh is excellent; it is voracious, omnivorous, and tenacious of life out of water; the female is very prolific, depositing an immense number of eggs united by a viscid substance into lengthened strings. In some allied species the single dorsal is deeply notched, and the villiform teeth are interspersed with canines.—There are some sea perches belonging to the genus *serranus* (Cuv.), with a single dorsal, canines, preoperculum rounded at the angle and smooth, 2 or more spines on operculum, and the jaws not scaly; there are 26 species, many of them handsome fishes, abundant in the warmer seas, and some of them known to the ancients under the name of *perca*. The allied genus *anthias* (Bloch), smaller, with brilliant colors and scaly jaws, was famous in ancient times, and, according to Aristotle, was called sacred by the sponge fishers, because no voracious fishes came to the places it frequented to annoy the divers. In other genera the dorsal is single and canines are absent, as in *centropristis* (Cuv.), which includes the fish often called black perch; this, with other fishes of the genera *labrax* (Cuv.), *grystes* (Cuv.), and others called white, ruddy, and sea perches, have been described under Bass. The bream (*pomotis vulgaris*, Cuv.) is often called pond perch; the white perch of the Ohio is the *corvina oscula* (Lesueur).—The salt water perch, conner, or chogset, so common around the rocky shores of New England and the British provinces, is a cyclolabroid fish of the genus *ctenolabrus* (Cuv. and Val.). In this fish (*C. cæruleus*, De Kay) the body is elongated and scaly, the preoperculum finely denticulated, lips thick and fleshy, a row of conical teeth in each jaw and a band of villiform ones behind these, the scales cycloid, and the anal fin with 3 spinous rays. It varies exceedingly in size and colors, being from 6 to 16 inches long; it is generally of a bluish color, but presents various tints of brown, rusty, coppery, reddish, or green, often with black dots, and irregular bluish lines on the head; the front teeth are larger than the others, and the upper jaw is very projectile; there is a single dorsal, with 18 strong spinous rays, with whose piercing power every school boy on the coast is familiar. It is an excellent fish for the table, and is generally fried; from June to October great quantities are taken in nets and by hook from boats, wharfs, and bridges, and always meet with a ready sale; they are kept alive in large floating cars through which the water constantly flows, whence the market is supplied; a string of these fish, of an average length of 8 inches each, cleaned and skinned, can be obtained for about a cent apiece.

PERCIVAL, James Gates, an American poet, born in Berlin, Conn., Sept. 15, 1795, died in Hazel Green, Wis., May 2, 1856. He early manifested a great fondness for literature, and at the age of 14 wrote a burlesque poem on the times. He was graduated at Yale college in 1815, and after teaching for a short time in Philadelphia began the study of medicine, with which he also joined botany. In 1820 he published a volume of poetry, which contained the first part of "Prometheus" and a few minor poems. Admitted to practice in the same year, he made two unsuccessful attempts to establish himself, the first in his native town, the second in Charleston, S. C., in which latter place he issued in 1822 the first number of the "Clio." This was a pamphlet of about 100 pages, consisting principally of verse with a few prose essays added, and was soon followed by a second part, composed entirely of verse. In 1824, through the influence of Mr. Calhoun, he was appointed assistant surgeon in the U. S. army, and was detailed to West Point as professor of chemistry in the military academy. As the duties were too laborious for him to find leisure for the pursuit of his studies, he soon resigned, and was made surgeon in connection with the recruiting service in Boston. There he contributed frequently to the "United States Literary Gazette," and edited several works, one of which was a republication of Vicesimus Knox's "Elegant Extracts." In 1827 he removed to New Haven, and the same year published the third part of "Clio," and began a revised translation of Malte-Brun's geography, which was not finished until 1843. He was also during the years 1827–'8 engaged in assisting in the preparation for the press of Webster's "Dictionary," a post for which his philological attainments admirably fitted him. His taste for natural history in general and for exploration had led him to take up the study of geology, and in 1834 he had made on his own account an examination of the ranges of trap rock in Connecticut. In the following year he was appointed, in connection with Professor Charles Shepard, to make a geological and mineralogical survey of the state. To this work Percival bent all his energies. He made a plan of the survey, and in the execution of it traversed the state so thoroughly that there was scarcely a spot in it which he had not visited; and at the time appointed for the report to be made the work was far from being finished. After considerable dissatisfaction another appropriation was ordered; and when at the expiration of the appointed period no report was forthcoming, insinuations against Percival became current. The idea of a full report was now abandoned, and after considerable difficulty, resulting partly from the enormous accumulation of materials, a condensed report of 500 utterly unreadable pages was published in 1842. About this time Percival occasionally contributed to the New Haven journals metrical versions of German, Slavic, and other lyrics, and in 1843 published "The Dream of a Day." The next 10 years, spent in retirement, were employed in his favorite studies, with debts constantly increasing, so that he was at one time forced in order to save his library from attachment to apply to his friends for aid; and about $2,000 then freely presented to him was subsequently repaid, both principal and interest. In 1853 an offer was made him by the American mining company to survey their lead mining region in Wisconsin, and in the following year he was appointed geologist of that state. The first report was published in Jan. 1855; and while he was engaged in the preparation of the second his health gave way, and after a gentle decline he died.—Percival's attainments in many branches of knowledge were of an extraordinary character. He was a diligent student of the principal modern languages of Europe, beside paying much attention to Gaelic, Welsh, the Norse and Slavic tongues; and at one time he made an elaborate report on the grammar of the Basque. He was one of the first of American scholars to welcome the researches of Bopp and Grimm, and other German philologists. With geography he was thoroughly acquainted, and was no mean proficient in botany, chemistry, and natural history. It is by his poetry, however, that he will be chiefly remembered. It has been collected and published (2 vols., New York, 1824; Boston, 1860). In his private character he was singularly modest and reserved, and troubled by a constitutional melancholy, which his experience in life tended rather to deepen than to remove.

PERCIVAL, Thomas, an English physician and moralist, born in Warrington, Lancashire, in Sept. 1740, died in Manchester, Aug. 30, 1804. He was educated at the Warrington academy, and in 1761 went to Edinburgh, where he studied medicine. Afterward he visited London, Paris, Hamburg, and Leyden, at which last place he received the degree of M.D. in 1765. In 1767 he settled at Manchester in the practice of his profession. He devoted much of his time to the investigation of subjects connected with medicine, and to his instrumentality the Manchester philosophical society owed its origin. In the latter years of his life he turned his attention to moral philosophy, and several of his works on that subject became very popular. In religion he was a dissenter. He wrote a large number of works, most of the earlier of which appeared originally in the "Philosophical Transactions" of London or Manchester, and were republished in 1767 under the title of "Essays, Medical and Experimental." Of his other works may be mentioned "Observations and Experiments on Water" (8vo., London, 1768); "Observations on the Poison of Lead" (8vo., 1774); and "Medical Ethics, or a Code of Institutes and Precepts adapted to the Professional Conduct of Physicians and Surgeons" (8vo., Manchester, 1803). Of his works on morals may be mentioned "Moral and Literary Dissertations" (8vo., Warrington, 1784), and "A Father's Instructions, consisting of Moral Tales, Fables, and Reflections, designed to promote the Love of Virtue" (8vo., London, 1788). After his death his collected works, with a memoir and selections from his correspondence, were published by his son (4 vols. 8vo., London, 1807).

PERCUSSION, in medicine. See Auscultation.

PERCUSSION CAP. See Fulminates.

PERCY, Thomas, D.D., an English prelate and scholar, born in Bridgenorth, Shropshire, April 13, 1728, died in Dromore, Ireland, Sept. 30, 1811. He was the son of a grocer, was educated at Christchurch college, Oxford, and having taken orders received in 1756 the rectory of Wilby and vicarage of Easton-Mauduit, Northamptonshire. His first literary production was the translation from the Portuguese of a Chinese novel entitled *Hau Kiou Choan* (1761), which was soon followed by "Miscellaneous Pieces relating to the Chinese;" a translation from the Icelandic into Latin and English of 5 pieces of runic poetry (1763); a new version of "Solomon's Song," with notes and a commentary (1764); and a "Key to the New Testament" (1765). He was now intimate with most of the literary men of his time, and in 1764 Dr. Johnson passed 3 months at his vicarage, where he found him eagerly engaged in preparing the collection of old songs and ballads to which he owes all his present celebrity. The "Reliques of Ancient English Poetry" appeared in 1765. The greater part of the collection was taken from an old manuscript in the editor's possession, and many other pieces were obtained from the Pepysian library. The reception of the book was not at first enthusiastic, but it procured for Percy the appointment of domestic chaplain to the duke and duchess of Northumberland in 1766, and chaplain in ordinary to the king in 1769. In 1778 he was made dean of Carlisle, and in 1782 bishop of Dromore in the county Down, where he passed the rest of his life engaged chiefly in the duties of his diocese. In his latter days he became totally blind. Dr. Percy was himself a poet of considerable merit. His "Nancy, wilt thou come with me?" and "The Hermit of Warkworth," a poem connected with the history of the noble family of Percy to which he was reputed to belong, are well known; and the beautiful ballad of "The Friar of Orders Gray," which appears in the "Reliques," is mostly his own composition. He also published in 1770 the "Northumberland Household Book," and a translation of Mallet's "Northern Antiquities."

PERCZEL, Móricz, a Hungarian general, born in the county of Tolna in 1814. He studied at Pesth, served for some time in a corps of military engineers, subsequently represented his native county at the diets of 1839–'40, 1843–'4, and 1847–'8, and after the revolution of March, 1848, was elected by the city of Buda a member of the new national assembly. Belonging to the extreme liberal or radical party, he became a favorite with the youth of the capital. On the approach of Ban Jellachich in September he formed a body of volunteers, and assisted by the militia of various south-eastern counties, as well as by Görgey, he compelled an isolated Croatian corps to surrender at Ozora (Oct. 7). This achievement raised him to the rank of general, and he subsequently acted with success on the Mur and Drave, and crossing the frontier made a short incursion into Styria. The advance of Windischgrätz in December caused the recall of his corps; but before he could join the retreating army of Görgey, he was suddenly attacked at Moor by Jellachich and his force entirely scattered (Dec.

29). He soon collected the remains of his corps, and undertook, in Jan. 1849, the defence of the left bank of the middle Theiss; but after well executed attacks on the Austrians at Szolnok and Czegléd, he was superseded by the Polish general Dembinski. In March he was sent to the south, relieved Peterwardein, stormed the ramparts of Szent-Tamás, the principal stronghold of the enemy, entered the Banat, and advanced as far as Pancsova (May 10). After numerous quarrels with other generals and the members of Kossuth's new administration, he was deprived of his command at the end of June. He collected a new body of volunteers, joined Wysocki at Czegléd in July, retreated with him toward Szegedin, and, again deposed, fought with Dembinski in the fatal battle of Temesvár (Aug. 9), after which he withdrew to Turkey, where he was for some time acknowledged as the head of a radical fraction of the Hungarian refugees. He repaired to England in 1851, and settled in the island of Jersey, where he still resides.

PERDICCAS, a general of Alexander the Great, and regent of the Macedonian empire, assassinated near Memphis in 321 B. C. He was descended probably from the royal house of Orestis, a Macedonian province, and early attached himself to the court of Philip, and at the time of the assassination of that monarch was one of the officers of his body guard. In the earlier campaigns of Alexander he commanded one of the divisions of the phalanx at the battles of the Granicus, Issus, and Arbela, was subsequently transferred to the command of a division of the horse guards, and was frequently employed in separate commands, not only in connection with others, but as sole general. When Alexander made a distribution of honors at Susa, Perdiccas received for his services a crown of gold, and a daughter of the satrap of Media in marriage. After the death of the king, he bore a prominent part in the troubles which followed between the cavalry and the infantry, and after the settlement of the quarrel he was made regent under the title of chiliarch of the horse guards. In this position he succeeded in crushing Meleager, his co-regent, with all of his principal partisans. Although feared and hated by the other leading generals, he managed for a time to retain his power in security. A revolt of the Greek soldiers in the upper provinces of Asia was put down by Pithon, one of his officers. In 322 B. C. he invaded Cappadocia, defeated its satrap Ariarathes in two battles, and having reduced the country intrusted its government to Eumenes. Afterward he marched into Pisidia, and captured Laranda and Isaura. He proposed to marry Nicæa, daughter of Antipater, and put to death Cynane, the half sister of Alexander; but this aroused so much indignation among the soldiers, that he was forced to marry her daughter to the king Arrhidæus. An attempt to bring Antigonus to account for his conduct in the management of his government led to hostilities. Antigonus fled to Macedonia, and Antipater, Craterus, and Ptolemy formed a league and declared war against Perdiccas. He determined to attack Ptolemy, and, leaving Eumenes behind in command in Asia Minor, set out for Egypt, and marched as far as the Nile without opposition. In attempting to cross that river he was repeatedly repulsed, and in the last effort lost so many men that the discontent in his army, which for a long time had existed in secret, broke out in open mutiny. A number of officers, headed by Seleucus and Antigenes, went to his tent and there despatched him. Perdiccas was reputed a man of great military talents and personal courage; but his disposition was crafty and cruel, his ambition grasping and unscrupulous.

PERDIDO, a small river and bay, which form the W. boundary of Florida, separating Escambia co. in that state, from Baldwin co., Ala. Perdido bay is more properly a lake, into which the river expands near its mouth. It is landlocked, and its outlet into the gulf of Mexico is so small, and enters at so acute an angle with the line of coast, as to be almost undistinguishable from sea, from which circumstance the river probably derived its Spanish name *Perdido*, or "lost." There are generally but 4 or 5 feet of water on the bar at its mouth. The Perdido was noted from a very early period as the boundary between the French and Spanish colonies of Louisiana and Florida.

PÈRE DUCHESNE. See Hébert.

PEREGRINE FALCON. See Falcon.

PEREIRA, Jacobo Rodriguez, a Spanish instructor of deaf mutes, of Jewish family, born in Berlanga, Estremadura, in 1715, died in Paris in 1780. He opened a school for deaf mutes at Cadiz, but was not able to maintain it, and about 1742 removed with his family to Bordeaux. In 1745 he taught a mute in Rochelle to pronounce some words. This coming to the knowledge of D'Azy d'Étavigny, the comptroller of that city, he begged him to undertake the education of his deaf-mute son. Pereira consented, and the next year addressed the academy of sciences in Caen on the results of his instruction. After some years he appeared before the academy of sciences in Paris with young D'Étavigny, whose proficiency excited their admiration. A few months later he appeared with his pupil before Louis XV. The king examined the youth very thoroughly, and was so much pleased with his proficiency, that he bestowed on Pereira a pension of 800 francs. In 1754 he presented one of his pupils before King Stanislas of Poland. Several of his pupils were distinguished in the subsequent history of France. One of them, Saboureux de Fontenai, wrote an account of his teacher's manner, and the thoroughness of his instruction. (See Deaf and Dumb.)

PEREIRA, Jonathan, an English physician and pharmacologist, born in London, May 22, 1804, died there, Jan. 20, 1853. At the age of 14 he was apprenticed to a surgeon and apothecary, in 1821 attended the Aldersgate street dispensary, in 1822 became a pupil of St. Bartholomew's hospital, and in March, 1823, received a license to practise from the society of apothecaries. On his appointment not long after as apothecary of the Aldersgate street dispensary, he became a private tutor, and published a number of works, chiefly for the use of students about to be examined. He translated the Latin pharmacopœia of the London college of physicians, and published a number of Latin prescriptions under the title of *Selecta e Præscriptis*. Turning his attention to chemistry, he compiled "A General Table of Atomic Numbers," and in 1826 was appointed lecturer in chemistry in the Aldersgate street school of medicine. The lectures which he subsequently delivered on materia medica were originally published in the "Medical Gazette," and in 1839 were revised and republished under the title of "Elements of Materia Medica and Therapeutics." To this work he owed his reputation. In 1840 he received the degree of M.D. from the university of Erlangen, became the same year assistant physician to the London hospital, was subsequently admitted as a London licentiate of the college of physicians, and in 1845 was elected fellow of the college. In 1842 he published a work on "Food and Diet." In 1851 he was made full physician of the London hospital. Beside the works already mentioned, which were chiefly compilations, he published several original treatises in various medical and pharmaceutical journals, and wrote a series of "Lectures on Polarized Light." At the time of his death he was examiner at the London university.

PEREIRA DE SOUZA. See Caldas Pereira de Souza.

PEREIRE, Émile and Isaac, French financiers of Jewish origin, born in Bordeaux, the former in 1800, the latter in 1806. They are brothers, and grandsons of Jacobo Rodriguez Pereira. Having removed to Paris and entered into business, they became ardent votaries of Saint-Simonism. They wrote for various journals, including the *Producteur*, the *Globe*, the *National*, the *Temps*, the *Journal des connaissances utiles*, and the *Journal des débats*, in the last of which Isaac originated a daily report of the bourse. Under the guaranty of the Rothschilds they obtained the contract for building the St. Germain railroad, of which Émile was the originator; and afterward under the same auspices they constructed the more important northern railroad. They built the *chemin du midi* and the *canal latéral* on their own responsibility. The *crédit mobilier* was founded in 1852, chiefly through their agency, and they have since been prominently concerned in its management. (See Crédit Mobilier.)

PEREZ, Antonio, a Spanish statesman and author, born at Monreal de Ariza, Aragon, in 1541, died in Paris, Nov. 3, 1611. He was a natural son of Gonzalo Perez, minister for 40 years to Charles V. and Philip II., was legitimated in his infancy, and educated at Louvain, Venice, and Madrid. On his father's death he became one of the two chief secretaries of state. Adroit, industrious, and a skilful and unscrupulous politician, he soon became the depositary of Philip's most intimate confidences. When the king wished to put out of the way Juan de Escovedo, the secretary and adviser of John of Austria, whom he suspected of designs upon the crown, Perez was employed to have him assassinated (1578). Escovedo was stabbed in the street by hired bravos, but it is now believed that Perez had a personal motive in causing his death, because Escovedo was acquainted with the minister's intrigue with the princess of Eboli, the king's mistress. However this may be, Perez and the princess were arrested 2 months afterward, ostensibly to satisfy the demands of Escovedo's relatives, and the former was condemned to 2 years' imprisonment, 8 years' exile from court, and a heavy fine. At first Philip appeared anxious to make his punishment as light as possible, and assigned his own house as the place of confinement; but after he had obtained all the papers which might prove his own share in the murder, he sent the ex-minister to the fortress of Turreguano, and extorted from him on the rack a confession that he had killed Escovedo, coupled however with the declaration that he did it by the royal command. Perez would probably have lost his head but for the devotion of his wife, who in July, 1590, procured him the means of escape to Saragossa, where he placed himself under the protection of the *fueros* or independent jurisdiction of Aragon. The king, in violation of these constitutional privileges, ordered him to be seized, but the people forcibly released him. Philip then caused him to be transferred to the prison of the inquisition on a charge of heresy. The populace again restored him to liberty, and the consequence was an armed revolt which gave Philip a long desired opportunity to extinguish the *fueros* for ever. In the mean time he escaped to France, and was sent by Henry IV. on a secret mission to England, during which he published a narrative of the occurrences in which he had been concerned; but such was his dread of Philip, who indeed attempted several times to have him assassinated, that he expressed himself in a guarded and enigmatical way, which has contributed to render the whole affair one of the most mysterious romances of history. Recalled to France in 1595, he received a house for his residence and a guard to protect him, and in the same year was again sent to England. After the accession of Philip III. his wife and children, who had been kept in prison, were liberated (1599), but all his efforts to be recalled to Spain were in vain. He undertook a third mission to England in behalf of his native country in 1604, but miserably failed, and returning to France passed his last days in penury. Beside his *Relaciones* already mentioned, he wrote *Cartas familiares*, several political works, and a life of Philip II. which has never been printed. A collection of his works appeared at Geneva in 1654. His style, particularly in his letters, is often faulty and overstrained, but abounds in passages of eloquence and pathos, and in pointed sayings, many of which have become proverbial. He wrote in remarkably idiomatic Castilian. Much light has been thrown upon his career by M. Mignet in his *Antonio Perez et Philippe II.* (Paris, 1845; translated into English in 1846).

PERFUME, a term applied to the scent arising from odoriferous bodies, and also to these bodies themselves when they are prepared especially for the sake of their agreeable odor. The art of preparing them is called perfumery, and by the French is made to include the compounding of a great variety of articles for toilet use, as pomades, hair powders, oils, depilatories, cosmetics, dentifrices, soaps, &c., all of which are scented by the introduction of various perfumes. From the most ancient times perfumes of various sorts have been held in high estimation. They exert a pleasant influence upon most persons, though to a few they are offensive. Solomon (Prov. xxvii.) remarks that "ointment and perfume rejoice the heart." They were prescribed as medicines by Hippocrates, Criton, and other ancient physicians. It is affirmed that after the destruction of the clove trees by the Dutch in the island of Ternate, the colony suffered from epidemics unknown before; and in times when the cholera has prevailed in London and Paris, those employed in the perfumery factories have escaped its ravages. The Egyptians prepared them for different purposes, as for embalming the dead, as offerings to the gods, and for domestic uses. They anointed their bodies with oil, and it was the custom to pour sweet-scented oils upon the heads of newly arrived guests. In their tombs are found boxes of alabaster, onyx, glass, ivory, &c., in which the ointments were kept. One of these now in Alnwick castle contains an ointment of which the scent is still retained. The perfumes employed in embalming are also preserved in the mummies. (See EMBALMING.) The Egyptians obtained the materials of their perfumes, such as bitter almonds and origanum, from their own soil, and also imported perfumes from Arabia and India. In the Old Testament frequent reference is made to the use of perfumes by the Hebrews. The sweet incense burned upon the altar was a perfume; and "the art of the apothecary," or as some read it "perfumer," is distinctly named in Exod. xxx., where Moses is directed to prepare the oil of holy ointment from the principal spices, myrrh, sweet cinnamon, sweet calamus, cassia, and olive oil; and also to prepare a perfume of other spices named near the close of the same chapter. See also Psalm xlv. 8, Prov. vii. 17, Cant. i. and iv., Jer. vi. 20, and various other places; and in the New Testament (Mark xiv.), the story of the woman with the alabaster box of precious ointment. Other nations of antiquity, as the Phœnicians, Assyrians, and Persians, are known to have made great use of perfumes; and Tyre was a famous mart whence they were exported by sea, as Babylon was for the supply of the interior (Ezek. xxvii.).—The art of perfumery was practised to an extraordinary extent by the ancient Greeks and Romans. The odor of perfumes was an offering to the gods, and the apparition of these was always represented as accompanied by an ambrosial fragrance. Oils, pomatums, and other perfumes were made in great profusion and most lavishly used. After bathing and in their athletic exercises the Greeks applied them liberally to their persons; and, as Seneca states, it was their custom to anoint themselves twice or even thrice a day in order that the delicious fragrance might never cease. To such an extent was this carried, that Solon enacted a law forbidding the Athenians to use them. Their wines were perfumed by infusing in them roses, violets, and hyacinths—the first step, perhaps, in the preparation of alcoholic perfumes. Capua was especially celebrated for its perfumes. One of its principal streets, called the Seplasia, it is stated, was made up entirely of shops devoted to this trade; and it was also largely carried on in several other towns of Greece and southern Italy. Pliny in his "Natural History" has given a very full account of the extraordinary varieties of perfumes in use by the Romans under the emperors. The perfumers (*unguentarii*) were mostly Greeks, and occupied a special quarter of the city. Their shops were supplied with aromatics from all parts of the known world, and were a favorite resort for fashionable loungers. Their productions were quite as numerous as the perfumes of the present day, and much more profusely used. The same taste continued under the Greek emperors; and in the oriental church the consumption of aromatics was so great, that at one time a tract of land of 10 square miles in Syria was especially devoted to the production of incense trees. The Arabs introduced their use into Spain with many curious receipts, some of which are still preserved and are supposed to have been handed down from the Egyptians. In the middle ages France and Italy were most conspicuous for the manufacture and use of perfumes. Incense and fragrant tapers were consumed in the Catholic churches even as far back as the baptism of Clovis, the first Christian king of France, in 496. Charlemagne made use of perfumes, and Philip Augustus in 1190 granted a charter to the master perfumers. Alcoholic perfumes are supposed to have been first made in the 14th century; and the first of these of which we have an account is Hungary water, distilled from rosemary in 1370 by Elizabeth, queen of Hungary, who received the receipt from a hermit, and by the use of it is said to have preserved her beauty to old age. Catharine de' Medici, when she came to France to marry Henry II., brought with her a famous Florentine perfumer named René, and from that time the French made great progress in the art; but from the receipts that have been preserved it appears that their processes were very rude and unscientific. In England a taste for perfumes appears to have been prevalent in the time of Shakespeare; and in that of Dean Swift the shops of the perfumers were the resorts of loungers, as they were in ancient Rome:

> First issued from perfumers' shops
> A crowd of fashionable fops.

But their use must afterward have declined, for in Chambers's "Cyclopædia," published in 1740, it is stated that perfumes were disused there, but were *à la mode* in Italy and Spain. At the present time the manufacture of perfumes is chiefly carried on in Paris and London, and in various towns near the Mediterranean, especially in the south of France. The fruits and flowers of those sunny regions afford the greatest variety of fragrant odors, and certain districts are famous for their peculiar productions; as Cannes for its perfumes of the rose, tuberose, cassia, jasmine, and the neroli, extracted from the leaves of the bitter orange; Nîmes for thyme, rosemary, aspic, and lavender; Nice for the violet and reseda; and Sicily for the lemon, bergamot, and orange. In England some of the essential oils are prepared from native herbs upon a large scale, as at Mitcham in Surrey, where a ton of peppermint and of lavender is sometimes distilled at once. In the northern United States many of the essences and essential oils are also largely prepared, the woods furnishing the wintergreen, sassafras, and other sweet-scented plants, and the gardens the peppermint, rose, &c. In London, it is stated, there are about 40 manufacturing perfumers, employing each from 20 to 100 hands; and the total annual value of their productions is believed to be fully £1,000,000. A large portion of this consists of fancy soaps, which are exported in great quanties to the United States. In Paris there are about 80 perfumers, employing from 2,000 to 3,000 hands; and the export trade averages annually from 12,000,000 to 13,000,000 francs, having doubled in the last 25 years. The home consumption probably equals in value the foreign exports. —Perfumes are derived from a great variety of flowers, fruits, seeds, woods, and other vegetable products; and by the skilful combining of different scents, some are obtained that imitate the odor of flowers which are not themselves used in perfumery. But it is not from plants alone that perfumes are obtained. At the close of the article ESSENTIAL OILS allusion is made to the strange sources which by the aid of recent chemical discoveries have been made to furnish some of the choicest perfumes. The delicate scent of flowers has been traced to certain oils and ethers, which can be elaborated from substances associated only with the most disgusting odors. The fetid fusel oil by different methods of treatment produces oils not to be distinguished from those of various fruits; the noisome oils of gas tar are made to yield the nitro-benzole known as the oil of bitter almonds or essence of mirbane, which is now extensively used for perfuming soap, and is even preferable for confectionery and culinary uses to the genuine article (unless this is distilled over potash), as it contains no prussic acid; and from the drainage of cow houses is extracted an essential ingredient in the famous *eau de mille fleurs*. A new and unlimited field is thus opened for the artificial production of perfumes; and it is believed that by the employment of a few common essential oils and the organic radicals, all the odors in the vegetable, animal, and mineral kingdom may be successfully reproduced. The perfumes derived from animal sources are musk, civet, ambergris, hartshorn, &c. The ambergris, though having little scent itself, imparts a most ethereal and delicate odor to other perfumes. In an elaborate paper upon perfumery furnished by Mr. Eugene Rimmel to the society of arts of London, and published in No. 391 of their "Journal" (May 18, 1860), scents in general use are classified in 18 groups, and the vegetable products used in this art are arranged in 10 divisions, as follows: 1, the floral series, viz., jasmine, rose, orange flower, cassia, tuberose, violet, jonquil, and narcissus; the attar or otto of roses (see ATTAR OF ROSES) is the most valuable product of this division; 2, the herbal series; 3, the *andropogon* series, a genus of plants of this name in Ceylon, which furnish the lemon grass, citronella, and ginger grass oil; 4, the citrine series, comprising the bergamot, orange, lemon, cedrat, and limette, from whose rinds an essential oil is obtained by expression or distillation; 5, the spice series, including cassia, cinnamon, cinnamon leaf, cloves, mace, nutmeg, and pimento; 6, the wood series, consisting of sandal wood, rose wood, rhodium, cedar, and sassafras; 7, the root series, comprising orris root and vetivert, of which the latter, called by the Hindoos *kus-kus*, the root of the *anatherum muricatum*, is made in India into mats and blinds, which being often watered and exposed to the sun shed a most agreeable and lasting perfume; 8, the seed series, composed of aniseed, dill, and caraway; 9, the balm and gum series, including the balsams, camphor, myrrh, and other gums; 10, the fruit series, including bitter almonds, Tonquin beans, and vanilla. The artificial preparations, above referred to, and the animal perfumes make two more series. The greatest number of the materials, amounting to 28, is obtained from the south of France and Italy, which is the chief centre of manufacture for perfumery materials. The East Indies and China furnish about 21, Turkey 2, Africa 2, North America 6, South America 6, and England 4. The only articles named from the United States are peppermint, sassafras, and wintergreen.—The manufacture of perfumes in the south of France is extensively carried on in the towns of Grasse, Cannes, and Nice. In Grasse about 70 establishments are engaged in this business and in distilling essential oil, and in the other two towns about 80 houses more. The quantities of materials annually consumed and their values are thus approximately estimated:

Orange flowers	1,700,000	lbs.,	worth	about	$161,000
Rose flowers	430,000	"	"	"	80,000
Jasmine flowers	110,000	"	"	"	60,000
Violets	62,000	"	"	"	35,000
Cassia	66,000	"	"	"	50,000
Tuberoses	52,000	"	"	"	13,000

The manufactured articles consist of

Scented pomades and oils, about	600,000	lbs.,	worth	about	$1,250,000
Rose water, about	178,000	"	"	"	25,000
Orange flower water, 1st quality, about	1,110,000	"	"	"	120,000
Orange flower water, 2d quality	2,250,000	"	"	"	225,000

These do not include the essential oils, some of which are very valuable, the neroli, for instance, being worth about $50 per lb. The supply of these articles is insufficient for the demand, and as the crop of some one of the flowers occasionally fails, the manufacturers are put to serious inconvenience. It is hence recommended to foster the extension of the trade into other countries, where the flowers might be successfully cultivated; as in Spain, Portugal, and various tropical countries in both hemispheres.—Several methods are in use for extracting the odoriferous properties of plants, and imparting these to spirits or greasy bodies. Some of the processes are noticed in the articles EAU DE COLOGNE, ESSENTIAL OILS, and EXTRACTS. In the preparation of pomades the best fat employed is the marrow of the ox; but a cheaper fat is often substituted for it, or a mixture of beef or veal fat and lard. These are beaten in a mortar, melted in a water bath, and then strained. Before the mixture cools the essential oil selected for the perfume is added and stirred in; or the flowers themselves are thrown in and left to digest for several hours, when they are taken out, the fat is again heated and strained under pressure, and fresh ones are put into it; and this is continued for several days till the grease has sufficiently imbibed the odor. It is then strained in cloth bags. This process is called maceration. Inodorous oils, such as the oil of behn, described by Piesse in his work on perfumery, are well adapted for taking up the perfumes of flowers by this process. Pure olive oil is largely used for this purpose in the south of Europe. But for delicate plants, such as the jasmine, tuberose, and cassia, the odoriferous principle of which would be injured by the heat, the process in use is that of absorption or *enfleurage*. Square wooden boxes are provided having bottoms of glass plate. Upon these is spread a layer of purified lard and suet mixture, and upon this freshly gathered flowers are spread every morning, as long as the flower is in bloom. The boxes are kept shut, and the grease finally acquires a very strong odor. To aromatize oil in the same way, the boxes have a wire bottom upon which cotton cloths soaked in the oil are laid, and the boxes or frames are piled upon each other to keep them close. When a number of cloths are charged with the perfume, they are subjected to the action of a press for recovering the oil. Spirits are scented by maceration or by digesting them with essential oils in a water bath and agitating them at times for several days. The *eau de mille fleurs* is prepared on this plan in Paris with the following ingredients and proportions: alcohol, 6 litres; orange flower water, 4 litres; balsam of Peru, 60 grammes; essence of bergamot, 120 grammes; essence of cloves, 60 grammes; essence of neroli, 15 grammes; essence of thyme, 15 grammes; essence of musk, 190 grammes. The last named essence is prepared by digesting in the heat of the sun for 2 months 15 grammes of civet and 75 grammes of musk in 2 litres of alcohol perfumed with ambergris. Scented vinegar is prepared in a similar way, vinegar being substituted for alcohol. Another method of preparing perfumes has recently been discovered and introduced by M. Millon, a French chemist. He found that the aromatic principle of vegetable matters might be extracted together with some fatty or waxy matters by treating them with purified ether or sulphuret of carbon; and that by evaporating the volatile solvent at a temperature below that of the surrounding atmosphere, the perfume is retained and fixed in the residuum without undergoing any change. The substance deposited by the treatment of different plants is variously colored; it is sometimes solid, or oily or semi-fluid, becoming solid after some time. The solvent may be collected as it condenses in the distillation, and the same may be used several times over; but it should always be for the same flower, and with the same apparatus. The choicest parts of the plants or flowers are carefully selected in this process, and used exclusively, by which mode much more delicate results are attained than by the ordinary mode of distillation. A remarkable peculiarity of the perfumes thus prepared is that they may be kept open to the air without being dissipated and lost. They may be separated from the waxy matter by alcohol, which dissolves them together with a little of the oily and coloring matters; and in this state they may be conveniently mixed with fats and oils.—Pastilles are articles of perfumery made when set on fire to consume slowly and give out the odor with which they are charged. They are composed of charcoal finely pulverized, saltpetre, and the odoriferous substances, chiefly gum resins, the whole moulded into little cones, which are made to adhere together by the addition of mucilage. The *pastilles du serail* consist of 24 grammes of olibanum, 24 of storax, 16 of nitre, and 124 of pulverized charcoal. For rose pastilles there are added to the above 32 grammes of rose leaves and 2 of essence of rose; for orange flower pastilles 24 grammes of galbanum, 32 of dried pulverized orange peel, and 2 of essence of neroli; for vanilla, 24 grammes of galbanum, 16 of cloves, 32 of vanilla, 1 of essence of cloves, and 16 of essence of vanilla. Odoriferous spirits for burning are prepared in a similar way, the vanilla being generally replaced by gum benzoin.—The powdered almond paste used in perfumery is prepared from the residue of the bruised kernels of apricots or almonds, sweet or bitter, after the oil is pressed out. This is ground and sifted. The paste is variously prepared from the powder. One process is to mix together 250 grammes each of the powder and of honey, with 500 grammes of the oil of bitter almonds and the yolks of 4 eggs. Perfumed soaps are prepared by substituting pomade for the grease in mixture with soda lees.

PERGAMUS, or PERGAMUM. I. The name of the citadel of Troy, frequently used by poets for that city itself. II. An ancient city of Asia Minor, in the Mysian district of Teuthrania, and capital of a kingdom of the same name. It was built in the delightful valley of the Caïcus, at the foot of two hills near the N. bank of that river, and at its confluence with the Cetius and Selinus, the latter of which flowed through the city. The acropolis was built on one of the hills. Pergamus was founded by a colony of Arcadians, or, according to other traditions, by Epidaurians under Æsculapius, who was worshipped as the patron of the place. Its name is derived by some from that of Pergamus, the son of Pyrrhus and Andromache, who is said to have slain a Teuthranian king in single combat and taken possession of his territory. Having belonged successively to the Persians, the empire of Alexander the Great, and the Thracian kingdom of Lysimachus, it was betrayed by Philetærus, the commander of the strong citadel, where Lysimachus had deposited his treasures, into the hands of Seleucus I. of Syria. When Seleucus died, Philetærus made himself independent (280 B. C.). His nephew and successor Eumenes I. (263–241) extended his dominion over parts of the neighboring provinces, having vanquished Antiochus Soter in a battle near Sardis. Attalus I. (241–197), a cousin of Eumenes, routed the invading Gauls, assumed the royal title, and assisted the Romans in their wars against the Achæans and Philip of Macedon. His son Eumenes II. (197–159) supported the Romans against Antiochus the Great, and after their victory at Magnesia (190) was rewarded by the annexation to his dominions of the whole of Mysia, Lydia, Phrygia, and other neighboring provinces. Pergamus now became one of the most splendid cities of Asia, rivalling by its library, a renowned school of literature, and the invention of parchment, the principal glories of the capital of the Ptolemies. Attalus II. (159–138), the brother of Eumenes II., maintained his alliance with Rome, and like his predecessors was a promoter of science and literature. His nephew, Attalus III. (138–133), ruled like a madman, destroying his own relatives, and finally bequeathed his whole kingdom to the Romans, who after a contest with Aristonicus, a natural son of Eumenes II., erected it into the province of Asia, of which Pergamus became the splendid capital. It afterward decayed, however, being deprived of its treasures of literature by Antony, who attached them to the library of Alexandria, and subsequently also of its dignity as capital of the province under the Byzantine rule. It was one of the principal Asian seats of Christianity in its earliest period. It was finally destroyed during the Turkish wars, but its extensive ruins, including remains of temples, a theatre, and an amphitheatre, are still visible.

PERGOLESI, GIOVANNI BATTISTA, an Italian composer, born at Jesi, in Ancona, in 1710, died at Torre del Greco, near Naples, in 1737. He was educated at the Neapolitan conservatory *dei poveri in Gesu Cristo;* but discovering that in this institution taste and melody were sacrificed to pedantry, he left it at the age of 14, and received lessons in vocal composition from Vinci and Hasse. At 20 years of age he procured an engagement at the *teatro nuovo*, Naples, for which he wrote comic intermezzos, including the *Serva padrona*, subsequently produced with great enthusiasm at Paris. In 1735 he brought out at Rome his opera of *Olympiade*, which was coldly received, notwithstanding it was highly commended by contemporary musicians. His sacred compositions were better appreciated, and few works of their class have been more admired than his mass in D, containing the celebrated *Gloria in Excelsis*, and his *Dixit Dominus* and *Laudate.* Two years before his death his health began to fail rapidly, and by the advice of his friends he removed to Torre del Greco, near the foot of Mt. Vesuvius. Here during his last illness he composed his cantata of *Orfeo ed Euridice*, his *Salve Regina*, and his celebrated *Stabat Mater.*

PERIANDER, tyrant of Corinth, succeeded his father Cypselus probably about 625 B. C., died about 585 B. C. At first his reign was mild, but afterward became exceedingly inhuman and oppressive. Herodotus says that Periander sent a herald to Thrasybulus, tyrant of Miletus, to ask him what mode of government it was safest to adopt in order to rule with security. Thrasybulus, making no direct reply, took the messenger into a corn field, and walking through it broke off and threw away all the ears that overtopped the rest. Periander understood the meaning of the action, and thenceforth constantly depressed the power of the higher orders by putting to death or banishing prominent citizens. Although the particular incidents of his reign are all or nearly all of doubtful authenticity, it seems to be a fact that his administration, supported by a powerful body guard, was exceedingly rigorous, that he suppressed common tables, clubs, and public education, shed much blood, and made exorbitant exactions. On one occasion it is said that the women of Corinth, whom he had invited to a religious festival, were stripped by his order of their rich attire and ornaments. Later writers depict him as the foe of luxury and dissolute habits, preventing the great accumulation of wealth by individuals, punishing also those who squandered their property, and once ordering the procuresses of Corinth to be thrown into the sea. By Aristotle he is spoken of as the first who brought to a system the art of ruling despotically. His foreign policy was vigorous and successful. According to Herodotus, deceived by a scandalous report, he had put to death his wife Melissa, the daughter of Procles, tyrant of Epidaurus, though he was warmly attached to her; and when in after years his two sons visited the court of the latter, their grandfather told them the manner of their mother's death. The younger son, Lycophron, on his return refused to have any intercourse with his father; whereupon Periander sent him away to Corcyra, invaded Epidaurus, reduced it, and took Procles prisoner. Afterward he endeavored to persuade Lycophron to return and take charge of the kingdom; and finally the latter consented on condition that his father should abdicate and live in Corcyra. But the inhabitants of that city, wishing to keep Periander away, put his son to death. Periander is said to have died of grief, after having lived about 80 years. He was an encourager of poetry and music, and was usually reckoned among the seven sages of Greece, although some placed in his stead Myson of Chenae in Laconia. Arion and Anacharsis were patronized by him, and by Diogenes Laërtius he is said to have written a didactic poem of 2,000 verses. He was succeeded by a relative, Psammetichus, son of Gordias.

PERICARDITIS. See HEART, vol. ix. p. 12.

PERICLES, an Athenian statesman, born at Athens about 495 B. C., died there of the plague in 429. He was of an ancient and noble family; his father was Xanthippus, who, with the Spartan general Leotychides, defeated the Persians at Mycale; his mother was Agariste, niece of Clisthenes, who expelled the Pisistratidae from Athens. On the father's side he was connected with the family of Pisistratus, and on the mother's side he was descended from the princes of Sicyon and the Alcmæonidæ. When the Messenians rose against Sparta in 464 B. C., and fortified themselves on Mt. Ithome, the Spartans invoked the aid of the Athenians to reduce the place. Cimon, the leader of the aristocracy at Athens, and the greatest commander of his time, was sent with a large force in answer to the appeal. But he failed to reduce the fortress, was slighted by the Spartans, and returned home in disgrace. The popular party was then led by Pericles, between whom and Cimon there existed a hereditary feud; for it was Xanthippus, the father of Pericles, who had impeached Miltiades, the father of Cimon. Taking advantage of the unpopularity which the ill fortune at Mt. Ithome brought upon Cimon and the aristocracy, Pericles caused a measure to be carried in the popular assembly, by which the court of the areopagus was nearly shorn of its political power. This was a fatal blow to the aristocracy, and constituted, with other changes, a political revolution. Among these changes were the institution of dicasteries or jury courts, in which jurors were paid for their attendance, and the almost complete abrogation of the judicial power of the senate of 500. The tablets containing the laws of Solon were transferred from the acropolis to the neighborhood of the market place, as if to signify that the guardianship of the laws had passed into the hands of the people. The ascendency of Pericles and the popular party thus established cost many a violent struggle. The poet Æschylus enlisted all his powers, in the drama of the "Eumenides," against these innovations; but his opposition resulted only in his own flight from the city, while Cimon himself, who, in the struggle between the aristocratic and democratic parties, had before narrowly escaped banishment, was soon after driven into exile by ostracism (about 459). On the other hand, Ephialtes, a leader, with Pericles, of the popular party, a man of rigid integrity, who had been most conspicuous in the passage of the obnoxious measure against the areopagus, was, about the time of Cimon's recall from banishment (453), assassinated by a Bœotian emissary of the aristocracy. The humbled aristocracy afterward united themselves under the party lead of Thucydides, the son of Melesias. In the popular assembly they were drilled into a compact party organization, occupying seats together instead of being mixed up with the general mass of citizens. Thus their applause or dissent could be made more effective, and in debate they could concert their measures and use their strength to the best advantage. But this concerted action soon brought suspicion upon them, which passed, on account of the fewness of their number, into contempt. They complained of the administration of Pericles, that the fund derived from the confederacy of Delos, intended for purposes of general defence against the Persians, had been misapplied in the adornment and strengthening of Athens. Pericles claimed the right to use in this way so much of the public treasure as was not needed for the common defence. He was sustained, and Thucydides driven into banishment. This annihilated the aristocratic party, and left to Pericles the undisputed conduct of affairs. He had succeeded to the political principles of Themistocles, and he labored first to make Athens the capital of Greece, the centre of political power and influence, and the seat of art and refinement; and secondly to elevate the public spirit of his countrymen. He gave respectability and value to the elective franchise by setting close guards against a fraudulent abuse of it, and thus made even the humblest citizen feel something of the dignity of Athenian citizenship. He trained the people in naval affairs by sending out every year a squadron of 60 triremes to cruise for 8 months in the Ægæan. He planned great architectural works to embellish and strengthen the city. He built the Odeon for theatrical exhibitions, and the Parthenon with its splendid approach called the propylæa. To render secure the communication of Athens with the sea, chiefly through his advice, the long walls had been built which stretched to the Piræus and Phalerum; and to increase this security he afterward added a third wall, and improved and beautified the Piræus. He further provided for the poorer classes and strengthened the state by an enlightened system of colonization. For the entertainment of the people he added to the pomp and magnificence of popular spectacles, established new ones, and made the theatres and public festivals accessible to the poorer classes. He democratized the legislative and judicial functions of government by paying jurors and legislators. Nor even were the higher classes sacrificed that the democratic element might be fostered. Literature, architecture, painting, and sculpture rose under him to the highest perfection. In his foreign policy he aimed at the aggrandizement of Athens and the extension and consolidation of her sway. Beginning as an ally, he in a few years reduced a portion of the confederate states to the condition of tributaries, and bound the rest to military service and a conformity of foreign policy. Upon each of the subject states he imposed a democratic form of government, and transferred important trials from the local courts to the tribunals of the capital. The annual tribute or contribution to the confederate fund, the custody of which had already been transferred from Delos to Athens, he raised from 460 talents ($500,000) to 600 talents, although the object of its establishment, namely, to resist a Persian invasion, no longer occupied the public mind. During his administration, 1,000 Athenians were settled in the Thracian Chersonese, 500 in the island of Naxos, and 250 in the island of Andros. He appropriated the Greek city of Sinope, on the shores of the Euxine, for the maintenance of 600 Athenian citizens. The islands of Lemnos, Imbros, and Scyros, together with a large tract in Eubœa, were covered with Athenian proprietors. Colonies were planted at Thurii in Italy, near the site of the ancient Sybaris, and at Amphipolis in Thrace. To the former, foreigners were invited from all parts of Greece.—The overshadowing influence of Pericles made him an object of envy, jealousy, and hatred. His public and private life were both in turn assailed. When the Peloponnesian war impended, the hostile faction succeeded in exciting the public mind against him to a dangerous pitch. But his influence continued predominant. An attempt, instigated by the Lacedæmonians, was made to sacrifice him on account of a taint of sacrilege in his family (see Alcmæon); but the attempt failed. His enemies tried to wound him through his friends. Anaxagoras, the philosopher, was indicted for impiety and banished. Aspasia was included in the same charge, but the pathetic eloquence of Pericles moved the dicastery to acquit her. Scandals were propagated with intent to sully his character in connection with this remarkable woman of genius. (See Aspasia.) But the machinations of his enemies were futile. They had Phidias indicted for embezzlement, but here again they were foiled. A charge of impiety followed; and in this they were too successful. The great sculptor was found to have introduced in his statue of Athena the portraits of himself and of Pericles among the figures on the shield of the goddess. But against Pericles himself, at whom in reality all these shafts seem to have been aimed, the malice of his enemies failed, and he continued, with one brief interruption, the idol of Athens down to the day of his death. He was bitterly denounced for his defensive policy in the first campaign of the Peloponnesian war; but his power and influence were too solidly established to be quickly overthrown. When in the second campaign the Peloponnesians reappeared in Attica, the plague began to rage at Athens. The people saw their lands laid waste by an enemy and their crowded city desolated by pestilence. Rage and despair seized them, and now at length they turned upon Pericles. Still Pericles stood firm. He sought to divert the public mind by a foreign naval expedition; and he himself took command of a fleet and devastated the coast of Peloponnesus. Returning, he found the public mind yet more incensed against him. He was charged with peculation, the object of his enemies being to make him ineligible for the office of general. The charge was maintained, and he was fined. But a reaction soon followed, and he was reëlected general, his enemies were foiled, and he regained all his popularity. More terrible calamities awaited him, the pestilence stripping him of many of his personal and political friends, and finally of his sister and his two legitimate sons, Xanthus and Paralus. But the Athenians loved him as a father; and to alleviate his woe, they legitimized a son named Pericles whom Aspasia had borne him, though it was their great leader himself who had proposed the law which excluded from citizenship all who were not Athenians on both the father's and the mother's side. Pericles fell a victim to the prevailing epidemic about a year afterward. When dying, he reminded those who stood around his bed, recounting his deeds, of one circumstance they had failed to notice, but which he considered more glorious than any service they had enumerated, namely, "that not a citizen of Athens had been obliged to put on mourning on his account."—Pericles was reserved, appearing in public but little, and yet he continued the idol of the people for 40 years of public administration, 25 years with others, and 15 alone. Plato extols his "majestic intelligence." Thucydides, his contemporary, says of him: "Pericles, powerful from dignity of character as well as from wisdom, and conspicuously above the least tinge of corruption, held back the people with a free hand, and was their real leader instead of being led by them. For, not being a seeker of power from unworthy sources, he did not speak with any view to present favor, but had sufficient sense of dignity to contradict them on occasion, even braving their displeasure." Eupolis, the comic poet, declares that "persuasion itself sat upon his lips." Aristophanes describes his eloquence as producing on the social elements the same effects that thunder and lightning produce on the atmosphere.

PÉRIER, Casimir, a French banker and statesman, born in Grenoble, Oct. 12, 1777, died in Paris, May 16, 1832. He was studying at a college of the Oratorians in Lyons at the outbreak of the revolution, when he rejoined his family at Paris. Having been drafted into the army, he served in the corps of engineers during the campaign of 1799-1800 in Italy. In 1801, on the death of his father, regent of the bank of France, he returned to Paris, and in partnership with his brother Scipion established a banking house. He was elected to the chamber of deputies, where he acted with the opposition, but saw with displeasure the revolution of July, 1830. He was the last minister appointed by Charles X., who hoped to retrieve his fortunes through his old opponent's popularity; but it was too late, and Périer was made one of a provisional committee of government. The revolution being completed, he was elected (Aug. 3) president of the chamber of deputies, which post he left to enter the cabinet as minister without a special department, but resumed it when Laffitte was made premier. He succeeded the latter, March 13, 1831, taking the department of the interior. He secured the independence of Belgium by sending a French army there in 1831 to oppose the invasion of the Dutch; ordered a French fleet to the mouth of the Tagus to assist in the overthrow of Dom Miguel; and occupied Ancona to check the progress of the Austrians in Italy. But at home the insurrectionary attempts of the legitimists or the republicans, the formidable revolt of the silk workers at Lyons, the indignant feeling of the people on hearing of the fall of Warsaw, and the growing spirit of liberalism, were difficulties with which he found himself unable to cope. Nevertheless, he devoted himself to his task to the last. In March, 1832, when the cholera broke out in Paris, he devised excellent measures to check its progress. He himself, in company with the duke of Orleans, visited the patients in the Hôtel Dieu, April 1. Five days later he was attacked by the disease, which at first appeared of a mild form, but soon resulted fatally. His funeral was attended by an immense concourse of people, and a monument was erected in his honor by public subscription in the cemetery of Père la Chaise.

PERIGEE (Gr. περι, about, and γη, earth), the opposite of apogee, and, as commonly understood, that point of the orbit of the moon where she is nearest the earth. The term is also sometimes used to denote that point of the orbit of the earth where it is nearest the sun; the sun is then said to be in perigee. It also signifies the least distance of a planetary body from the earth.

PERIHELION (Gr. περι, about, and ἡλιος, sun), that point of the orbit of a planet or a comet where it is nearest the sun. The distance of this point from the sun is called the perihelion distance of the body. It is opposed to aphelion.

PERIM, or Meyun, an island in the strait of Bab-el-Mandeb, in lat. 12° 39' N., long. 43° 25' E. It is 3½ m. long and 2½ m. broad, and divides the entrance of the Red sea into two channels called respectively the Great and Little straits. The former, between Perim and the coast of Africa, is 13 m. broad; and the latter, formed by the island and Cape Bab-el-Mandeb, on the coast of Arabia, is 1¾ m. Both straits are free from hidden dangers, but the little one is generally used by vessels passing to or from the Red sea. The island is a bare black rock, almost destitute of vegetation, and without water. On the S. W. side there is an excellent harbor about 1½ m. long and nearly ¾ m. broad, with a depth of 7 fathoms. As Perim commands the entrance to the Red sea, it has been twice occupied by the British. The first time was in 1799, when the French army was in Egypt, but the island was abandoned in 1801. Latterly the projected Suez canal has again alarmed the English for the safety of their Indian possessions, and they have once more established themselves on Perim. In Feb. 1857, it was formally taken possession of, and fortifications which command the little passage have been erected.

PERIODICAL LITERATURE, as the term is usually applied, comprises those serial publications the principal object of which is not the conveyance of news, but the circulation of interesting essays, tales, poems, and useful information of a literary, scientific, or artistic character. Periodicals are, furthermore, generally distinguished from newspapers by the greater care and reflection commonly bestowed upon their articles, and by their shape, which is always such that the numbers may be easily and conveniently bound and preserved in the form of books. Periodical literature embraces two classes of publications, the first devoted to literature or criticism, and the second to the sciences, the arts, or to special branches of knowledge. A few, however, present characteristics which would place them in both of these divisions.—The extension of knowledge and the multiplication of books rendered it impossible for the scholar to inform himself of the progress of learning in various countries, or to purchase and peruse more than a small portion of the works issued from the press; hence the necessity for critical journals. This literary want was first met in France. In Jan. 1665, Denis de Sallo, assuming the name of the sieur de Hédouville, issued at Paris the first number of the *Journal des savants.* He retired from the editorship in March, when 13 weekly numbers had been printed, in consequence of complaints made by the papal nuncio of the Gallican spirit displayed in some of the articles, and was succeeded by the abbé Jean Gallois, under whose supervision the journal was published at irregular intervals until 1672. Its publication was resumed by the abbé J. P. de la Roque in 1675, who was followed by L. Cousin in 1687. In 1701 it was placed under the protection of the chancellor of France, and a commission of learned men appointed to conduct it. It was interrupted by the revolution at the close of 1792, and an effort to revive it in 1797 was only so far successful that a volume of 394 pages was published; it was, however, permanently reëstablished in 1816, and still continues, and is conspicuous for its learning and candor. As the *Journal des savants* did not pay much regard to polite or amusing literature, J. Doneau de Visé founded in 1672 the second literary periodical in France, the *Mercure galant,* which gave reviews of poetry and the drama. Its title was changed in 1717 to the *Mercure de France,* and it was conducted with ability by Marmontel and others until 1818. It has since been revived for brief periods as the *Minerve Française* (1818–'20) and the *Mercure du XIX*^e^ *siècle.* In 1701 a society of Jesuits at Trévoux began the *Mémoires pour servir à l'histoire des sciences et des beaux-arts,* more commonly known as the *Mémoires de Trévoux.* It was characterized by the excellence of its critical judgments, and by the zeal with which it combated anti-Jesuitical opinions; it lasted until 1767. The other noteworthy literary journals of France in the last century were the *Année littéraire* (1754–'91) of Fréron; the *Décade* (afterward *Revue*) *philosophique* (1794–1807), by Ginguené; and the *Magasin encyclopédique* (1795), by Millin, the second series of which was styled *Annales encyclopédiques,* and the third *Revue encyclopédique.* It was suspended in 1832, when it was succeeded by the *Revue Française et étrangère,* by Jullien, of which only a few volumes were issued; and a second attempt by Didot to reëstablish it in 1846 as the *Nouvelle revue encyclopédique* was equally unsuccessful. In the present century the *Revue Française* (1828–'30 and 1837–'9), by Guizot, the *Revue de Paris* (1829–'46), the *Revue indépendante,* and many more have appeared and been discontinued. But the *Revue des deux mondes,* commenced in 1829, among whose most frequent contributors have been Ste. Beuve, Planche, Chasles, Rémusat, and De Broglie, has been marked by an ability which has made it permanent and placed it at the head of French critical serials. A rival publication, the *Revue contemporaine* (1852), with which has been united the *Athénéum Français,* is ably conducted by Calonne. The *Revue Britannique* (1825), edited by Saulnier and Pichot, and filled with translations from the periodical journals of Great Britain and the United States; the *Revue Germanique,* devoted to German literature; the *Revue des races Latines* (1857), appropriated to the arts and letters of those nations having a Latin origin; and the *Revue Européenne* (1859), are the other existing French reviews of note. To the admission of poetry and tales into the reviews, and to the publication by almost every newspaper of a literary *feuilleton,* must be ascribed the almost total want in France of serials exactly corresponding to the English magazines. A few only of the most popular kind, like the *Magasin pittoresque* (1832), exist.—England seems, with the exception of Italy, to have been the first country to imitate the example of France. But the "Weekly Memorials for the Ingenious," the earliest issue of which is dated in Jan. 1681–'2, lasted but a year, and some of its articles were translations from the *Journal des savants.* The "Universal Historical Bibliothéque" began in Jan. 1686, and expired in March. The "History of Learning" (1691, and again 1694), and the "Memoirs for the Ingenious" (1694), were also of brief duration; but the "History of the Works of the Learned" (1699–1711) was more successful, though the works reviewed are chiefly continental. A learned French Protestant refugee, Michel de la Roche, edited in London the "Memoirs of Literature" (1709–'14), and afterward in Holland the *Bibliothèque Angloise* (1717–'27) and the *Mémoires littéraires de la Grande-Bretagne* (1720–'24); but his "Memoirs of Literature" was recommenced in England in 1725. In 1728 the title was changed to the "Present State of the Republick of Letters," and Andrew Reid assumed the editorship. It underwent another transformation in 1737, becoming the "History of the Works of the Learned," which was continued until 1743. Its place was then to some extent supplied by the "Literary Journal" (Dublin, 1744–'9), the earliest publication of the kind in Ireland. Since the middle of the 18th century it has been generally customary in English literature to apply the word review to those serial publications whose province is criticism, magazine to those whose pages are filled with miscellaneous and entertaining reading, and journal to periodicals of the scientific kind. The earliest of the first named class was the "Monthly Review" (1749–1844), established by Griffiths, who continued to conduct it for more than half a century. It was followed within the next 50 years by the "Critical Review" (1756–1817), founded by A. Hamilton and supported by the contributions of Smollett, J. Robertson, and other writers; the "London Review" (1775–'80), succeeded by the "New Review" (1781–'96) of Maty, and incorporated in 1797 with the

"Analytical Review" (1788-'99), which was driven from the field by the "Anti-Jacobin Review and Magazine" (1798-1821), and the "British Critic" (1793-1843), edited at first by Nares and Beloe, who advocated the principles of the English high church party. At the beginning of the 19th century the "Edinburgh Review" (1802), by the style and critical ability of its articles, at once elevated the standard of this class of serial literature. (See EDINBURGH REVIEW.) It was a vigorous defender of whig policy, and soon had a formidable rival in the tory "Quarterly Review" (1809) of London, successively edited by Gifford, J. T. Coleridge, and Lockhart, and numbering among its contributors Scott, Southey, and Croker. The "Westminster Review" (1824), styled for a period the "London and Westminster Review," was started by Bentham and other utilitarians, and as the organ of the radicals in politics has maintained a high position under the direction of Bowring, Mill, and Hickson. The "Eclectic Review" (1805), in which papers by Adam Clarke, Robert Hall, and John Foster appeared, was evangelical in religion and liberal in politics; the "Christian Observer" (1802), edited by Z. Macaulay, C. Wilks, and others, is the organ of the moderate church party; and the "Dublin Review" (1836) was brought into existence by O'Connell and his friends as the representative of Catholic literature. Many able reviews have within a few years ceased to exist. Such are the "Foreign Quarterly Review" (1827-'46), which occupied itself, under the editorship of Gillies and Fraser, with foreign literature; the "British Review" (1811-'25); the "Retrospective Review" (1820-'26, and again 1853), which gave reviews of old books; and the "Irish Review" (1857). Their places have been filled by the "British Quarterly Review" (1845), successor to the "British and Foreign Review" (1835-'45), the "North British Review" (1844), the "New Quarterly Review" (1852), the "Scottish Review" (1853), the "London Review" (1853), the "National Review" (1855), and a few others. The reviews are generally printed quarterly, but the "Saturday Review" (1856), which combines political articles with critical notices of new publications, is a successful weekly; while the "Literary Gazette" (1817), "Athenæum" (1829), "Critic" (1851), and "London Review" (1860) are also hebdomadal journals of criticism, giving a portion of their space to literary intelligence.—The "Tatler" (1709-'10) and "Spectator" (1711-'12 and '14) traced out a new path in literature, in which many imitators, not only in England, but all over the continent, hastened to follow. Of the multitude of similar English publications, the "Rambler" (1750-'52) of Johnson was the most famous. The pleasing and popular papers of Addison and Steele created a large class of readers who were content with a less amount of erudition than was displayed in the pages of the critical periodicals, and whose chief desire was entertainment, or instruction in the garb of entertainment. Out of the want felt by this new public grew the English magazines, the earliest of which was the "Gentleman's Magazine," commenced in London by Cave in 1731, and continued after his death by Henry and Nichols, the editors assuming the pseudonymous appellation of Sylvanus Urban. Johnson and other eminent writers of the 18th century contributed to it; beside sketches and essays, it published for a time the proceedings of parliament; and it contains obituaries and much other historical matter, which has been made easily accessible to the investigator by the publication of 5 index volumes. It is still continued, but for many years its pages have been almost wholly devoted to history and archæology. Cave had a host of followers. The "London Magazine" (1732-'84), the "Royal Magazine" (1759-'71), the "Oxford Magazine" (1768-'82), the "European Magazine" (1782-1826), the "Scots Magazine" (1739-1817), the earliest in Scotland, and the "Monthly Magazine" (1796-1830), supported by the efforts of Priestley, Godwin, and others, were among the chief ones which originated in the 18th century. "Blackwood's Edinburgh Magazine" (1817) is of a higher order than any of its predecessors, and has never been excelled (see BLACKWOOD'S MAGAZINE); but the "New Monthly Magazine" (1814), edited in turn by Campbell, Hood, Bulwer-Lytton, and Ainsworth, "Fraser's Magazine" (1830), and the "Dublin University Magazine" (1832), have approached it in excellence. "Tait's Edinburgh Magazine," "Sharpe's London Magazine," "Bentley's Miscellany," and the "United Service Journal," which is partly devoted to the military sciences, are of a lighter character. A new era in this sort of literature has been introduced by the shilling magazines, of which "Macmillan's Magazine" (1859), the "Cornhill Magazine" (1860), edited by Thackeray, and "Temple Bar" (1860), by Sala, are the best, the last two having attained an enormous circulation. The "St. James's Magazine" is the newest of this class, having been established in April, 1861. The weekly magazines began in 1832 with the "Penny Magazine" (1832-'45) of Knight, and "Chambers's Journal." The former was not only very successful, owing to its illustrations and its cheapness, but it led to a crowd of imitations both in Europe and America. This popular class of journals, including the "Saturday Magazine" and "Family Herald," has of late been greatly improved, and far better examples of the kind are "Howitt's Journal" (1847-'9), "Household Words" (1850-'59), conducted by Dickens, "All the Year Round" (1859), by the same editor, "Once a Week" (1859), the "Leisure Hour" (1851), and many others. A peculiar department in periodical literature has been marked out and filled since 1849 by "Notes and Queries," which forms a medium of intercommunication for men of letters, and a repository for brief notes on curious topics in the various branches of literature. —In Germany a translation of the *Journal des savants* appeared at an early day, but in 1682 an original work, the *Acta Eruditorum*, was founded by two private learned societies at Leipsic. It was less brilliant, although by no means less erudite, than its French prototype; but being written in the Latin language, sternly orthodox in its Lutheran opinions, and governed by no systematic code of criticism or philosophy, it failed to exert the influence or attain the success of the Paris periodical. Supported by the contributions of men like Leibnitz, Seckendorf, and Cellarius, it continued until 1776. The first literary serials in the German language were written in the form of dialogues; they were the *Monatsgespräche* (1688–'9) of Thomasius, and the *Monatliche Unterredungen* (1689–'98) of Tenzel, who subsequently edited the *Curieuse Bibliothek* (1704–'7). The *Novellen aus der gelehrten und curieusen Welt* (1692) had but a brief existence, and the *Deutsche Acta Eruditorum* (1712–'56), an imitation of the Latin work, was the first really successful undertaking of the kind. Under the title of *Gelehrte Zeitung*, almost every large town had at some period during the 18th century its literary journal. Such, for instance, were established at Frankfort (1736–'86), Halle (1766–'92), Kiel (1771–'97), Gotha (1774–1804), Erfurt (1781–'96), and Erlangen (1790–'97). But more important were the *Neue Zeitung von gelehrten Sachen* (1715–'97), edited by Beck and others, and whose closing volumes are entitled *Literarische Denkwürdigkeiten;* the *Göttinger gelehrte Anzeigen*, begun in 1739 as the *Zeitungen von gelehrten Sachen*, whose editors, among others, have been Haller, Heyne, and Eichhorn, and which is still published; the *Allgemeine Deutsche Bibliothek* (1766–1806), founded by Nicolai; the *Briefe, die neueste Literatur betreffend* (1759–'65), in which Lessing, Mendelssohn, and Abbt took part; the so called *Bremer Beiträge*, through whose pages Gieseke, Zachariä, Gellert, Gärtner, and other critics exercised a powerful influence upon the German literary world; the *Allgemeine Literatur-Zeitung*, established by Bertuch at Jena in 1785, but removed by Schütz to Halle in 1804, and continued until 1848; and the *Jenaische allgemeine Literatur-Zeitung*, founded by Eichstädt at Jena upon the removal of the last named, and also suspended in 1848. In the last half century the *Leipziger Literatur-Zeitung* (1800–'34), the *Wiener Jahrbücher der Literatur* (1818–'48), *Hermes* (1819–'31), distinguished for its erudition, and the *Jahrbücher für wissenschaftliche Critik* (1827–'47) have ceased to appear. The leading existing critical authorities are the *Heidelberger Jahrbücher der Literatur* (1808); the *Repertorium der Deutschen und Ausländischen Literatur* of Gersdorf, a continuation of the *Repertorium der gesammten Literatur* (1834–'43); the *Deutsche Vierteljahrsschrift* (1838), modelled upon the English review; the *Gelehrte Anzeigen* of the Bavarian academy, and the above mentioned Göttingen periodical of the same name. Of a lighter and more popular tone are the *Blätter für literarische Unterhaltung* (1833), previously edited by Kotzebue as the *Literarisches Wochenblatt;* the *Deutsches Museum* (1852), by Prutz; the *Grenzboten* (1841), by Schmidt and Freytag; *Westermann's Monatshefte* (1855), and many more of the magazine kind. The *Illustrirtes Familien-Journal* of Leipsic is of the "Penny Magazine" school, and enjoys a very large circulation.—In 1668, three years after the appearance of Sallo's journal, the *Giornale de' letterati* was commenced at Rome by Nazzari, and published until 1679. Under the same title literary periodicals were afterward issued at Parma (1686–'90) by Roberti and Bacchini, at Venice (1710–'33) by the brothers Zeno, at Florence (1742), and finally at Pisa in 1771, which last has been continued, with the exception of a brief period (1797–1801), down to our own time. The *Biblioteca volante* (1676–1718, and 1733–'47), commenced by Cinelli and continued by Sancassani, was of a less solid character; but the *Novelle letterarie*, published for several years subsequent to 1740, and edited in part by Lami, was marked by much erudition. Distinguished at a later period have been the *Biblioteca Italiana* (1816–'40) of Milan, conducted at first by Acerbi; the *Antologia* (1821–'32) of Florence, under the direction of a society of scholars; the *Giornale Arcadico* (1819) of Rome, begun by Odescalchi; the *Giornale enciclopedico* 1806) of Naples, which was followed in that city by the *Progresso delle scienze* (1833–'48), and since by the *Museo di scienze e letteratura;* and several minor ones, like the *Poligrafo* (1811), and *Magazzino pittoresco*, and the popular *Album* (1824) of Rome. The chief critical serials at present are the *Rivista contemporanea* (1852) of Turin, resembling in style and appearance the French *Revue des deux mondes*, and the *Politecnico* (1839) of Milan, which was suppressed in 1844 and revived in 1859.—Spain was represented in periodical literature during the 18th century by the *Diario de los literatos* (1737–'47); the *Pensador* (1762), one of the "Spectator" school, and chiefly written by Clavijo; the *Seminario erudito* (1775–'91), by Balladeres, noted for its publication of rare and important literary manuscripts; the *Memorial literario* (1784–1807); and the *Variedades*, which acquired a considerable reputation under the management of Quintana. The *Cronica cientifica y literaria* (1824), by Mora, subsequently became a political sheet. The *Censor* (1820), by Lista, Hermosilla, and Miñano, was for some years the best periodical which Spain had seen; this was finally superseded by the *Revista Española* (1831), which successively changed its title to *Revista Europea* and *Revista de Madrid*. Later are the *Cartas Españolas* (1831), the *Antologia Española* (1848), the *Revista Hispano-Americana* (1848), edited by Mora for a brief period only, the *Revista de España*, the *Seminario pintoresco*, and the *Revista de* *ambos mundos.*—The *Jornal de Coimbra* in the earlier part of this century was the first, and for a long time the only, literary organ of which Portugal could boast. In 1837, however, the *Panorama* was founded, and still circulates largely both in Spain and Brazil; and in 1842 the very excellent *Revista universal Lisbonense* was established by Castilho, but is now edited by Ribeiro de Sá. Other publications of the literary class are the *Jornal da sociedade dos amigos das letteras* and the *Bibliophilo.*—In Holland two celebrated men, eminently qualified for the pursuit, entered upon the career of literary journalism in the latter part of the 17th century. The *Mercure savant* (1684) of Desbordes at Amsterdam was a feeble production; but Bayle in the same year began his *Nouvelles de la république des lettres*, which was continued with great success until 1718. He speedily found a rival in Le Clerc, who undertook in 1686 the first of the three famous series of reviews to which he is indebted for so much of his reputation. These were the *Bibliothèque universelle et historique* (1686–'93), the *Bibliothèque choisie* (1703–'13), and the *Bibliothèque ancienne et moderne* (1714–'27); they are characterized by fulness, variety, and judicious analysis and selection. The first periodical in the vernacular was the *Boekzaal van Europa* (1692–1708, and 1715–'48), by Rabus and Sewel, which was excelled by the *Republijk der Geleerden* (1710–'48). J. van Effen, imitating the English essayist, produced his *Hollandsche Spectator* (1731–'5) with marked success; but a new era in criticism was introduced in 1761 by the *Vaderlandsche Letteroefeningen*, which still continues. The *Algemeene Konst- en Letterbode* (1788) maintained for many years a high rank, but now exerts little influence. The *Recensent* (1803), lately superseded by the *Nieuwe Recensent*, has proved itself a powerful rival to the *Letteroefeningen*. Other existing periodicals are the *Nederlandsche Museum* (1835), the *Tijdstroom* (1859), and the *Navorscher* on the plan of the London "Notes and Queries."—The *Esprit des journaux* (1772–1818) is a Belgian literary miscellany of considerable value; but it was not until the separation from Holland that the periodicals of Belgium began to be of much interest. The *Messager des sciences*, edited for many years by St. Genois, is frequently quoted, while the chief issues in the Flemish tongue have been the *Nederduitsche Letteroefeningen* (1834), by Blommaert; the *Belgisch Museum* (1836–'46), by the well known scholar Willems; the *Kunst- en Letterblad* (1840–'43); the *Vlaemsche Rederyker* (1844), and one or two more popular miscellanies.—In Switzerland the *Bibliothèque Britannique* (1796–1815), and its more original successor the *Bibliothèque universelle* (1816), which is published in two parallel series, one scientific and the other literary, are widely circulated both at home and abroad. The *Revue Suisse* has been conducted with much success at Neufchâtel since 1837.—The earliest noteworthy literary journal of Denmark was the *Lærde Tidende* (1749–'65). Then came the *Minerva* (1785) of Rahbek, continued with a slight change of title until 1819; the *Danske Tilskuer* (1791–1808); the *Skandinavisk Museum* (1798–1803), revived as the *Litteratur Selskabs Skrifter* (1805–'32); and the *Lærde Efterretninger* (1799–1810), by Müller, ably continued by the same editor under the name of *Litteratur-Tidende* (1811–'36). Mölbech published the *Athene* (1813–'17) and other periodicals, one of which, the *Historisk Tidskrift* (1840), has survived him, and is now edited by Westergaard. The more modern journals are the *Tidskrift for Litteratur og Kritik* (1839–'42), now transformed into the quarterly *For Litteratur og Kritik* (1842); *Maanedskrift for Litteratur* (1829–'38); the *Nordisk Litteratur-Tidende* (1846); *Nord og Syd* (1848–'9), by Goldschmidt, revived in 1856, and now changed to the *Hjemme og Ude*; and the *Dansk Maanedskrift*, by Steenstrup, commenced in 1858. In 1854 the *Nordisk Universitets Tidskrift*, a well managed quarterly review, of which the numbers are alternately published in Swedish and Danish by the four Scandinavian universities of Copenhagen, Christiania, Upsal, and Lund, originated in the Danish capital.—The *Svenska Argus* (1732–'4), written by Dalin, a warm admirer of Addison, was the earliest notable addition made by Sweden to learned periodical literature. In 1742 Celsius founded the *Tidningar om den lärdas Arbeten*, which was afterward edited by Salvius and Gjörwell as the *Lärda Tidningar*; but the first comprehensive critical journal was the *Svenska Mercurius* (1755–'65) by Gjörwell. The *Vitterhets-Journal* (1777–'8), by Rudin and Ristell, scarcely deserves mention. The *Phosphoros* (1810–'13), by Atterbom and Palmblad, carried on by the latter as the *Svensk Literatur-Tidning* (1813–'24), and its adversary the *Iduna* (1811–'24), edited by a society styled *Göthiska Förbundet*, both wielded a powerful influence in the literary circles of Sweden, and originated two different schools of poetry and criticism. Among other periodicals may be mentioned *Polyfem* (1810–'12); *Svea* (1818–'32), noticeable for its elevated tone and clever reviews of foreign books; *Journal för Literaturen* (1809–'13), subsequently known as the *Allmänna Journalen* (1813–'23); *Skandia* (1833–'7); *Literatur-Föreningens Tidning* (1833–'6); and the *Literaturblad* (1838–'40). The best of a later date are the *Tidskrift för Literatur* (1850), by Malmström, and the *Nordisk Tidskrift*, by Solman (1852).—*Nor* (1840–'46), conducted by members of the Christiania university, and the *Norsk Tidskrift för Videnskab og Literatur*, established in 1847, and since edited by Lange, are the only especially prominent literary organs which have yet arisen in Norway. The periodicals published in the Icelandic language are not numerous. They comprise the *Sagnablöd* (1817–'26), edited by Finn Magnusson, and now issued under the name of *Skirnir* (1827); *Fjölnir* (1835–'45);

Ny Fjelagsrit (1841), a review edited chiefly by Jon Sigurdsson; and *Nordurfari* (1848–'9), by Gisli Brynjulfsson. In Finland the sole literary journal deserving of notice is the *Suomi*, which has been issued in the Swedish language since 1840.—The existing periodicals of Russia are more noted for their size than their number, a single issue sometimes containing 300 pages. Periodical literature in that country began with the *Yezhemyesyatchniya sotchineniya* ("Monthly Essays"), edited by Müller from 1755 to 1764. Soon afterward commenced Sumarakoff's "Industrious Bee" (1759), and Kheraskoff's "Leisure Hours" (1762). Superior to these, however, was the *Vyestnik Evropi* ("European Intelligencer"), founded in 1802 by the historian Karamsin, and subsequently (1808) edited by Zhukovsky. To this succeeded the *Ruskoy Vyestnik*, conducted from 1808 to 1820 by S. N. Glinka, then by Gretch and Polevoy, and which, after having been suspended for some years, was revived at Moscow in 1856 by Katkoff. One of the ablest publications was the *Sin otetchestva* ("Son of the Fatherland"), founded in 1812, with which was united in 1825 the *Severnoy Arkhiv* (1822), or "Northern Archives," at which time Bulgarin and Gretch became joint editors; the latter resigned it in 1839 into the hands of Massalsky, and a few years afterward it ceased to appear. The "Telegraph" of Moscow (1825–'35), by Polevoy, began a new era in Russian criticism; it was suppressed by the government, and its successor, Nadeshdin's "Telescope," speedily met with a similar fate. They were followed in the old capital of Russia by the *Moskvitanin* (1840), the organ of the Panslavic theories. The *Biblioteka dlya tchteniya* ("Library for Reading") owed its origin (1834) to Gretch, who was followed in the chair of editorship by Senkovsky; under the direction of Smirdin it is still one of the foremost periodicals of the country, although a portion of its contents consists of translations, chiefly from English works. The *Sovremennik* ("Contemporary"), founded by Pushkin in 1836, was afterward conducted by Pletneff; while the *Otetchestvennya zapiski* ("National Journal") was edited at first (1840) by Byedinsky, and then by Krajevsky, distinguishing itself under both by the zeal with which it opposed Panslavism. Outside of the country itself the *Archiv für die wissenschaftliche Kunde von Russland*, edited at Berlin by Erman since 1841, gives a valuable *résumé* of the labors of the Russian men of science and letters.—The *Dziennik Warszawski* ("Warsaw Journal"), founded by Mochnacki and Podczaszynski in 1823, has contained many excellent essays by such men of learning as Lelewel, Mickiewicz, and Brodzinski. An important periodical was edited by Lach Szyrma under the title of *Pamietnik Warszawski* ("Warsaw Memoirs"). The "Athenæum" was issued at the same place by Kraszewski, but expired at the end of 3 or 4 years; and a number of Polish literary serials have appeared at Wilna, Cracow, Posen, and Lemberg.—The principal literary periodical of Bohemia, the *Casopis Ceskmho Muzeum* ("Journal of the Bohemian Museum"), was begun in 1827 by the patriotic Palacky, edited from 1837 to 1842 by Schafarik, and since that time by Wocel. It has done much toward building up a vernacular literature.—In the south-Slavic lands, the *Danica Iliriyska* ("Illyrian Morning Star"), founded in 1835 by Gaj, lasted until the Hungarian struggle; and lately the *Glasnik Slovenski* ("Slavic Herald") has made its appearance at Klagenfurt.—Foremost in point of time among the serial issues of the Hungarian press was the *Magyar muzeum* (1788), started by Kazinczy, Szabó, and Bacsányi; but it soon expired, and Kazinczy for a while conducted the *Orpheus*. The *Tudományos gyüjtemény*, or "Literary Magazine," held from 1817 to 1841, under the editorship of Vörösmarty and others, the first place among Hungarian periodicals, but it had for a time a rival in the *Élet és literatura* ("Life and Literature"), originated in 1826 by Kölcsey and P. Szemere. The *Figyelmező*, or "Observer" (1837–'43), was an influential literary serial under the charge of Bajza, who in conjunction with Schedel also conducted the "Athenæum," an imitation of the London periodical of the same name, which enjoyed for a considerable time a deserved success. The *Erdélyi muzeum* ("Transylvanian Museum") of Döbrentei had only a brief existence, but the *Uj Magyar muzeum*, or "New Hungarian Museum," has during the last decennium been the principal critical journal of Hungary.—Ὁ Λογιος Ἑρμης ("The Learned Mercury"), the earliest periodical of modern Greece, was maintained by the contributions of Asopios and other prominent men. To it has succeeded the Ευρωπαικος Ερανιστης, or "European Contributor," established by Rangabé and others at Athens in 1840.—In India the issues of the periodical press are of course formed upon English models. The earliest one of a literary character was the "Calcutta Monthly Register" (1790), which lasted for some months. Of its successors the best known are the "Oriental Magazine and Indian Hurkaru," which began at Madras in 1819; the "Madras Miscellany;" the "Calcutta Review" (1844), a valuable existing quarterly; and the "Bombay Quarterly Review," which dates from 1855. At Singapore the "Journal of the Indian Archipelago" has been published since 1847, while the "Chinese Repository," begun by Morrison at Canton, was from 1832 to 1851 filled with valuable articles relating chiefly to the literature and history of the extreme East.—The periodicals of Spanish and Portuguese America have as yet hardly attained even a local success. Brazil did not possess a critical journal of the first class until Oliveira began in 1859 the *Revista Brasileira* at Rio Janeiro. Peru has nothing better or of a later date to show than the old *Mercurio Peruano* (1791–'5). The *Mercurio Chileno*, edited by Mora during the period of his exile from Spain, was a creditable production; and has been followed by one or two unsuccessful attempts to establish a permanent magazine in Chili. In Mexico the *Gaceta de literatura* of Ramirez (1788–'95) has scarcely been equalled since the establishment of the republic.—Reversing the rule which had prevailed in the old world, the United States, as was natural in a new country where scholars and institutions of learning were as yet few, had its journals of entertainment long before its journals of erudition appeared. The date of the first literary periodical is 1741. In that year Franklin issued the "General Magazine and Historical Chronicle" at Philadelphia, on the plan of the "Gentleman's Magazine;" but it existed only half a year, while the "American Magazine," begun in the same year and city by Webbe, was still less successful, two numbers only being published. The other issues of the kind prior to the revolution were mostly short-lived. They were the "American Magazine and Historical Chronicle" (Boston, Oct. 1743, to Dec. 1746); the "Boston Weekly Museum" (4 nos., 1743); the "Independent Reflector" (New York, 1752–'4), which numbered among its contributors Gov. Livingston and the Rev. A. Burr; the "New England Magazine" (Boston, 1758), which ceased after the appearance of a few parts; the "American Magazine" (Philadelphia, Oct. 1757, to Oct. 1758), published by Bradford; the "North American Magazine" (Woodbridge, N. J., 1758–'60), by S. Nevil; the "American Magazine" (Philadelphia, 1769), by Nicola; the "Royal American Magazine" (Boston, 1774–'5); and the "Pennsylvania Magazine" (Philadelphia, 1775), commenced with articles by Thomas Paine and others, but interrupted by the war. After the conclusion of peace and before the end of the century came the "Columbian Magazine" (Philadelphia, 1786–'9), edited at first by Carey, who abandoned it to undertake the "American Museum" (1787–'97), a compilation from the newspapers and other journals of the time, of much historical value; the "Massachusetts Magazine" (Boston, 1789–'96); the "New York Magazine" (1790–'97); the "Farmer's Museum" (Walpole, N. H., 1793), edited from 1796 until near the close of the century by Dennie; the "United States Magazine" (Philadelphia, 1796), by Brackenridge; the "American Universal Magazine" (Philadelphia, 1797); and the "Monthly Magazine and American Review" (New York, 1799–1800), founded by the novelist Brown, but carried on afterward as the "American Review and Literary Journal" (1801–'2). It would hardly be possible to give a complete list of the numerous literary miscellanies which have been undertaken since 1800 in the principal cities of the Union. A large majority of them never succeeded in obtaining any thing like success or permanence. Among them was the "Portfolio" (Philadelphia, 1801–'25), by Dennie, the first American periodical which was fortunate enough to reach an age of over 20 years; the "Literary Magazine" (Philadelphia, 1803–'8), by C. B. Brown; the "Monthly Anthology" (Boston, 1803–'11), containing articles by Tudor, Buckminster, J. Q. Adams, and G. Ticknor; the "Literary Miscellany" (Cambridge, 1804–'5); the "General Repository" (1812–'13), at the same place; the "Mirror of Taste" (Philadelphia, 1810–'11), by Carpenter, who paid much attention to dramatic matters; the "Monthly Register" (Charleston, 1805), the first southern periodical; "Literary Miscellany" (New York, 1811), by Baldwin; the "Analectic Magazine" (Philadelphia, 1813–'20), designed especially for officers in the navy, and edited in 1813–'14 by Irving; the "New York Weekly Museum" (1814–'17); the "Portico" (Baltimore, 1815–'19); Buckingham's "New England Magazine" (1831–'5); the "American Monthly Magazine" (New York, 1817–'18); the "Literary and Scientific Repository" (New York, 1820–'21); "Atkinson's Casket" (Philadelphia, 1821–'39), displaced at last by "Graham's Magazine," which from 1840 to 1850 was the best of its class in America; the "Atlantic Magazine" (New York, 1824–'5), by Sands, continued until 1827 as the "New York Review;" the "Southern Literary Gazette" (1825); the "New York Mirror" (1823), begun by Morris and Woodworth, the latter being succeeded by Fay, who gave place to Willis, from which time until 1842 Morris and Willis successfully conducted it; the "Illinois Monthly Magazine" (Vandalia, 1830–'32), the earliest publication of a literary character in the West, edited by J. Hall, who superseded it by the "Western Monthly Magazine" (Cincinnati, 1833–'6); the "American Monthly Magazine" (New York, 1833–'8), established by Herbert and Patterson, and subsequently edited by Park Benjamin; the "Gentleman's Magazine" (Philadelphia, 1837–'40), by W. E. Burton; the "Dial" (Boston, 1840–'44), edited during its first two years by Margaret Fuller, and afterward by R. W. Emerson, the organ of the school of New England transcendentalists; "Arcturus" (New York, 1840–'42), by C. Mathews and E. A. Duyckinck; the "Magnolia" (1842–'3); the "International Magazine" (New York, 1850–'52), under the editorial charge of R. W. Griswold; "Putnam's Monthly" (New York, 1853–'7), of a higher character, both in plan and execution, than any that had preceded it; and "Russell's Magazine" (Charleston, 1857–'8). All the early magazines drew largely from English sources, but in 1811–'12 appeared at Philadelphia the "Select Views of Literature," solely devoted to reprints from the foreign periodical press; it has been followed by the "Saturday Magazine" (Philadelphia, 1821), the "Museum of Foreign Literature" (Philadelphia, 1822–'39), the "Select Journal of Foreign Periodical Literature," edited by A. Norton and C. Folsom (Boston, 1833–'4), and by two existing publications, "Littell's Living Age" (Boston,

1844) and the "Eclectic Magazine" (New York, 1844). A multitude of magazines filled with light reading, and designed more particularly for circulation among the women of America, have been published, the earliest of which were the "Ladies' Magazine" (Philadelphia, 1799) and the "Lady's Weekly Miscellany" (New York, 1807–'8); later ones are the "Lowell Offering" (1841), chiefly written by female operatives in the New England factories; the "Ladies' Companion" (New York, 1820–'44); the "Columbian Magazine" (New York, 1844–'8); the "Union Magazine" (New York, 1847), by Mrs. Kirkland, afterward published at Philadelphia as "Sartain's Magazine;" "Arthur's Magazine" (Philadelphia); "Miss Leslie's Magazine" (Philadelphia); and the still issued "Godey's Lady's Book" and "Peterson's Magazine" of Philadelphia. Magazines for children appear to have originated with the "Young Misses' Magazine" (Brooklyn, 1806), and have been frequently published since under such titles as "Youth's Magazine," "Youth's Cabinet," "Parley's Magazine," and "Merry's Museum." The existing magazines of a higher order are the "Knickerbocker," founded by C. F. Hoffman at New York in 1832, and edited since 1834 by Louis Gaylord Clark; the "Southern Literary Messenger" (Richmond, 1835), edited for a brief period by Poe; "Harper's New Monthly Magazine" (New York, 1850), combining selections from foreign publications with a large amount of original matter, ably conducted from the outset, and having a circulation far beyond that ever attained by any similar publication; and the "Atlantic Monthly" (Boston, 1857), edited by J. R. Lowell, supported by original contributions from some of the foremost American and English novelists, essayists, and poets. Rather historical than literary have been the "American Register" (Philadelphia, 1806–'10), and periodicals of the same name by Walsh (Philadelphia, 1817) and by Stryker (Philadelphia and New York, 1848–'51), as well as the "American Quarterly Register" (Andover, 1829–'43), by Edwards. The "New England Historical and Genealogical Register" (Boston, 1852), by Drake, and "Historical Magazine" (New York, 1857), by Folsom, are also filled with American historical and biographical matter.—The review literature of the United States begins with the "American Review of History and Politics" (Philadelphia, 1811–'13), by Walsh; but the ablest and most permanent publication of this sort has been the "North American Review" (Boston, 1815), which has been successively edited by Tudor, E. T. Channing and R. H. Dana, Edward Everett, Sparks, A. H. Everett, Palfrey, Bowen, and Peabody, and has constantly maintained a high character both for style and critical ability. The "American Quarterly Review" (Philadelphia, 1827–'37); the "Southern Review" (Charleston, 1828–'32), by Elliott and Legaré; the "Western Review" (Cincinnati, 1828–'30), by Flint; the "New York Review" (1837–'42), established by Hawks, and subsequently edited by J. G. Cogswell and C. S. Henry; and the "Southern Quarterly Review" (Charleston, 1842–'52), were well conducted, but have been discontinued. The same fate has befallen the "Democratic Review" (New York, 1838–'52), afterward the "United States Review" (1853–'5), and subsequently revived by Florence and Lawrence as the "National Democratic Quarterly Review;" the "American Whig Review" (New York, 1845–'52), by Colton and Whelpley; the "Massachusetts Quarterly Review" (Boston, 1847–'50), by T. Parker; and the "New York Quarterly Review" (1852–'3). The "New Englander" began at New Haven in 1843, and the "National Quarterly Review" at New York in 1860. A large number of reviews, organs of the various religious bodies, are to be regarded partly as critical and partly as theological journals. Such are the "Christian Examiner" (Boston, 1824), a supporter of Massachusetts Unitarianism, edited at various times by Palfrey, Jenks, Walker, Greenwood, W. Ware, Ellis, Putnam, Hedge, and Hale, and which grew out of the "Christian Disciple" (1813–'24), conducted chiefly in the first instance by Noah Worcester; the "Biblical Repository and Bibliotheca Sacra," published under that name since 1851, formed by the union of the "Biblical Repository" (which originated in 1831, and with which was joined the "American Quarterly Observer," 1833–'5) of Edwards with the "Bibliotheca Sacra" of Robinson; the "Methodist Quarterly Review," commenced as the "Methodist Magazine" (1818); the "Biblical Repertory and Princeton Review," begun by Hodge in 1825 as the organ of the Westminster Calvinists; the "Christian Review" (1836), advocating in religious matters the principles of the Baptists; the "Protestant Episcopal Quarterly Review" (1854), and the "American Church Review" (New Haven, 1848); the "Universalist Quarterly" (Boston, 1843), by G. H. Emerson; the "Presbyterian Quarterly Review" (Philadelphia, 1852), by Wallace; the "Evangelical Review" (Gettysburg, Penn.), by Krauth and others; the "Universalist Quarterly Review" (Boston, 1844); and "Brownson's Quarterly Review," begun as the "Boston Quarterly Review" (1838), and since 1844 maintaining Roman Catholic opinions. Many of the colleges have individually published literary journals, of which the "Yale Literary Magazine" (1836) is the best known; but in 1860 several of the higher institutions of education in conjunction established the "University Quarterly Review." Minor critical journals have been the "Literary Review" (New York, 1822–'4), followed by Bryant's "New York Review and Athenæum Magazine" (1825), and its successor, the "United States Review and Literary Gazette" (1826–'7); and two or three periodicals in imitation of the London literary weeklies have been attempted, such as the "New York Literary Gazette" (1834-'5 and 1839), the "Literary World" (New York, 1847-'53), edited by Hoffman and the Duyckincks, "Norton's Literary Gazette" (New York, 1854-'5), and the "Criterion" (New York, 1855-'6).—Journals devoted to the sciences and the arts, or to particular departments of human knowledge, began to be published in the latter years of the 17th century, but were not numerous until the beginning of the 19th, since which they have multiplied with wonderful rapidity, until there is now scarcely any subject of interest, or which can be made an object of investigation, which has not its periodical organs. The "Philosophical Transactions" (London, 1665) and the *Miscellanea Curiosa* (1670) of Germany may be regarded as the first serials devoted to the natural and philosophical sciences; and, indeed, a liberal definition of the term scientific periodical would embrace the whole of those works issued, sometimes irregularly, sometimes at stated intervals, by the learned societies of Europe and America, and generally known as "Transactions." The first theological journal was styled *Das Alte und Neue aus dem Schatz theologischer Wissenschaften*, founded in Germany by Löscher in 1701; in America the earliest publications of the kind were the "Christian History" (Boston, 1743-'5) and the "Royal Spiritual Magazine" (1771). The first serial in connection with jurisprudence was the *Journal du palais*, established by Guéret and Blondeau at Paris in 1672. At the same place in 1683, the abbé de la Roque had already begun the earliest specimen of a medical periodical, the *Journal de médecine*. Philology was early represented by the *Aurora Philologica* of Boysen (Halle, 1715), and Germany has continued to be, above all other countries, the seat of journals devoted to linguistics. Journals of mechanical science seem to have originated in England, and the British publications of that class greatly excelled until within a few years those of the continent; but Germany within the last quarter of a century has possessed serials devoted to the interests of almost every trade and profession. Systematic periodicals, embracing the mathematical, natural, and physical sciences, sprang into existence about the close of the last century almost simultaneously in France and Germany, and have in general been both better conducted and more successful than those of a corresponding class in England. Agricultural periodicals have been especially objects of attention in France and America, while those of England and Germany are in general of less value and interest. Every civilized country now has its journals of theology, jurisprudence, medicine, the natural sciences, the mechanical sciences, and agriculture, while in some many other specialities are represented. Few, however, except those in French, German, and English, are of general interest beyond the confines of the languages in which they are written. The following list, therefore, is limited to those tongues; it gives the titles, place of publication, and date of establishment of the more prominent scientific and special periodicals now (1861) published:

AGRICULTURAL SCIENCES.

Annales de l'Agriculture Française. Paris, 1798.
Journal des Haras. Paris, 1828.
Journal d'Agriculture pratique. By Barral. Paris, 1837.
Journal des Cultivateurs. Paris, 1858.
Zeitschrift für Deutsche Landwirthe. By Stöckhardt. Leipsic, 1850.
Neue landwirthschaftliche Zeitung. By Gumprecht. Glogau, 1851.
Journal of Agriculture. Edinburgh, 1843.
Journal of the Agricultural Society. London, 1840.
Farmer's Magazine. London, 1833.
Country Gentleman. Albany, 1852.
Cultivator. New York, 1844.
Working Farmer. By Mapes. New York, 1849.
American Agriculturist. New York, 1842.
Horticulteur Français. Paris, 1851.
Flore des Serres. By Decaisne and Van Houtte. Ghent, 1845.
Magazin für Garten- und Blumenkunde. By Neubert. Stuttgart, 1858.
Horticulturist. Established by Downing, now edited by Mead. New York, 1846.
Gardener's Monthly. Philadelphia, 1859.
Magazine of Horticulture. By Hovey. Boston, 1835.

ARCHÆOLOGY.

Annales Archéologiques. By Didron. Paris, 1844.
Revue Numismatique. By Witte and Longpérier. Paris, 1836.
Zeitschrift für Münz-, Siegel- und Wappenkunde. Berlin, 1859.
Archæological Journal. By the Archæological Institute. London, 1844.

ARCHITECTURE AND ENGINEERING.

Revue générale de l'Architecture. By Daly. Paris, 1840.
Annales des Ponts et Chaussées. Paris, 1831.
Annales des Travaux publiques de Belgique. Brussels, 1843.
Zeitschrift für das Bauwesen. Continuation of Crelle's Journal für die Baukunst, now conducted by Erbkam. Berlin, 1829.
Zeitschrift für praktische Baukunst. By Knoblauch. Berlin, 1841.
Civil-Ingenieur. By Bornemann. Freiberg, 1848.
Civil Engineer and Architect's Journal. London, 1837.
Builder. London, 1842.
Architect's and Mechanic's Journal. New York, 1859.

ART.

L'Artiste. Paris, 1831.
Gazette des Beaux-Arts. By Le Blanc. Paris, 1859.
Düsseldorfer Künstler-Album. By Königswinter. Düsseldorf, 1851.
Art Journal. By Hall. London, 1839.
Crayon. By Durand. New York, 1855.

ASTRONOMY.

Astronomische Nachrichten. Founded by Schumacher, since edited by Peters. Altona, 1823.
Wochenschrift für Astronomie. Begun as Astronomische Unterhaltungen, by Heis. Halle, 1847.
Astronomical Journal. By Gould. Cambridge, Mass., 1851.

BIBLIOGRAPHY.

Bibliographie de la France. Paris, 1798.
Bulletin du Bibliophile. By Techener. Paris, 1834.
Bulletin du Bibliophile Belge. Founded by Reiffenberg, now conducted by Scheler. Brussels, 1844.
Serapeum. By Naumann. Leipsic, 1840.
Anzeiger für Bibliographie. By Petzholdt. Halle, 1840.
Literarisches Centralblatt. By Zarncke. Leipsic, 1850.
Publishers' Circular. London, 1838.
The Bookseller. London, 1858.
American Publishers' Circular. New York, 1855.

CHEMISTRY AND PHYSICS.

Annales de Chimie et de Physique. Formerly edited by Gay-Lussac and Arago, now by Chevreul, Pélouze, Lavoisier, and others. Paris, 1789.
Annalen der Physik und Chemie. By Poggendorff. Leipsic, 1824.
Journal für praktische Chemie. By Erdmann and Werther. Leipsic, 1828.
Annalen der Chemie und Pharmacie. By Wöhler, Liebig, und Kopp. Leipsic, 1832.
Chemisches Centralblatt. By Knop. Leipsic, 1850.
Quarterly Journal of the Chemical Society. London, 1849.
Chemical News. London, 1859.

CHESS.

La Régence. By Journoud. Paris, 1860.
Schachzeitung. By Lange. Leipsic, 1846.

Chess Player's Chronicle. London, 1841.
Chess Monthly. New York, 1857.

COMMERCE AND FINANCE.

Journal des Banquiers. By Le Hir. Paris, 1847.
Journal des Assurances. Paris, 1850.
Monde Commerciel. Paris, 1860.
Preussiches Handelsarchiv. By Saint-Pierre and Moser. Berlin, 1847.
Banker's Magazine. London, 1848.
Economist. London, 1843.
Assurance Magazine. London, 1851.
Merchants' Magazine. Established by Hunt. New York, 1839.
De Bow's Commercial Review. New Orleans, 1846.
Bankers' Magazine. New York, 1847.
United States Insurance Gazette and Magazine. By Currie. New York, 1855.

EDUCATION.

Journal de l'Éducation populaire. Paris, 1815.
Revue de l'Instruction publique. Paris, 1841.
Pädagogisches Jahrbuch. By Diesterweg. Leipsic, 1851.
Jahrbücher für Philologie und Pädagogik. Founded by Jahn, edited now by Dietsch and Fleckeisen. Leipsic, 1831.
Repertorium der pädagogischen Journalistik. By Heindl. Munich, 1846.
English Journal of Education. London, 1841.
Journal of Education for Upper Canada. Toronto, 1848.
American Journal of Education. By Barnard. Hartford, 1856.
Instituteur des Aveugles. By Guadet. Paris, 1856.
American Annals of the Deaf and Dumb. Hartford, 1849.

FREE MASONRY.

Franc-Maçon. Paris, 1852.
Bauhütte. By Findel. Leipsic, 1858.
Free Masons' Quarterly Review. London, 1834.
Free Masons' Monthly Magazine. Boston, 1841.

GEOGRAPHY.

Nouvelles Annales des Voyages. By Malte-Brun. (Published by the elder Malte-Brun as the Annales des Voyages from 1808 to 1814.) Paris, 1816.
Bulletin de la Société de Géographie. By Maury and Malte-Brun. Paris, 1821.
Ausland. By Peschel. Stuttgart, 1828.
Zeitschrift für allgemeine Erdkunde. By Neumann. Berlin, 1858.
Geographische Mittheilungen. By Petermann. Gotha, 1854.
Journal of the Royal Geographical Society. London, 1831.
All Round the World. By W. F. Ainsworth. London, 1860.

INDUSTRIAL AND MECHANICAL SCIENCES.

Journal de l'École polytechnique. Paris, 1795.
Bulletin de la Société d'Encouragement pour l'Industrie. Paris, 1802.
Technologiste. Paris, 1837.
Revue des Sciences. (Formerly the Mémorial Industriel.) Paris, 1849.
Génie Industriel. By Armengaud. Paris, 1850.
Polytechnisches Journal. By Dingler. Stuttgart, 1820.
Polytechnisches Centralblatt. By Schnedermann and Böttcher. Leipsic, 1838.
Deutsche Gewerbe-Zeitung. By Wieck. Leipsic, 1835.
Repertory of Patent Inventions. London, 1794.
Journal of Arts and Sciences. By Newton. London, 1820.
Mechanics' Magazine. London, 1823.
Practical Mechanic's Journal. Glasgow, 1842.
Artisan. London, 1842.
Journal of the Franklin Institute. Philadelphia, 1821.
Scientific American. New York, 1844.

JURISPRUDENCE.

Journal du Palais. Paris, 1794.
Recueil général des Lois et Arrêts. Paris, 1800.
Journal du Droit criminel. Paris, 1828.
Journal de Procédure. Paris, 1834.
Revue critique de Législation. By Troplong and Wolowski. Paris, 1851.
Kritische Zeitschrift für Rechtswissenschaft. By Mittermaier and others. Heidelberg, 1830.
Zeitschrift für Deutsches Recht. By Beseler and others. Tübingen, 1840.
Jahrbücher der Deutschen Rechtswissenschaft. By Schletter. Erlangen, 1855.
Law Journal. London, 1823.
Law Magazine. London, 1829.
Legal Observer. London, 1831.
Jurist. London, 1837.
Calcutta Legal Observer. 1840.
Law Reporter. By Sanger. Boston, 1838.
American Law Register. By Fish and Wharton. Philadelphia, 1852.

MATHEMATICS.

Annales de Mathématiques. Founded by Gergonne, now edited by Terquem and Gerono. Paris, 1810.
Journal de Mathématiques. By Liouville. Paris, 1836.
Journal für Mathematik. Established by Crelle, now conducted by Borchardt. Berlin, 1826.
Zeitschrift für Mathematik und Physik. By Schlömilch and others. Leipsic, 1856.
Quarterly Journal of Mathematics. By Sylvester, Ferrers, and others. London, 1857.
Mathematical Journal. By Runkle. Cambridge, Mass., 1859.

MEDICAL SCIENCES.

Revue Médicale. Paris, 1820.
Journal de Médecine. Paris, 1829.
Annales d'Hygiène publique. Paris, 1829.
Archives générales de Médecine. Paris, 1823.
Bulletin général de Thérapeutique. Paris, 1830.
Journal des Connaissances médicales. Paris, 1832.
Revue de Thérapeutique. Paris, 1834.
Abeille médicale. Paris, 1844.
Journal de la Physiologie. By Brown-Séquard. Paris, 1858.
Jahrbücher der gesammten Medicin. By Richter and Winter. Leipsic, 1835.
Vierteljahrschrift für die praktische Heilkunde. By Halla and Kraft. Prague, 1844.
Archiv für Anatomie. Founded by J. Müller. Berlin, 1839.
Medicinische Zeitung. By E. Müller. Berlin, 1831.
Archiv für pathologische Anatomie. By Virchow. Berlin, 1851.
Zeitschrift für Wundärzte. By Hahn and others. Stuttgart, 1847.
Allgemeine medicinische Zeitung. By Posner. Berlin, 1830.
Edinburgh Medical Journal. 1805.
Medico-Chirurgical Review. London, 1820.
Lancet. London, 1823.
Dublin Journal of Medical Science. 1832.
Retrospect of Medicine. By Braithwaite. London, 1842.
Medical Critic and Psychological Journal. By Winslow. London, 1861.
American Journal of the Medical Sciences. By Hays. Philadelphia, 1828.
Medical and Surgical Journal. Boston, 1829.
New York Journal of Medicine. 1843.
Medical News. Philadelphia, 1843.
Medical and Surgical Journal. By Dowler. New Orleans, 1851.
Journal de la Société Gallicane de Médecine homéopathique. Paris, 1851.
Allgemeine homöopathische Zeitung. By Meyer. Leipsic, 1831.
Homöopathische Vierteljahrschrift. By C. Müller. Leipsic, 1850.
Zeitschrift für homöopathische Klinik. By Hirschel. Dresden, 1856.
North American Journal of Homœopathy. New York, 1852.
American Homœopathic Review. New York, 1859.
Archiv für Ophthalmologie. By Arlt and others. Berlin, 1855.
Irrenfreund. By Koster. Paderborn, 1859.
American Journal of Insanity. Utica, 1844.
Art Dentaire. By Preterre. Paris, 1857.
British Journal of Dental Science. London, 1857.
New York Dental Journal. By Norton. New York, 1858.
Journal de Pharmacie et de Chimie. Paris, 1809.
Vierteljahrschrift für praktische Pharmacie. By Wittstein. Munich, 1852.
Pharmaceutical Journal. London, 1841.
American Druggists' Circular. New York, 1857.
Journal de Médecine vétérinaire. Paris, 1845.
Magazin für die gesammte Thierheil-Kunde. Berlin, 1835.
Veterinarian. London, 1828.

METAPHYSICS.

Zeitschrift für Philosophie und speculative Theologie. By I. H. Fichte. Bonn, 1837.

MILITARY SCIENCE.

Journal des Sciences militaires. By Corréard. Paris, 1825.
Allgemeine Militär-Zeitung. Darmstadt, 1826.
Militair-Literatur-Zeitung. By Blesson. Berlin, 1830.
United Service Journal. London, 1829.

MINING.

Annales des Mines. (Continuation of the Journal des Mines.) Paris, 1795.
Berg- und hüttenmännische Zeitung. By Hartmann. Quedlinburg, 1842.
Oesterreichische Zeitschrift für Berg- und Hüttenmänner. By Hingenau. Vienna, 1858.
Mining Journal. London, 1842.
Mining Magazine. New York, 1853.

MUSIC.

France Musicale. By Escudier. Paris, 1837.
Zeitschrift für Musik. By Brendel. Leipsic, 1835.
Deutsche Musik-Zeitung. By Bagge. Vienna, 1860.
Dwight's Journal of Music. Boston, 1852.
Musical Gazette and Review. New York, 1860.

NATURAL SCIENCES.

Annales des Sciences naturelles. By Brongniart and Milne-Edwards. Paris, 1824.
Institut. Paris, 1833.
Cosmos. Founded by Montfort, continued by Moignot. Paris, 1852.
Archiv für Naturgeschichte. By Erichsen. Berlin, 1835.

PERI, the name of a class of imaginary beings in the Persian mythology, supposed to be descended from the fallen angels, and to be compelled to do penance for their sins before they can enter paradise. They are allied to the elves and fairies of the northern nations.

PERIPATETIC PHILOSOPHY. See ARISTOTLE.

PERIPNEUMONY. See PNEUMONIA.

PERITONEUM (Gr. περί, around, and τείνω, to stretch), the thin, transparent serous membrane which lines the abdominal cavity of man and vertebrates, reflected upon most of its contained organs and more or less completely enveloping them, and keeping them in place by its folds and prolongations. Like other serous membranes, it is a closed sac, covering but not containing the organs in its cavity; its internal surface, in contact with itself, is smooth and shining, moistened by a serous fluid which permits the natural movements of the organs upon each other. The folds which surround the small intestines, with their vessels, nerves, and glands, constitute the mesentery; this is attached to the vertebral column, retaining the canal in its proper place, and at the same time allowing the necessary motions of each portion; the folds which embrace the colon and rectum are called respectively the *mesocolon* and *mesorectum*. The double membranous fold, prolonged like an apron from the convexity of the stomach and colon, and floating free over and in front of the intestines, is the *omentum* or *epiploon*; it is supplied with numerous vessels, and is more or less charged with fat; it serves to keep the intestines in place, and to protect them and the vessels from external injury. In the male fœtus it sends a prolongation which accompanies the testis in its descent and becomes the *tunica vaginalis*, which in most cases is shut off from the peritoneal cavity and is the usual seat of hydrocele; in the female a small process enters the crural canal; the broad ligaments of the uterus are also peritoneal expansions. The kidneys and portions of other organs are outside of the peritoneum; it forms the ligaments of the liver and covers the lower surface of the diaphragm; its course upon the organs is very complicated. It is liable to common acute inflammation, exceedingly painful, and dangerous from its extent and connection with important organs; the puerperal state is subject to a speedily fatal form of peritonitis.

PERITONITIS, inflammation of the serous membrane which lines the cavity of the abdomen and invests the viscera which are contained in it. Acute idiopathic peritonitis is an affection so rare, that doubts have been raised as to its occurrence, the cases that have been described by authors being attributed to the rupture of an aneurism, or some minute perforation which has been overlooked in the course of the examination. But though peritonitis is one of the rarest forms of inflammation, there is not sufficient ground for this opinion. Dr. Simpson of Edinburgh has collected a number of instances in which peritonitis occurred during intra-uterine life; other observers have found it in new-born infants. Prolonged exposure to cold appears to be the only cause to which spontaneous peritonitis has been ascribed. The disease commonly commences with a chill more or less prolonged, and followed by heat of skin, frequency of pulse, and pain in the abdomen greatly increased by pressure. Sometimes the pain is constant, sometimes it is aggravated in paroxysms; at others it is increased by motion, and the patient commonly lies on the back with the knees drawn up, to relax the abdominal muscles and keep off the weight of the bedclothes. The respiration is hurried and is entirely thoracic, the abdomen being kept as still as possible; coughing, sneezing, &c., are extremely painful, and consequently suppressed; this is likewise the case with the effort to evacuate the bladder, and in the progress of the disease it is often necessary to have recourse to the catheter. In the commencement, in a few cases, particularly in muscular subjects, the abdomen is retracted; but very generally swelling of the bowels occurs. In the progress of the complaint effusion takes place into the cavity of the abdomen; but this is small in amount, and frequently cannot be detected during life. The bowels are generally very much constipated, though diarrhœa may be present. Hiccough and vomiting are apt to come on, the matters vomited being at first the contents of the stomach, and afterward a thin liquid in which a greenish substance is diffused. This last is often brought up in large quantities, and when vomiting once takes place it usually persists to the last. The disease when fatal is apt to be rapid in its progress, and death commonly occurs at the end of a few days, though it may be delayed much longer; its approach is heralded by extreme frequency and smallness of the pulse, and coldness of the extremities. Delirium is rarely present, the intellect being commonly clear to the last. On post-mortem examination more or less flocculent serum is found in the cavity of the pelvis or of the abdomen; the intestines are glued together by coagulable lymph, and the peritoneal surface is found to have lost its polish and become sticky. Where the patient recovers, the intestines are left matted or glued together, by which the peristaltic action may be materially interfered with, or fibrinous bands are formed which may cause strangulation of the gut.—Puerperal peritonitis, the most frequent form, occurs during child-bed, and commences with a strong and marked chill, which often lasts several hours. The pain at first is confined to the lower portion of the bowels, but as the peritonitis spreads it extends over the abdomen. Tympanitis is a marked symptom, and from the laxity of the walls of the abdomen, the swelling is often enormous; the pulse is very small and frequent, beating from 120 to 160 in a minute. The patient commonly lies on her back with the legs drawn up. Vomiting is apt to be early present, and the matters vomited, resembling a mixture of verdigris and water, are characteristic of the disease. The secretion of milk ceases, and the lochial discharge is generally suppressed. The disease is the scourge of lying-in hospitals and asylums, and sometimes occurs epidemically. Similar in its character to puerperal peritonitis is that form of the disease which sometimes, but rarely, comes on in menstruating women; here too, as in the former case, the disease appears to spread from the uterus to the peritoneum.—Next to puerperal peritonitis, that from perforation of the intestine is the commonest form of the disease. It may arise from perforating ulcer of the stomach, from the ulceration of Peyer's glands in typhoid fever, from that of phthisis or of dysentery, from the ulceration that sometimes supervenes in the appendix vermiformis, &c.; and occasionally it is caused by the rupture of a cyst, an abscess, or an aneurism. It is characterized by the sudden occurrence of acute pain in some part of the abdomen, which soon extends over its whole surface, is increased by pressure, and accompanied by a marked alteration of the pulse and the features. The disease is rapid in its course, the patient generally dying within 72 hours, though life in some cases has been prolonged beyond a week. Peritonitis is apt to arise in cases of ovarian cysts, of cancer and abscess of the liver, &c.; but the disease in these cases is commonly partial, and results only in the exudation of lymph and the gluing together of the adjacent surfaces of the membrane.—When general peritonitis occurs in a robust, healthy, young adult, the treatment may be commenced by a full general bleeding; in most cases the application of leeches to the abdomen, followed by the use of warm fomentations, will be all that is allowable. Main reliance in the treatment is often placed upon opium; this should be given at intervals of from half an hour to an hour, in such doses as will completely quiet the pain, and its use should be steadily persevered in until the termination of the disease. In this way a few patients have been cured whose cases seemed perfectly hopeless. Mercury, aconite, and *veratrum viride* have also been used successfully.—In some instances, and almost exclusively in tuberculous subjects, peritonitis puts on a chronic form. According to Louis, who has studied this subject with his customary accuracy, chronic peritonitis may be regarded as existing wherever: "1, the patient has suffered from general pain in the abdomen, not acute, but breathlessness and without diarrhœa; 2, an increase takes place in the volume and sonority of the belly, early accompanied by manifest fluctuation, without the existence of organic disease of the abdominal viscera, particularly of the liver, or of the heart or kidneys; 3, the more or less rapid subsidence of the effusion, leaving the belly slightly and generally swollen, permits the convolutions of the intestines to be seen distended in consequence of the difficulty with which their contents are passed onward; the whole attended by a weakness which can neither be accounted for by the condition of the lungs nor by the amount of the excretions." To the symptoms given by Louis we may add the dry crepitation on pressure noticed by Dr. Bright. The disease is generally fatal, though its course is a chronic one, and is very little influenced by treatment.

PERIWINKLE, in zoology, a pectinibranchiate gasteropod shell, of the genus *littorina* (*Férussac*). The shell is univalve, with a few spiral whorls, the horny operculum made up also of a few spiral turns; the tentacles are 2, the 2 eyes being at the base on the outside; the mouth is at the end of a proboscis, the gills comb-shaped, and the foot moderate, with a groove on the lower surface. The common periwinkle of the English and French coasts (*L. littoralis*, Linn.) is round, brown, longitudinally streaked with blackish; the shell is thick, and without pearly lining; it is oviparous, and lives in the lowest zone of sea weed between low and high water marks; immense quantities are brought to the London market, and form a considerable article of food for the poorer classes. The rough periwinkle (*L. rudis*, Mat.), from the ocean washing the shores of Europe, frequents a higher zone of sea weed; this is ovo-viviparous, and the young acquire a calcareous shell before they are excluded, for which reason the species is not eaten. There are many other species, all marine, inhabiting almost all parts of the globe, living on the rocks between the tide marks; three species are very common on the coast of New England, of small size, and probably never eaten.

PERIWINKLE (Ang. Sax. *pinewincle*; Lat. *pervinca*; Fr. *pervenche*), in botany, the common name of plants of the genus *vinca* (Linn.), of the natural order *apocynaceæ*. The plants of this order are perigynous exogens with no stipules, opposite and sometimes whorled leaves, and a somewhat corymbose inflorescence, with a free, 5-parted, persistent calyx; monopetalous, 5-lobed, deciduous corolla, with a contorted æstivation; 5 stamens arising from the corolla alternating with its segments; ovaries 1 or 2 celled and many-seeded; styles 1 or 2; stigma 1; fruit a follicle, capsule, drupe, or berry, double or single; seeds with a fleshy or cartilaginous albumen. The genera are principally tropical, a few representatives being known in northern latitudes. Among the latter is the *vinca*, the distinctive characters of which are: a 5-cleft calyx with linear acute segments, salver-shaped corolla with its tube longer than the calyx, throat bearded, segments of the limb flat, oblique, truncate at apex; stamens 5, inserted in the throat; stigma bearded, seated on a flat orbicular disk, which is grooved round the circumference; glands 2, alternating with the ovaries; fruit consisting of 2 follicles and few-seeded, dehiscing lengthwise; seeds cylindrical, naked, with fleshy albumen. The greater periwinkle (*V. major*, Linn.) has rather erect stems; ovate, acute, ciliated leaves; fine purplish blue flowers, the calyx with linear, subulate, ciliated divisions, the corolla with 5 broad obovate parts; the flowers appear upon short erect stems, while the long trailing ones are barren. There is a variety which is much esteemed for its variegated, yellowish-white striped and margined leaves. As a trailing evergreen this species is admirably adapted for covering the ground under hedges, ornamental trees, and shrubbery that has tall and bare stems. It flowers all summer. In the northern states it is commonly cultivated in large pots, which, placed upon pedestals, allow the long pendulous stems to hang gracefully down. It is easily propagated by the spontaneous rooting of its branches, chiefly at the tips or points, or by the division of its roots. If the seeds are needed, the plant should be kept in a shallow pot with very little earth and the lateral shoots cut away. The lesser periwinkle (*V. minor*, Linn.) has procumbent stems; elliptic-lanceolate, glabrous leaves; segments of the calyx linear-lanceolate, bluntish; segments of the corolla broadish at top; flowering stems usually erect; flowers blue with a white throat, varying to purple and white, and of much smaller size than those of the preceding. Both are found growing spontaneously in various parts of Europe. There are several beautiful varieties of the common or lesser periwinkle, such as a double blue-flowered, a double red-flowered, a single white-flowered of great delicacy of blossom, a yellow variegated-leaved, and a white variegated-leaved. The extreme hardiness of this species renders it acceptable for planting in shady places, where it covers the ground and produces a pleasing effect, increasing rapidly by its rooting stems. The herbaceous periwinkle (*V. herbacea*, Willd.) is an elegant plant of Hungary, with herbaceous prostrate stems, oblong-lanceolate, smooth leaves, stalked flowers, and a ciliate calyx; the corolla is of a pale blue color. The Madagascar periwinkle (*V. rosea*, Linn.) has an erect branching stem, ovate-oblong leaves, and twin sessile flowers of much elegance. There are two varieties, a pure white-flowered, and another with the same color set off by an eye or colored spot in the throat. These are fine pot plants, requiring much heat in winter, but doing well in a sunny open border during the summer.

PERJURY, the crime of false swearing. He commits perjury, who, under oath lawfully administered in a judicial proceeding or course of justice, wilfully gives false testimony material to the issue or point in question. The offence is thus defined at common law. In many of the United States it is particularly defined by statutes; but these do not vary materially from the common law definition. It is to be observed, first, that a judicial procedure or course of justice is essential to the commission of it. It may be stated generally that wherever, under the common law of the land, an oath is required in the regular administration of justice, there the crime is possible. The offence cannot be founded on the violation of a mere oath of office. For example, an officer, public or private, who neglects to execute his office in pursuance of his oath, or acts contrary to the tenor of it, is not indictable for perjury. Nor can perjury consist of the violation of an oath taken in any purely extra-judicial proceeding; as a false affidavit to an account to be rendered by an administrator, or false swearing before a justice of the peace, before whom no cause in any stage is pending. So, though false testimony, given before a commissioner appointed by a court under the common rule, is perjury, yet it is not so when given in depositions taken by consent before unauthorized persons. It matters not whether the untrue evidence were given in the principal investigation of the matter in issue, or whether it were in some preliminary or incidental proceeding. If the matter sworn to in these proceedings is material, though only remotely so, the crime of perjury is possible. Not only, therefore, may it be committed by a witness who is giving oral testimony in a trial in open court, but it may be as well in the preliminary information or complaint before a magistrate, or in statements made before the grand jury, or in a deposition made before a commissioner duly authorized to take it. So the examination of a poor debtor before a magistrate is a course of justice, and false swearing there is perjury. The hearing of a cause must furthermore be really, not apparently only, a judicial proceeding. For, if a judge who seemed to have authority, yet had none in fact, administered the oath, or if a suit, though properly brought, had yet in fact abated by the death of a party, and thus passed out of the court's jurisdiction, false swearing in either case is not indictable. But perjury is not excused if the pleadings were merely informal and amendable, or if the proceedings were voidable but not void. It is further essential that an oath was lawfully administered. The indictment therefore usually recites that the party was in due manner sworn and took his corporal oath to speak the truth. It is enough, however, to avow that the party was duly sworn, without alleging the mode in which the oath was administered. Yet, if the allegation be of a specific mode, a variance in the proof will be fatal; and perhaps the indictment would fail if it charged that the party was sworn, when in fact he only made solemn affirmation of the truth. The oath, as we have already impli can be well administered only by compet authority, and before a court or magistrate h ing legal right to proceed in the cause. suffices in the indictment to allege this competent power and authority without setting the facts which constitute jurisdiction.— proof of the falsity of the testimony, which also an essential element of the offence, it not requisite to recite the exact words uttere with the same nicety as in the case of forg or libel. It is sufficient to allege substanti what the defendant said as to the matter question, and that he knew it to be false. we have already seen, the untruth may lie only in evidence given in a court of law, it may lie in a false affidavit to a bill in eq which prays for an injunction, or to a petit for the writ of *habeas corpus*. The per may also consist in a false oath made under insolvent debtor's act, in false evidence gi before a grand jury, or in the false and m cious exhibition of articles of the peace. also well settled that the false testimony m be given wilfully. It has sometimes been h that the allegation of wilful and corrupt hood is well supported by evidence that th cused swore rashly to that which he did n know, and, though he believed it, yet had probable cause for believing. But the be opinion seems to be, that perjury is not c mitted if the party gave his testimony in cordance with his belief, no matter how care lessly or rashly that belief may have be formed. In other words, a distinct corr intent is essential to the crime.—Finally, th false testimony must be material to the p in controversy. The degree of materi is of no importance, nor is it necessary the false declaration immediately and dire touch the issue; it suffices if it rem or collaterally affect it. Perjury then may committed, if the testimony tend to increase or diminish the damages or punishment, or if concern the credibility of the witness hims or of any other witness in the case. A fa answer to a question put by way of cr examination may therefore lay the foundati of an indictment; and it has been held to be perjury where a party, after being particularly cautioned as to his reply, answered falsely to an interrogatory, put merely with the design of impairing his credit as to that part of the evidence which was immediately material.

PERKINS, Elisha, an American physician, the inventor of the metallic tractors, born in Norwich, Conn., in Jan. 1740, died in New York in Sept. 1799. He was educated by his father for the profession of medicine, and began the practice of it in Plainfield, where he was very successful. About 1796 he invented the metallic tractors, consisting of two instruments, one resembling brass and the other steel, but professedly of a peculiar composition of metals, 8 inches in length and pointed at the ends. They were used chiefly in local inflammations, such as pains in the head, face, teeth, and side, in rheumatism and diseases of a similar character, the points being applied to the affected part, and then drawn over it in a downward direction for about 20 minutes. For a time this method of cure enjoyed great reputation, not only in America but in Europe. In the United States the faculty of 3 institutions recommended it. In Copenhagen 12 physicians and surgeons, most of them instructors in the royal Frederick's hospital, began a course of experiments, an account of which was published in an 8vo. volume, and gave their opinion in favor of the new system, which they called Perkinism. In London, where the tractors were introduced by Dr. Perkins's son, a Perkinian institution, under the presidency of Lord Rivers, was established, chiefly for the benefit of the poor. The cases of cures published numbered 5,000, and were certified to by 5 professors, 40 physicians and surgeons, and 30 clergymen. The list of persons claimed to have been cured by this remedy amounted to an almost fabulous number; but the tractors fell into neglect almost as speedily as they had become celebrated. Dr. Perkins invented also an antiseptic medicine, and, anxious to test its efficacy against the yellow fever, he repaired to New York in 1799 during the prevalence of that disease; but after 4 weeks of unremitting toil, he himself died of the fever.

PERKINS, George Roberts, LL.D., an American mathematician and astronomer, born in Otsego co., N. Y., May 3, 1812. He was almost wholly self-educated, and at the age of 15 was employed as assistant engineer in the slackwater survey of the Susquehanna river; but his labors were interrupted by a severe lameness, which afflicted him for several years. At the age of 19 he was employed as a teacher of mathematics in the "Liberal Institute" at Clinton, N. Y., where he remained till 1838, when he became principal of the Utica academy. In 1844, at the opening of the state normal school, he was chosen professor of mathematics, and 4 years later was elected principal. In 1852 he was compelled by ill health to resign, and soon after superintended the erection of the Dudley observatory. In 1856 he was elected professor of mathematics in the university of the state of Iowa, but never entered upon his duties there. In 1856 he was appointed deputy state engineer and surveyor of the state of New York, an office which he still holds. He received from Hamilton college the honorary degrees of A.M. in 1839, and LL.D. in 1852. He is the author of a series of mathematical text books for colleges, academies, and public schools, comprising "Primary," "Elementary," "Practical," and "Higher" arithmetics, published between 1840 and 1851; "Treatise on Algebra" (1841); "Elements of Algebra" (1844); "Elements of Geometry" (1847); "Trigonometry and Surveying" (1851); "Plane and Solid Geometry" (1854). It is understood that he is preparing a text book on astronomy.

PERKINS, Jacob, an American inventor, born in Newburyport, Mass., in 1766, died in London, July 30, 1849. He was apprenticed to a goldsmith, and early distinguished himself by the invention of a new method of plating shoe buckles, in the manufacture of which he engaged with considerable success. When he was about 21 years of age he was employed by the commonwealth of Massachusetts to make dies for copper coinage. Soon afterward he invented a machine for cutting and heading nails at one operation, but he lost the fruits of this valuable improvement through the mismanagement of his partners, and was involved in great pecuniary distress. In bank note engraving he next made most important improvements, substituting steel for copper plates, and, having obtained an elaborate and costly impression, transferring this by pressure to other steel plates, which could be afterward hardened and used for printing from. (See Engraving, vol. vii. pp. 211, 213, 214.) About 1814 he went to Philadelphia and became associated with the firm of Murray, Draper, and Fairman, bank note engravers, and in 1816 went to England, accompanied by Mr. Fairman and a number of workmen, with the expectation of obtaining a contract for supplying the bank of England with plates. In this he was disappointed, but he obtained a similar privilege from the bank of Ireland, and in partnership with Mr. Heath carried on his business in London for a number of years. He also became interested in the subject of steam artillery, in which Watt and others after him had already made experiments with more or less success. Having constructed a gun in which steam, generated at an enormous pressure, was used as the propelling power instead of gunpowder, he instituted a series of experiments in the presence of the duke of Wellington and a number of artillery officers, which demonstrated the feasibility of his plan, though it has been generally condemned as inapplicable to modern warfare. An iron target, at a distance of 35 yards, was shattered to atoms. Balls passed through 11 planks of the hardest deal, each 1 inch thick, placed some distance apart, and with a pressure of only 65 atmospheres penetrated an iron plate ¼ inch thick. To demonstrate the rapidity with which the balls might be thrown, he screwed to a gun barrel a tube filled with balls, which falling into the barrel by their own weight were discharged at the rate of nearly 1,000 per minute. A movable joint being attached to the gun barrel and a lateral direction given to it, a lineal series of holes was perforated in a plank nearly 12 feet long. The expense of working such a gun was calculated at about $\frac{1}{50}$ part of the cost of the powder required to discharge an equal number of balls by the usual method. The greatest objections to the application of steam to artillery are, the impossibility of giving it the force of gunpowder, and the complex machinery required, which in actual battle could seldom be properly managed. Mr. Perkins also invented an instrument called the bathometer, to measure the depth of water, and the pleometer, to mark with precision the speed at which a vessel moves through the water; and he was the first to demonstrate that water is compressible.

PERKINS, Thomas Handasyd, an American merchant, born in Boston, Mass., Dec. 15, 1764, died in Brookline, Jan. 11, 1854. His father was a merchant. His early education was obtained at Middleborough, Barnstable, and Boston, and he was fitted for college at Hingham; but his love of a mercantile life was so strong that he was finally permitted to enter the counting house of the Messrs. Shattuck in Boston, with whom he remained until attaining his majority. He then spent some time with his elder brother James, and became associated with him in a mercantile house in St. Domingo. The climate proving prejudicial to his health, he returned to Boston, and attended to the interests of the house there, while a younger brother took his place at St. Domingo. In 1789 he went as supercargo of the ship Astræa, commanded by his relative Capt. Magee, to Batavia and Canton, and there laid the foundation of his subsequent extraordinary mercantile success, by forming a thorough acquaintance with the oriental trade. After his return he made, in connection with Capt. Magee, several successful ventures in the Pacific, on the north-west coast, and in China. In 1792 the insurrection in St. Domingo destroyed most of the property of his brother's house there, and, ruining their debtors, also brought them to the verge of bankruptcy. On their return to Boston, Mr. Perkins formed a partnership with his brother James, which for the next 30 years was remarkable for the extent, foresight, and success of its enterprises. In 1795 he visited France and Holland on business, and was detained in the former country some months, while the later scenes of the revolution were in progress. Here he had the opportunity of rendering important services to the wife and son of Lafayette, as well as to some of his own countrymen. In 1805 he was elected to the Massachusetts senate, and for 18 or 20 years subsequently he was most of the time a member of one or the other branch of the legislature. He was repeatedly offered a seat in congress or the cabinet, but he had no taste for political honors. In the promotion of all objects which could improve the physical, social, and moral condition of the community, Mr. Perkins took a lively interest. In 1815 the effort was made to endow the Massachusetts general hospital, and $100,000 was required within a limited time. Mr. Perkins's name was placed at the head of the first list of trustees, and he and his brother contributed $5,000 each toward the fund. In 1826 additions were to be made to the Boston Athenæum, and Mr. Perkins and his nephew each contributed $8,000 toward it, thus making up half the required sum. In 18
his mansion house and grounds in P
worth over $50,000, for a blind a

PERM, a government of Russia, lyi
in Europe and partly in Asia, bound
Vologda and Tobolsk, E. by Tobolsk
Orenburg, and W. by Viatka. It exten
lat. 56° 18′ to 61° 55′ N., and from
30′ to 64° E.; extreme length 500 m.
450 m.; area, 130,000 sq. m.; pop.
2,012,308. The Ural mountains, wh
the boundary line between Europe
traverse it in a N. and S. direction,
the government into two unequal par
in Europe being the larger. Pavdinsk
men, the loftiest summit in the govern
more than 6,000 feet above the sea; a
principal pass across the Ural leads b
gur, between Perm and Tobolsk. Fro
principal chain the surface descends in a
of terraces, and a great part of it is mou
ous. The European portion belongs p
pally to the basin of the Caspian, and th
atic to that of the Arctic ocean. The K
an affluent of the Volga, enters the govern
from the N. W., and leaves it at the S. W.
ceiving many tributaries, the most imp
of which are the Vitchera, Kosa, Kosva,
and Tchusovaya. The E. part has several
and is drained by numerous tributaries of
Obi, the largest of which are the Sosva, L
Tura, Neiva, Irbit, Pishma, Iset, and M
The climate of the elevated regions and of
N. is cold and bleak. Gold, silver, platin
iron, copper, lead, diamonds and other prec
stones, loadstone, salt, and marble are
found. The S. W. part is generally fertile,
elsewhere the soil is better suited for past
than agriculture, and much of it is uncultivat
Rye, barley, oats, potatoes, flax, and differe
vegetables are grown. Oak, elm, cedar, pi
and larch are the chief trees. The mines a
extensively worked. In 1855 the 8 princi
mines belonging to the crown yielded 3,
lbs. of gold, 11,498 cwt. of copper, 8 lbs. 9
of platinum, and 59,311 cwt. of iron. Cl
leather, soap, glass, and candles are mad
About ¾ of the inhabitants are Russians, a
the remainder are composed of various Tarta
tribes, the descendants of the aborigines of the
country. By far the greater part belong to
the Greek church, but there are some of other
Christian sects, and about 4 per cent. are M
hammedans.—The capital, Perm, is situated on
the left bank of the Kama, in lat. 58° 1′ N., long.
56° 26′ E.; pop. in 1851, 13,262. The houses

chiefly constructed of wood. There are 9 [illegible], several public buildings, a convent, [illegible] hospitals, a gymnasium, a theological seminary, [illegible] extensive iron founderies, and copper refineries.

PERMUTATION. See COMBINATION.

PERNAMBUCO, an E. province of Brazil, bounded N. by the provinces of Ceará and Parahiba, E. by the Atlantic, S. by Alagoas and Bahia, and W. by Piauhi; extreme length 700 m., breadth 220 m.; area, according to the latest authority, about 52,000 sq. m.; pop. in 1856, 950,000. The coast is low and fronted by numerous coral reefs which render navigation dangerous. The country is flat with a sandy soil for about 15 m. from the sea, but it afterward becomes hilly, and gradually rises into mountains and extensive table-lands. The most important river is the San Francisco, which forms a part of the boundary on the S., and receives the drainage of the greater part of the province by several tributaries. In the N. E. the Capibaribe, Ipojuca, and some smaller streams flow directly to the ocean. Marble is abundant, and gold is found in small quantities. The soil is in many places rich and fertile, and produces sugar cane, cotton, maize, mandioc, fruits and vegetables, and many kinds of medicinal herbs. A great part of the mountainous country is covered with forests, which yield excellent timber, dye woods, balsams, and gums. The manufactures are trifling, but there are numerous sugar works and distilleries where many slaves are employed. Great improvements have been lately made in the roads of the province; and a railway is in course of construction which is to open the interior for about 300 m.—The capital, PERNAMBUCO, or RECIFE, is situated at the mouth of the Capibaribe, in lat. 8° 4′ S., long. 34° 52′ W.; pop. about 80,000. It consists of 3 distinct parts, Recife, Boavista, and St. Antonio, and of the town of Olinda, which is about 3 m. distant. Recife stands on a peninsula, Boavista on the mainland, and St. Antonio on an island or sand bank formed by the river. Recife is the principal seat of commerce. The streets are narrow, and the houses generally built of brick from 2 to 5 stories high. St. Antonio is connected with Recife by a long bridge. Boavista is the most modern quarter. The 3 divisions contain many churches, monasteries, charitable institutions, and other public buildings. The town is extremely dirty, and drinking water has to be brought in casks from Biberibe near Olinda. The harbor is formed by a reef which acts as a kind of breakwater, but in stormy weather the swell passes over and through different openings in it. The depth varies from 16 to 30 feet, but the best sheltered part has only about 10 feet. It has a good lighthouse and is defended by several forts. The trade of Pernambuco is very important, and has been steadily increasing for some years past. In 1859, 70 American vessels entered the port. The exports consist chiefly of sugar, cotton, rum, hides, and dye woods; and the imports of cotton and woollen cloth, hardware, cutlery, silks, wine, flour, salt fish, and pine boards. The chief imports from the United States in 1858 were 20,856 barrels of flour and 240,900 drums of codfish.—Recife was founded by the Portuguese early in the 16th century, was sacked by the English under Capt. Lancaster in 1595, and was in the possession of the Dutch from 1630 to 1654.

PÉRON, FRANÇOIS, a French traveller and naturalist, born in Cérilly, department of Allier, Aug. 22, 1775, died there, Dec. 14, 1810. He enlisted as a volunteer in 1792, was wounded at the siege of Landau, and made a prisoner at the battle of Kaiserslautern, and taken to the citadel of Magdeburg. He devoted his captivity to reading travels and histories, and was released in 1794. In 1800, through the influence of Jussieu and Lacépède, he was attached, in the capacity of zoologist, to the expedition sent by the French government under Capt. Baudin to explore Australia. He made curious experiments showing that the coldness of the sea water increases with the depth, and succeeded in bringing home an invaluable zoological collection, comprising more than 2,500 species previously unknown. The results of his observations have been embodied in his interesting narrative of the *Voyage de découvertes aux terres australes pendant les années* 1800–1804 (3 vols. 4to., with an atlas, Paris, 1807–'16). The 3d volume was prepared after his death by M. de Freycinet. He had previously published *Observations sur l'anthropologie* (Paris, 1799).

PÉROUSE, LA. See LA PÉROUSE.

PERPETUAL MOTION, a term the primary meaning of which is obvious enough, and which is in such sense applicable to actual phenomena, as the planetary movements; but which has been wrested from this, its proper use, to name any imaginary mechanism, such that, within itself, the power required to give it motion shall be continually restored or renewed, without aid from an exterior source or cause. Of course, such a machine, once in motion, must move for ever, or until destroyed by the wear of its parts. The idea necessitates a circle or circuit of parts, returning in some way upon itself; it implies the uninterrupted transfer of a certain quantity of motion from piece to piece through the circuit, or such accumulation at one point as shall overcome the resistance at another, so that an undiminished force returns always upon the first piece (prime mover), the machine being thus required to impel itself, and if possible perform over and above this some useful work. This problem, wrought upon through 2,000 years, and never more faithfully than within a century past, yet without one instance of positively attested success, has, aside from its demonstrated impossibility, deservedly attained to a "bad eminence" in the history of mechanics. Interminable have been the plans, devices, wheels, combinations, and engines to which these attempts, always in the nature of things absurd, have given birth. Two among the most distinguished of these attempts are that of the marquis of Worcester, 1659, and that of Jean Orffyre, or Orffyrens, a Frenchman, 1719; both these were wheels, moving by weights, their diameters 14 and 12 feet; but proof of their successful working remains insufficient.—First, what movements cannot be claimed as furnishing or solving the so called perpetual motion? The earth and other planets incessantly rotate and advance in their orbits; but the resistances they meet being 0, or infinitesimally small, no perceptible retardation results. By the first law of motion, they can never stop, save owing to some extraneous opposing force; and so, the air and gravity being removed, every ball propelled from a school boy's club must move forward with its first speed, in a right line and for ever. In truth, observation as yet reveals to us no body or particle of matter that is not in incessant motion through space. Thus, the real difficulty is not to find instances of perpetual motion, but to find any power adequate to arrest such motions. What the imaginative mechanist seeks is in no case a machine expected to go for ever; it is one that in time must wear out by the rub and grating of its parts; yet inconsistently, because ignorantly, he hopes to devise a machine that shall feed itself with needful power, and then yield a surplus with which to grind, saw, plane, &c. The continual movement of the tides; the use of a large tide wheel to fill a reservoir and feed constantly a smaller wheel; the turning of light wheel-work continually and rapidly by means of contrivances for reversing direction and multiplying velocity of movement of a piston rod resting on a body of oil in a tube, or of a long metallic bar fixed at one end, and due to small expansions and contractions of the oil or the bar; the oscillations of a pendulum aided by a spring; the incessant pulsation of the heart through 80 or more years—none of these afford the perpetual motion sought, because they are due to moving force from without, as to gravity, momentum, heat, elasticity, or finally to food. While oceans continue to evaporate, rains to fall, and rivers to return to the sea, by renewing our water wheels we secure perpetual power and work. But the over-ingenious busy themselves with projecting a water wheel that shall pump back to the top of the fall all the water required to run it, and meanwhile do some useful work beside. Now, any machinery is only a connected series of inert and inactive pieces, interposed between the point on which a motor acts and the material on which its work is to be done (see MECHANICS); and this being true, the supposition that the whole work of a machine shall far exceed, or in the least exceed, the whole power it can receive, is simply impossible and absurd. If it were possible, the only admissible cases must be those in which momentum due to inertia or to gravity, or attractions and repulsions, as of magnetic poles, can be made within the mechanism to do the work of propelling it. Viewed in any light, there are but 5 cases supposable: 1. An exterior moving power; but this is of course excluded. 2. Total annihilation of friction, resistance of air, rigidity, or softness when injurious, adhesion of parts to each other and of air to them all; but these conditions existing in the very nature and circumstances of bodies, to escape them is impossible. Their results are wear, and conversion of some of the force into heat; in either case, a definite and large subtraction from the total power. 3. Can the force generated or transmitted through any piece or connection be greater than that impressed upon or imparted to it by the pieces preceding it in the circuit? This might be supposed, if any ordinary machine had ever been found to yield a total work greater than the total power put upon it. In fact, the work equals the power; and part even of the former is waste work, expended on resistances. Positively, then, no part or connection of a machine can do what no entire ordinary machine can do—augment the total power. The urging body or piece always loses what the urged gains. M. De la Hire demonstrates that the problem of a perpetual motion in this aspect amounts to this: to find a body both heavier and lighter at the same moment; or to find a body heavier than itself; or to find a force greater than itself. 4. Is it possible, by any artful disposition and combination of contrivances, multiplied to any desired extent, to secure the end sought by successive accumulations of momentum within the parts? This appears more plausible, but only because the case is more complicated, and the law is here not so easily traced. In this direction the larger number of speculators have been led astray. The law applying here is that of virtual velocities: what is gained in the magnitude of effect of a power, is always lost in time; and *vice versa*. The very fact of a necessary circuit of parts forbids the gain that otherwise might occur by resolving the acting forces, or in any way restoring or adding momentum in some of the parts; in other pieces, if not at once, the equal reaction must have its effect. 5. Can a surplus of moving power be obtained by some succession of mechanical or electro-magnetic with magneto-electric apparatus? The recent discovery that the various other forms of force have each its exact equivalent in mechanical units (see HEAT), and that the conversion of forces either way is by equivalents, sets this question at rest, and shows that the law of equality of action and reaction is to be extended from simple mechanics to all moving agencies in nature. Thus it becomes a sure axiom of science, that there can be no self-impelled mechanism of human production. A knowledge of this truth would even now save the wasted time, talents, means, and peace of mind, if not even the sanity of thousands. In New York, in 1860, a mechanist having devised a modification of the fly-wheel, by which a single person could accumulate power enough, on coupling instantly, to move a heavy load, proposed to propel therewith by the power of one man a railway car. Mistaking a momentary for a permanent result, he believed that he had achieved the perpetual motion; and a gentleman more learned in civil than in mechanical law, before being warned of its necessary failure, expended on this contrivance nearly $3,000. The type of a vast number of these attempts, however, is a wheel, cylinder, or endless belt vertical over pulleys, so contrived that weights shall fall or roll out from the axis of motion, and press more, on the descending side, and then fall or roll in toward the axis, pressing less, on the ascending side; the aim being thus to get an excess of downward pressure. But calculation from a true drawing will always show a sufficiently greater proportion of the weights at any instant to be on the ascending side; and with inertia, concussion, and friction, the balance is always on the side of the resistances. One would let 15 feet of an endless chain glide down a vertical shaft turning on fine pivots on one side, while but 10 feet of straight chain rose on the other; while another would cause heavy balls to drop into pockets in the periphery of a wheel on the descending side, the balls to be discharged below, and then, by the excess of power gained, to be fed along and elevated in an Archimedes screw. In these, as in like devices, the actual and necessary result is a perpetual rest. At a leading patent agency in New York, it is stated that probably 15 persons apply yearly for patents for professed perpetual motions; considering the number of agencies, and the certainty that many projects of the kind are kept waiting for the "working model," without which they fail to be patentable, it is safe to conclude that the number of these contrivances at any time being planned or constructed must be, in the United States alone, many hundreds.—For an account of some of the remarkable attempts made in this direction during the present and two preceding centuries, see "Perpetuum Mobile, or Search for Self-Motive Power," by H. Dircks (London, 1861).

PERPIGNAN, a city in the S. of France, capital of the department of Pyrénées-Orientales, situated upon the right bank of the Tet, at its confluence with the Basse, 34 m. S. from Narbonne; pop. in 1856, 19,844. It commands the S. E. entrance to France from Spain by the Pyrénées, and is strongly fortified with a wall and fosse, and commanded by a citadel with a double line of defences, and a tall square tower or donjon. In character the city is Spanish. Its streets are narrow and dirty, and mostly shaded by awnings. The houses are semi-Moresque in style, furnished with wooden balconies and inner courts. Over the Basse there is a bridge of a single arch, and one of 7 arches over the Tet. The public buildings date from the Spanish period, and are built of brick or rolled pebbles. In the remains of the ancient university is the public library, which contains 20,000 volumes. The city has a theological seminary, a high school, a botanical garden, a government sheepfold for merinoes, two hospitals, manufactories of woollen cloth, hats, leather, soap, and soda, and a considerable commerce in red wines, liqueurs, brandy, oil, silk, wool, iron, and cork.—Perpignan is upon or near the site of the ancient Ruscino, a city of the Sordones. It was in ruins about A. D. 800, and near it sprang up an insignificant hamlet called then Corsch, which became the present city of Perpignan. It belonged, with the province, to the kingdom of Aragon, but was taken by the French in 1475, after having been reduced by famine. Restored to Spain in 1642, it was included in the cession to France of Roussillon in 1659. The Spaniards were defeated by the French under the walls of the city in 1794.

PERQUIMANS, a N. E. co. of N. C., bordered S. by Albemarle sound, and drained by Perquimans river; area about 200 sq. m.; pop. in 1860, 7,248, of whom 3,569 were slaves. It has a nearly level surface, and the soil is generally fertile. The productions in 1850 were 45,943 bushels of wheat, 418,255 of Indian corn, and 1,565 tons of hay. There were 3 saw mills, 2 grist mills, 1 tannery, 12 churches, and 375 pupils attending public schools. Capital, Hertford.

PERRENOT, ANTOINE. See GRANVELLE.

PERRON, ANQUETIL DU. See ANQUETIL-DUPERRON.

PERRY, the name of counties in 10 of the United States. I. A S. co. of Penn., bounded E. by the Susquehanna, and intersected toward the N. by the Juniata river and S. by Sherman's creek; area, 540 sq. m.; pop. in 1860, 22,940. Its surface is mountainous, the Tuscarora range forming its N. W. boundary and the Blue mountains the S. E., but much of the land is very fertile. The productions in 1850 were 190,607 bushels of wheat, 155,271 of Indian corn, 144,142 of oats, 16,690 tons of hay, 24,469 lbs. of wool, and 302,189 of butter. There were 48 grist mills, 45 saw mills, 5 woollen factories, 25 tanneries, 4 founderies, 2 newspaper offices, 40 churches, and 6,372 pupils attending public schools. It is intersected by the Pennsylvania railroad. Capital, Bloomfield. II. A central co. of Ala., intersected by the Cahawba river; area, 950 sq. m.; pop. in 1860, 27,727, of whom 18,208 were slaves. It has an undulating surface and fertile soil. The productions in 1850 were 934,116 bushels of Indian corn, 184,616 of sweet potatoes, and 24,524 bales of cotton. There were 6 grist mills, 5 saw mills, 8 tanneries, 20 churches, and 714 pupils attending public schools. Capital, Marion. III. A S. E. co. of Miss., intersected by Leaf river and Black creek, tributaries of the Pascagoula, and drained by their branches; area, 1,044 sq. m.; pop. in 1860, 2,606, of whom 788 were slaves. It has a broken surface and a not very fertile soil, covered with forests of pine. The productions in 1850 were 56,860 bushels of Indian corn, 44,-

980 of sweet potatoes, 88,000 lbs. of rice, and 388 bales of cotton. There were 6 churches. Capital, Augusta. IV. A central co. of Ark., bounded N. E. by the Arkansas river, and intersected by the Fourche la Fève, one of its branches; area, about 600 sq. m.; pop. in 1860, 2,465, of whom 303 were slaves. It has a diversified surface, and the soil is generally fertile, particularly near the streams. The productions in 1854 were 38,820 bushels of Indian corn, 256 of wheat, and 1,765 of oats. There were 2 saw mills and a grist mill. Capital, Perryville. V. A W. co. of Tenn., bounded W. by the Tennessee river, and intersected by Buffalo river, a branch of Duck river; area, about 400 sq. m.; pop. in 1860, 6,042, of whom 548 were slaves. Its surface is diversified, and the soil is generally fertile. The productions in 1850 were 395,535 bushels of Indian corn, 23,484 of oats, 16,051 of sweet potatoes, 940 lbs. of tobacco, and 41,686 of butter. There were 10 grist mills, a saw mill, a furnace, 2 tanneries, 21 churches, and 685 pupils attending public schools. Capital, Humphreysville. VI. A S. E. co. of Ky., drained by the North and Middle forks of the Kentucky river; area, about 700 sq. m.; pop. in 1860, 3,950, of whom 73 were slaves. It has a mountainous and rugged surface, the valleys being arable and fertile, and the higher lands adapted to wool growing. The productions in 1850 were 124,296 bushels of corn, 4,758 of oats, 2,669 lbs. of tobacco, and 11,288 of wool. There were 10 grist mills, 2 saw mills, and 7 churches. Capital, Hazard. VII. A S. E. co. of Ohio, drained by a number of small streams; area, 400 sq. m.; pop. in 1860, 19,679. It has an undulating surface and fertile soil. The productions in 1850 were 428,903 bushels of Indian corn, 160,048 of wheat, 101,591 of oats, 9,887 tons of hay, 104,526 lbs. of wool, and 261,806 of butter. There were 5 grist mills, 7 saw mills, 2 woollen factories, 2 newspaper offices, 61 churches, and 5,808 pupils attending public schools. It is intersected by the Cincinnati, Wilmington, and Zanesville railroad. Capital, Somerset. VIII. A S. co. of Ind., bounded S. and E. by the Ohio river, which separates it from Kentucky, and drained by Anderson's and other creeks; area, about 400 sq. m.; pop. in 1860, 11,857. It has a very hilly surface and a soil fertile along the streams. The productions in 1850 were 232,835 bushels of Indian corn, 33,475 of oats, 3,848 of wheat, 999 tons of hay, and 10,581 lbs. of wool. There were 5 grist mills, 9 saw mills, 3 tanneries, 1 newspaper office, 8 churches, and 476 pupils attending public schools. Capital, Rome. IX. A S. co. of Ill., intersected by Beaucoup creek; area, about 430 sq. m.; pop. in 1860, 9,552. It has a diversified surface, and much of the soil is fertile. The productions in 1850 were 363,300 bushels of Indian corn, 66,363 of oats, 15,988 lbs. of wool, and 119,079 of butter. There were 3 grist mills, a saw mill, a tannery, 5 churches, and 340 pupils attending public schools. It is intersected by the Illinois central railroad. Capital, Pinckneyville. X. A S. E. co. of Mo., separated from Illinois by the Mississippi river, and drained by several small streams; area, 430 sq. m.; pop. in 1860, 9,128, of whom 739 were slaves. It has a diversified surface and fertile soil. The productions in 1850 were 349,280 bushels of Indian corn, 65,895 of wheat, 42,916 of oats, 11,731 lbs. of wool, and 73,845 of butter. There were 7 grist mills, 4 saw mills, 3 tanneries, 14 churches, and 360 pupils attending public schools. Capital, Perryville.

PERRY, Matthew Calbraith, an officer of the U. S. navy, born in South Kingston, R. I., in 1795, died in New York, March 4, 1858. He was a son of Capt. Christopher R. Perry, U. S. N., and a brother of Capt. Oliver H. Perry. He entered the navy as a midshipman in 1800, and served under Commodores Rodgers and Decatur. In July, 1813, he was promoted to the rank of lieutenant, in which grade he performed much arduous service, particularly upon the coast of Africa, and in protection of commerce from pirates in the West Indies in the years 1821 and 1822. In March, 1826, he was promoted to be commander, and in 1837 to be captain. Beside serving a great deal on foreign stations, he took an important part in the organization of the steam naval service, and conducted a series of ordnance experiments. In 1838 he was ordered to Europe on special service connected with dock yards and lighthouse administration. He subsequently commanded the navy yard at Brooklyn, and the squadron on the coast of Africa, the frigate Macedonian bearing his flag. In 1846 he was appointed second in command of the squadron in the gulf of Mexico with orders to hoist a red broad pennant in the steamer Mississippi; and in March, 1847, succeeded Commodore David Conner in the command of that squadron, which he held until the close of the Mexican war, accomplishing the reduction of the whole gulf coast of Mexico, and occupying every point through which supplies could be sent into the enemy's country. All the operations of this important command were conducted by Commodore Perry with skill, and the most indomitable energy and perseverance. In March, 1852, he was appointed to the command of the Japan expedition, and negotiated a treaty with that exclusive government, which opened the way to the intercourse which now subsists between Japan and the United States. The interesting and important results of this expedition have been published in 3 vols. 4to. (Washington, 1856), and in two abridgments. He returned to the United States in 1856, and died while on special service growing out of the expedition.

PERRY, Oliver Hazard, an American naval officer, born in Newport, R. I., in Aug. 1785, died at Port Spain, island of Trinidad, Aug. 23, 1819. He entered the navy as a midshipman, April 7, 1799, and was first in active service under the command of his father, Capt. C. R. Perry, in the frigate General Greene, 28, which performed an active and important cruise on the West India station during 1799 and 1800. In 1802 he served in the Mediterranean in the frigate John Adams, Capt. Campbell, and again on the same station in 1804–'6 in the Constellation frigate and Nautilus schooner. In Jan. 1807, he was promoted to the rank of lieutenant, and in 1809 was in command of the schooner Revenge, 14, and cruised actively upon the coast of the United States until Jan. 1811, when the Revenge was wrecked upon Watch Hill reef near Stonington, Conn. A court of inquiry ascribed the accident to tides and thick weather, acquitting Lieut. Perry of all blame. At the opening of the war of 1812, Perry was in command of a division of gun boats at Newport, R. I., and in Feb. 1813, he was transferred, at his own request, with a portion of his officers and men, to the command of Commodore Isaac Chauncey on the lakes. In the following March he was ordered by Commodore Chauncey to superintend the equipment of a naval force on Lake Erie, and while thus employed at the port of Presque Isle (now Erie), he was called away for the moment to aid in an attack upon Fort George. He coöperated gallantly and ably with the army in that affair, at the head of a body of seamen. In Aug. 1813, Perry, taking advantage of the momentary absence of the British squadron which had been watching him, succeeded in getting the force which he had equipped out of the port by lifting the larger vessels on camels, and, though very deficient in officers and men, and imperfectly equipped, brought the British squadron to an engagement on Sept. 10, which resulted in the complete success of the American arms. (See ERIE, BATTLE OF LAKE, vol. vii. p. 270.) After this brilliant and important action, which raised Perry to the highest naval renown, he coöperated with the army of Gen. Harrison by assisting in regaining possession of Detroit, in transporting troops, and serving at the battle of the Moravian Towns. At the close of the operations of 1813, he gave up his command. Congress bestowed a gold medal upon him for his services, and he was promoted to the rank of captain, his commission being dated Sept. 10, 1813, the day of the battle. High civic honors were paid him wherever he went, and more than 40 counties, towns, and villages have been named after him in different parts of the Union. In Aug. 1814, he was appointed to the Java, 44, a new frigate under equipment at Baltimore; but as the Chesapeake was closely blockaded, it was impossible to get her to sea, and Perry, with his officers and men, was actively employed in annoying the British squadron in their descent of the Potomac from Alexandria, and in the defence of Baltimore. After peace was proclaimed he cruised in the Java upon the coast of the United States, and in the Mediterranean until Jan. 1816. In March, 1819, he was appointed to the command of a squadron for the coast of Colombia, and sailed from Annapolis on June 7 of that year in the John Adams, 24, which bore his flag. In July he ascended the river Orinoco in the schooner Nonsuch (one of the vessels of his squadron) to Angostura, the capital of Venezuela, where he was engaged several days in the transaction of business with the government. On leaving the river he was seized with yellow fever, which terminated fatally the day the Nonsuch arrived at Port Spain. A few years later his remains were transferred in a ship of war to his native place. On Sept. 10, 1860, a marble statue by Walcutt was erected, with imposing ceremonies, at Cleveland, Ohio, to the memory of Commodore Perry, near the scene of his great battle, by the citizens of that place.

PERSEPHONE. See PROSERPINE.

PERSEPOLIS (Gr., "city of the Persians;" Pers. *Istakhar*), one of the ancient capitals of Persia. It stood 35 m. N. E. of Shiraz, on a spacious plain now called Merdasht, near the confluence of the Medus and the Araxes (now Pulwan and Bendemir). The plain is naturally one of the richest and most beautiful in the world, and is surrounded on all sides by lofty mountains rising from the verdant level like islands from the ocean. At the foot of one of these mountains, which projects somewhat beyond the line of the range into the plain, is a high terrace of the most massive Cyclopean masonry, extending N. and S. about 1,500 feet, and from E. to W. about 800 feet. The whole however is not one level platform, but is divided into three great terraces, of which that to the S. is the smallest and lowest, rising only 20 or 25 feet from the plain, with a breadth of 180 feet. The great centre platform is nearly 800 feet square, and rises 45 feet above the level of the plain. N. of this is the third platform, about 550 feet in length and 35 feet in height. On the northern and central platforms are grouped various ruined edifices, which appear to have been palaces or temples, and are all that remain of Persepolis. The principal features they present are tall, slender, isolated columns, stately portals, and ruined walls covered by hundreds of sculptured figures of men and animals. The chief ruins are those of the great hall of 100 columns, the Chehil Minar or great hall of Xerxes, the palace of Xerxes, and the palace of Darius. The stairs which lead to these edifices are among the most remarkable of the architectural features of Persepolis, and are peculiar to the place. The finest of these is that which leads from the plain to the northern terrace. It consists of two double flights, each 22 feet wide, the steps rising only about 3½ inches, while they are nearly 15 inches deep, the ascent being so easy that persons on horseback go up and down without difficulty. Its whole style is colossal, as many as 6 steps being cut in one block of marble, and the stones of the perpendicular walls being also of immense size. There are several stairs leading to the summit of the terraces, most of which are ornamented with sculptures, representing colossal warriors with spears, gigantic bulls, combats with wild beasts, and processions bringing tribute. There are also many inscriptions on the stairs and the buildings, in three different classes of cuneiform writing, of which the Zend always occupies the prominent place. These inscriptions have been read by Lassen and Rawlinson, who have thus ascertained that all the most important works were constructed by Darius Hystaspis and Xerxes (521–465 B. C.). Of the largest of these structures, the great hall of Xerxes, or the Chehil Minar as it is called by the modern Persians, Fergusson, the eminent writer on architecture, says: "It was not only one of the largest but one of the most splendid buildings of antiquity. In plan it was a rectangle of about 300 feet by 350, and consequently covering 105,000 square feet (2½ acres); it was thus larger than the hypostyle hall at Karnak, or any of the largest temples of Greece or Rome. It is larger, too, than any mediæval cathedral except that of Milan; and although it has neither the stone roof of a cathedral, nor the massiveness of an Egyptian building, still its size and proportions, combined with lightness, and the beauty of its decorations, must have made it one of the most beautiful buildings ever erected, and both in design and proportion far surpassing those of Assyria, though possessing much of detail or ornament so similar as to be almost identical in style."—At the distance of 1½ miles from the ruins of Persepolis a valley about 2 miles in width opens into the plain of Merdusht; and in the gorge of this valley, just where it opens on the plain, stood the city of Istakhar, so famous in oriental story, and according to the Persians the oldest city in the world. Darius, soon after he ascended the throne, seems to have removed the seat of government from Pasargadæ, the old capital of Persia, to Istakhar, and to have commenced in the southern suburb of that city the building of the palaces and court quarter to which the Greeks gave the name of Persepolis. After the destruction of the Persian monarchy by Alexander (who is reported by some of the Greek historians to have set fire to the palaces of Persepolis at the instigation of Thaïs the courtesan, a statement not corroborated by the appearance of the ruins, which show no traces of fire), the city shrunk back to its original dimensions, and under its native name of Istakhar became celebrated in the subsequent history of Persia, and remained an important place to a comparatively recent period.—See Fergusson's "Palaces of Nineveh and Persepolis Restored" (London, 1851).

PERSEUS, a Grecian legendary hero, the son of Jupiter and Danaë. Acrisius of Argos, the father of Danaë, having been warned by an oracle that the son of his daughter would cause his death, shut her up in a strong room; but Jupiter came down through the roof in the form of a shower of gold, and became by her the father of Perseus. Acrisius caused the mother and child to be placed in a chest and cast adrift at sea. The chest floated to the island of Seriphus, where Perseus was brought up by King Polydectes; but the latter, anxious at last to get him out of the way that he might gratify his passion for Danaë, sent him to fetch the head of the gorgon Medusa. Having obtained from the nymphs winged sandals to bear him through the air, a magic wallet, and the helmet of Pluto which rendered him invisible, from Mercury a sickle, and from Minerva a mirror in which he could see the reflection of Medusa, since a sight of the monster herself would change him to stone, he accomplished his errand while the gorgons were asleep. On his way back he saved Andromeda from being devoured by a sea monster, and married her. (See ANDROMEDA.) Arriving at Seriphus, he found his mother pursued by the violence of Polydectes, whom he metamorphosed with all his guests into stone by means of the gorgon's head. He then returned with his wife and mother to Argos, and Acrisius, remembering the oracle, fled to Larissa. Perseus, following him in order to persuade him to return, is said to have accidentally killed him with a discus in the course of the games which the king of Larissa was celebrating in Acrisius's honor. Unwilling to return to Argos, he exchanged that kingdom with Megapenthes for the government of Tiryns. He presented the gorgon's head to Minerva, who placed it on her shield.

PERSEUS, or PERSES, the last king of Macedon, reigned from 178 to 168 B. C. He was the son of Philip II., or as others call him V., and before coming to the throne served with some distinction in the army. He persuaded his father to put to death a younger son, Demetrius, whom he suspected of entertaining ambitious designs. Immediately upon his accession he confirmed the treaty concluded by his father with the Romans, but began secretly to prepare for war, and endeavored to form alliances with the states of Greece. Hostilities were hastened by an attempt of Perseus to assassinate Eumenes, king of Pergamus, who had reported to the senate the warlike preparations of the Macedonians. The senators pronounced Perseus an enemy of the republic (172 B. C.), and the consul P. Licinius Crassus was sent with an army to invade his dominions. He met the Macedonians in Thessaly, where two slight engagements were fought (171), Perseus winning one and Crassus the other. The war lasted 4 years, with disadvantage on the whole to the Romans; but at last the avarice of Perseus alienated his allies, and on June 22, 168, he was signally defeated near Pydna by the consul L. Æmilius Paulus. He took refuge in Samothrace, where he soon afterward surrendered, and in the following year was carried to Rome to adorn the triumph of the victor. Æmilius however treated him kindly, and, when he was afterward cast into a dungeon by order of the senate, procured his removal to a place of honorable captivity at Alba, where he passed a few years and died, either of voluntary starvation, or, according to a less probable account, of enforced want of sleep. He left two young children, Alexander, who is said to have become a scribe to the municipality of Alba, and a daughter. His younger brother and adopted heir, Philip, died in captivity.

PERSIA (the native name of which is Iran), a country of Asia, bounded N. by Russian Armenia, the Caspian sea, and Toorkistan, E. by Afghanistan and Beloochistan, S. by the Indian ocean, S. and S. W. by the Persian gulf, and W. by the Turkish empire. It lies between lat. 25° and 40° N. and long. 44° and 62° 30′ E.; greatest length from N. W. to S. E. about 1,000 m., average breadth about 600 m.; area, about 500,000 sq. m.; pop. variously estimated at from 5,000,000 to 10,000,000. It is divided into 25 provinces. In the N. are Ghilan, Mazanderan, and Astrabad; in the W., Azerbaijan, Ardalan or Koordistan, Luristan, and Khoozistan; in the S., Fars, Laristan, and Kerman; in the E., Yezd, Tabas or Tubus, Ghayn and Birjoon, Toorshiz, Meshed, Damghan, and Semnoon and the Great Salt desert. These eastern provinces collectively constitute Khorassan. Central Persia or Irak-Ajemee comprises the provinces of Khamsah, Kasbin, Teheran, Hamadan, Koom, and Ispahan. The principal cities are Teheran, the capital, Ispahan, the former capital and still the largest city of the kingdom, Tabriz, Ooroomeeyah, Hamadan, Shuster, Kashan, Reshd, Balfroosh, Astrabad, Meshed, Nishapoor, Yezd, Bushire, Shiraz, Lar, and Kerman. Several of these cities are among the most famous of the East for wealth and magnificence, but the visitor from Europe or America is always greatly disappointed by their appearance, which at the present time offers little to the eye of the beholder but ruins, filth, and misery. The view of a Persian city from the exterior is usually monotonous and uninteresting. The low and irregular houses, built mostly of mud, resemble heaps of dirt more than human habitations. The dwellings of even the rich and powerful seldom exceed a single story, and are shrouded from sight by high blank walls. The only public buildings are mosques, colleges, and caravansaries, most of which are as mean as the dwellings. There are not many minarets or domes of magnitude, and few of these exhibit either elegance or grandeur. The only relief to the monotony of the view is afforded by the gardens, which are planted with forest and fruit trees, and to a greater or less extent are seen near all the towns of Persia. The traveller usually approaches these cities through a narrow and dirty lane bounded by decayed mud walls, and must pick his way among heights and hollows, the fragments of old buildings, and the pits which have supplied the clay for new ones. Entering the dilapidated gateway, he finds himself in a mean-looking bazaar, or perhaps among heaps of rubbish as filthy and confused as those outside. "Any thing more dismal can hardly be conceived," says Lady Sheil, describing her entrance into Tabriz in 1849. "The images of youth are not easily effaced; and the 'Arabian Nights' and 'Lalla Rookh' will hold their place in the memory whether it will or not. But once inside the gate of a Persian city, the charm is dissolved, the magician's wand is broken, and reality takes the place of romance, which is destroyed for ever. Half the city seemed depopulated; there were large spaces wholly vacant, with deep excavations on either hand, from which the earth had been dug to build houses. Dead dogs, and here and there a dead horse half eaten, offended more than one sense. The houses were frightful. Constructed of brown unburnt bricks, looking exactly like mud, and without a single window to the streets, they presented a most gloomy aspect. This is a general picture of a Persian town, and be it remembered that Tabriz is one of the best and richest cities in the whole kingdom." The wretched appearance of the outside of a Persian house, however, is not a just indication of the state of the interior. The dwellings are generally comfortable, and those of the richer classes are often of great size and contain very handsome and commodious apartments.—The principal ports of Persia are Balfroosh on the Caspian sea and Bushire on the Persian gulf. The other ports are of little consequence. There is a marked deficiency of good harbors on both the N. and S. coasts. The deficiency of rivers in so vast a country is still more remarkable; there is scarcely a navigable stream in the whole kingdom. The largest rivers are the Karoon, which flows into the Shat-el-Arab or United Tigris and Euphrates, the Aras or Araxes, and the Safid Rud or White river, which flow into the Caspian. While the greater part of Persia suffers from want of water, the northern provinces bordering upon the Caspian sea are as remarkable for the multitude of their streams as the rest of the country is for its aridity; but they are for the most part mere torrents, full in winter and nearly drying up in summer. A striking characteristic of the topography of Persia is the frequent occurrence of salt lakes, of which that of Ooroomeeyah is the largest. It is in the province of Azerbaijan, between lat. 37° 5′ and 38° 15′ N., at the height of 4,300 feet above the sea, and is 80 m. in length and 20 in breadth, with an average depth of 12 feet. It is fast drying up, and is bordered by large tracts covered with salt, with which its waves are intensely impregnated.—Persia has been called a country of mountains, but it is for the most part rather a high table-land, rising 3,000 or 4,000 feet above the sea, bounded on all sides except the E. by lofty ranges, preëminent among which is the mighty chain of the Elbrooz. This great range, striking off from the Caucasus, enters the kingdom at the N. frontier, which it covers with a gloomy mass of black peaks, and from Ardebil runs parallel with the S. shore of the Caspian sea to Astrabad. Thence it passes in an easterly direction to the N. of Meshed into Afghanistan and Toorkistan. A branch of the Elbrooz called the Sahund mountains strikes off from Lake Ooroomeeyah in a N. E. direction, and spreads in various clusters through Azerbaijan. Another branch is the Zagros range, which divides ancient Assyria from Media, and, splitting into a confused mass of ridges and valleys in Koordistan, continues southward under the appellation of the Luristan and Buchtiaree mountains along the western borders of the table-land, and after traversing Fars stretches along the Persian gulf at various distances from the sea as far as Gombroon near the S. E. corner of the kingdom. North of the Elbrooz and between it and the Caspian are the provinces of Ghilan, Mazanderan, and Astrabad, which are low, level, well watered, and fertile. The region between the S. boundary of the plateau and the Persian gulf and the Indian ocean is called the Dushtistan or "level country," and, with a breadth varying from 50 to 150 m., exhibits a succession of sandy wastes, occasionally relieved by a plantation of date trees and a few patches of cultivation in such places as are blessed with a rivulet or a copious well. From the principal ranges we have mentioned run a multitude of branches that cover the surface of Persia with a network of rocky lines. Among them are to be found plains and valleys which wherever moisture abounds are fertile, but where water is absent are deserts of sand or salt. The valleys at the southern foot of the Elbrooz are rich with verdure throughout the year, and on the slope of the mountains N. of Teheran is a tract 20 m. in length covered with gardens and groves and bearing the name of Sham'a-i-Iran, or "light of Persia." In the central provinces the valleys are generally level. In Azerbaijan they lie between a succession of eminences. Koordistan in the N. is little more than a cluster of mountains with an almost Alpine climate.—Salt deserts occupy a great part of the surface of Persia, and are many of them covered by a saline efflorescence which glitters vividly in the sunshine. The Great Salt desert, the most extensive of these tracts, lies in the centre of the country, and is 400 m. in length and 250 m. in breadth. The nature of this desert varies in different places. In some the surface is dry and produces a few plants, such as prefer a salt soil; in others it is marshy, and in others the earth is covered with a crust of salt. Over considerable tracts sand predominates, which in some places is so light and impalpable as to be extremely dangerous to travellers, who are sometimes overwhelmed and buried in the drifts raised by the wind. Here and there this desert is broken by inhabited oases, though by none of very great extent. The general aspect of the country is arid and dreary, the mountains being merely masses of bare gray rock, rising abruptly from the plain and unrelieved by trees or shrubs. The plains, even where they are not absolutely desert, are chiefly of barren gravel or clay, and for 10 months of the year are parched with heat. The only trees to be seen are in the gardens of villages or on the banks of the few streams where they have been planted for timber. The provinces on the Caspian sea, however, are exceptions to the general dreariness, and are as beautiful as wood, water, and grand and varied mountain scenery can make them.—Comparatively little is known of the geology of Persia. The Elbrooz mountains are supposed to possess a primitive character. Porphyry, colored with chlorite, and compact feldspar with green earth, are found in abundance in the torrent beds, with occasionally granite and mountain limestone. The branches of the Elbrooz, however, lose this primitive character, and may be generally described as follows: calcareous substances stretch along their eastern skirts; on their southern acclivities schistose rocks appear; clay intermingled with quartz occupies the middling and higher regions; while granite composes the lower tracts of their northern aspects. Traces of volcanic action are to be found in several parts of the Elbrooz range; the peak of Demavend, the highest of its summits, which, according to the latest measurements, rises 21,500 feet above the sea, is undoubtedly an extinct volcano; and the frequent earthquakes in the vicinity of the mountains indicate the existence of subterranean fires over a wide-spread region. The most interesting geological feature of the Elbrooz mountains is the turquoise mines, situated about 40 m. W. of Nishapoor. The base of the ridge where they lie is composed of white, gray, yellow, red, or brown porphyritic earth, interspersed with veins of brilliant red, disposed in hillocks, on the top of which rest beds of limestone or porphyritic conglomerates. The mines are opened in beds of porphyritic earth or rock, deeply tinged with iron, through which the turquoise is disseminated in veins, nodules, and irregular masses. Being full of flaws, it possesses no great mercantile value. The Sahund mountains exhibit great masses of calcareous conglomerate resting on a base of granite. Their summits are composed of porphyry, sometimes containing crystals of glossy feldspar and hornblende. Some of the lower hills intervening between these mountains and Tabriz are covered with blocks and pebbles of a dark blue rock containing calcareous matter. Iron is abundant in Persia, though it is little manufactured. Copper, lead, and antimony also abound, and salt, sulphur, and naphtha are produced in great quantities. Excellent coal is found in the Elbrooz, and also valuable varieties of marble.—The climate of Persia is so much modified by the elevation of the surface that, according to the traveller Kinneir, one may pass in a few hours from the air of Montpellier to the cold of Siberia. Demavend and the other highest peaks of the Elbrooz are covered with snow throughout the year. The winter on the great plateau is long and severe, and heavy storms of snow are common at this season. The heat of summer is intense. The English traveller Morier states that at Shiraz after the middle of June the thermometer was scarcely ever under 100° in the shade, and frequently rose to 110°. In the low lands on the Persian gulf the heat of summer is increased by the winds from the sandy deserts with which this region abounds, but the winter and spring are delightful. But notwithstanding the great extremes of the climate of Persia, and the sudden transitions from heat to cold, it is very healthy, with the exception of the low coasts of the Caspian, where from the superabundance of moisture and of vegetation fevers prevail. Throughout the greater part of the country rain seldom falls, and the air is dry and the atmosphere so clear that polished metal may be exposed to it without becoming rusted.—Notwithstanding the generally barren appearance of the land, the cultivated soil wherever it is supplied with moisture is exceedingly fertile. Small streams and canals are valued at high rates and produce extraordinary rents. Fraser mentions a canal employed to irrigate a fruit garden of which the water rent was nearly $10,000. The principal products of Persian agriculture are wheat, barley, and other grains, the wheat being as fine as any in the world. The vine flourishes in several provinces, and the grapes and the wine of Shiraz are celebrated in the poetry of the East. The rich provinces on the Caspian produce the mulberry in great abundance, and include silk and sugar among their chief staples. Cotton is produced in sufficient quantity to supply the wants of the people; and in Feb. 1861, the Persian ambassador at London stated in a published letter that sufficient cotton could be grown in the southern provinces to supply the wants of Europe. Among the other useful products of the soil are gum tragacanth, assafœtida, saffron, henna, madder, opium, indigo, and tobacco. Fruits are grown in great perfection and abundance. Dates are largely used as food, and those of Dalaki in the province of Fars are particularly celebrated for richness and flavor. Pomegranates, shaddocks, limes, apples, pears, apricots, and walnuts grow in perfection everywhere, and oranges on the low lands. The melons are the largest and finest in the world. Though trees are very scarce in the greater part of Persia, the mountains of the Caspian provinces are covered with forests of valuable timber, including oak, elm, beech, walnut, and boxwood. The licorice plant is found in profusion on the plain of Merdusht and near Shiraz. A plant resembling hemlock, with a rich dark green verdure and from 5 to 6 feet high, yields the gum ammoniac. Among the vegetables, carrots, turnips, cabbages, and beets are common. Flowers grow in great luxuriance, and there are many beautiful species native to the country. Wild animals abound in the desert, among them the lion, tiger, wolf, jackal, hyena, fox, wild boar, wild ass, wild sheep, and antelopes and deer in great variety. The wild sheep is strong and courageous, and has large, crooked, and twisted horns. The wild ass is shy and very fleet, outstripping the best horses. Among the domestic animals, the most common are the camel, cow, sheep, goat, ass, horse, and mule. The native horses are large and strong, and the breed has been much improved by intermixture with the Arab. They are remarkable for their powers of endurance, and some of them will carry their riders for a week together at the rate of 100 miles a day. Those of the best quality frequently sell for $1,000, and are used for plundering expeditions. From the prevalence of hot and arid deserts, camels are preferred as beasts of burden, though mules are much used among the mountainous regions. From the scarcity of trees in Persia birds are rare. Pheasants are found on the coasts of the Caspian, and pelicans and bustards on the shores of the gulf. Among the song birds are blackbirds, thrushes, and the bulbul or nightingale. The rivers contain few fish, but valuable fisheries are carried on upon the shores of the gulf and the Caspian.—The population of Persia consists of two very distinct classes, the settled inhabitants and the tribes who are called Eels, a Turkish word signifying clans. Some of these tribes have become stationary, and have devoted themselves to agriculture, though still preserving their union as tribe men; but the rest of them are wanderers, who with their families and flocks change their quarters each summer and winter in search of pasture to grounds more or less distant belonging to the tribe, and which cannot be encroached on by other clans. A clan or *eel* is ruled by its *sheik* or chief and by the heads of the different *teerehs* or branches of the tribe. To these chiefs the whole tribe is devoted with a patriarchal loyalty like that of the highlanders of Scotland to the heads of the clans. The tribes comprise 4 races, viz., Toorks, Koords, Leks, and Arabs. The first are invaders from Toorkistan, who from time immemorial have established themselves in Persia, and who still preserve their language. The Koords are not numerous in Persia, the greater part of the nation living in Turkey. They are supposed to be of Persian descent, and speak a dialect of the Persian language. The Leks are of genuine Persian blood, and are supposed to be descendants of the ancient inhabitants of the country. The Arab Eels are descended chiefly from the Mohammedans who conquered Persia in the 7th century, but they have lost their original language and become Persians both in speech and appearance. The Eels generally live in tents, and are distinguished for courage, manliness, and independence. They are however inveterate robbers, and their turbulence has for sev-people. Every morning the shah holds a public levee, at which complaints are heard and justice administered in the form of reward or punishment. His principal minister or grand vizier is a personage of great power and influence, and receives a salary of 42,000 tomans, equivalent to $100,000, annually; but he is always exposed like the meanest subject to capricious punishments, and holds his life at the mercy of the monarch. Beside the chief minister there are secretaries who preside over various departments of state and finance. The law, as in all Mohammedan countries, is founded upon the Koran and partly on traditions. The civil law is administered by the mollahs or priests, whose decisions are generally affected by bribes or personal considerations. Criminal cases are referred to courts appointed by the state. The ordinary punishments are fines and floggings. Capital offences are punished by strangling, decapitation, or stabbing, and great offenders are sometimes tortured to death. The revenue of the shah amounts generally to $8,000,000 or $9,000,000, and is principally derived from a tax on land. There are also taxes on gardens, vineyards, shops, horses, animals, and various kinds of goods, and in some provinces a poll tax on all males above 14 years of age. Small as the revenue is, considering the size of the kingdom, such is the cheapness of every thing in Persia that it is generally sufficient to meet the expenditures. A large army is maintained, part of it disciplined and officered by European adventurers. The regular infantry is nominally rated at 100,000 men, but does not in reality exceed 70,000. The best trained portion of the force is the artillery, which numbers 6,000 men. This arm of the service was found to be very efficient in 1860, in several severe conflicts with the nomadic tribes whose power has been broken by the present shah. The cavalry number from 30,000 to 50,000, and are well armed and mounted. They are said to be able to encounter in the field the Russian Cossacks, and to be superior to the Turkish irregular horse.—The earliest history of Persia, as it is related by the poet Firdusi, the only native historian of ancient times, is a mass of legends, mostly purely fabulous, though some doubtless have a basis of reality, in which figure the dynasties of Mahabad, of the Jaianians, of Shah Kaliv, and of Yessan, which seem to have been altogether mythical. Next succeeded the Pishdadyan dynasty, founded by Kaimurs, of which the most celebrated kings were Tahmuras, the reputed founder of Ispahan; Jamshid, the founder of Istakhar, a monarch much renowned in oriental story; Afrasiab I. and Afrasiab II., the latter of whom was defeated and dethroned by the national hero Rustam, who placed on the throne Kai Kubad, the founder of a dynasty of which the succeeding monarchs were Kai Kaus, Kai Khusrau, Luhrasp, Gashtasp, Bahman or Ardashir Dirazdast, Dara I., and Dara II. From the researches of recent European scholars it appears, however, that the true history of Persia, so far as it is authentically known, is as follows. At a very remote period a great Aryan migration from beyond the Indus entered Persia and Media, and continued for some centuries. At length, in the 9th century, that part of the Aryan emigrants which afterward formed the chief element of the Median nation encountered the Assyrians, who were then a great power on the Tigris, and after a long struggle were subdued by the Assyrian king Sargon in 710 B. C. About 633 the Medes led by Cyaxares revolted, and, having taken Nineveh in 625, laid the foundation of the Median empire. Cyaxares is the Kai Kabad of the native poets. To him succeeded Astyages, after whom reigned another Cyaxares, according to some the Darius of the book of Daniel, and the Kai Kaus of the Persians. His successor, Kai Khusrau, is the Cyrus of the Greeks, according to whom he was the chief of the tribe of Persians who inhabited Persis, the modern Fars, and were subjects of the Medes. About 559 Cyrus was acknowledged as sovereign of the united nation of Medes and Persians, in which henceforth the Persians had the predominance. He conquered Babylon, and founded a great empire. At his death in 529 he was succeeded by his son Cambyses, who added Egypt and a great part of northern Africa to the empire. During a tyrannical reign of 7 years he committed great outrages, not only on the Egyptians, but on the principal men of Persia. Among others, he put to death on suspicion of treason his brother Bardes, whom the Greek writers erroneously call Smerdis. At length in 522, while he was yet absent in Egypt, the magians or priestly aristocracy brought forward one of their own number named Gomates, whom they imposed upon the people as the murdered Bardes, to whom he bore some personal resemblance. The people, disgusted with the tyranny of Cambyses, readily accepted the usurper as king; and Cambyses, on learning the news of the revolt, committed suicide, according to the Behistun inscription, or according to the Greek writers died from a wound which he accidentally gave himself. After a reign of 8 months the usurper was detected and put to death by a conspiracy of Persian chiefs, one of whom, Darayavush, the Darius Hystaspes of the Greeks, was made king. Darius reigned 36 years, and considerably enlarged the empire, making extensive conquests in the east in the regions bordering on the Indus, and in the west carrying his arms into Europe and overrunning Thrace and Macedonia. In an attempt to subdue the Greeks his forces were completely routed at Marathon in 490, and 4 years afterward he died, and was succeeded by his son Xerxes, who renewed the invasion of Greece in person, and at first with a certain degree of success, but finally lost both his immense fleet and army at Salamis, Platæa, and Mycale, and was assassinated in 465. Six sovereigns bearing the names of Artaxerxes, Xerxes, and Darius succeeded, with the last of whom, Darius Codomanus, the Dara II. of the Persian historians, terminated the dynasty of Cyrus. Persia, which for two centuries had been the leading power of the world, with a dominion extending over an area of 3,000,000 or 4,000,000 square miles, and a population probably of several hundred millions, submitted to Alexander the Great, who invaded it in 334 with an army of 35,000 Greeks, and, after defeating the Persians in the great battles of the Granicus, Issus, and Arbela, became on the death of Darius (who was murdered in his flight from Arbela) the undisputed master of the empire. After the death of the Macedonian conqueror, his generals for several years disputed by force of arms the possession of his Asiatic dominions; but about 307 Seleucus Nicator became master of Persia, which he transmitted to his successors Antiochus Soter and Antiochus Theos. In the reign of the latter, about 256, the Parthians, a tribe inhabiting the north of Persia, who from remote times had been subject to the Persians, revolted under Arsaces and founded the third Persian dynasty, the Arsacidæ of the classic writers, the Ashkanians of the Persians, by whom Arsaces was called Ashk. This dynasty lasted till A. D. 226, under 34 monarchs, of whom little is authentically known, this period of nearly 5 centuries being the most obscure in the history of Persia. Their capitals were Seleucia and Ctesiphon, and the most celebrated events of their annals were their wars with the Romans, beginning about 53 B. C. with the invasion of their empire by Crassus, whose army was cut to pieces and he himself slain. Several long contests ensued, in which the Parthians were sometimes victorious and sometimes defeated, till in the beginning of the 3d century the victories of the Roman generals threw Parthia into such confusion that Artaxerxes, or Ardshir as he is called by the native historians, claiming to be a descendant of the ancient royal family of Cyrus, revolted and overthrew and put to death Artabanus V., the last of the Arsacidæ, and proclaimed himself sovereign of Persia with the title of Shahanshah or "king of kings," which is still assumed by the Persian monarchs. He also restored the ancient religion of Zoroaster and the authority of the magi, which had fallen into discredit. The dynasty which he founded, under the name of the Sassanidæ, consisted of 28 or 29 monarchs, and continued upward of 400 years. Among the most famous of these kings were Sapor or Shahpur, the son of Artaxerxes, who carried on a successful war with the Romans, in which he defeated and took prisoner the emperor Valerian; Sapor II., whose reign began with his birth, lasted 71 years in the 4th century, and was marked by bloody wars with the Roman emperors Constantius and Julian, the latter of whom was defeated and slain in the contest; Varanes V. or Bahram Gour, who was celebrated for his munificence and generosity, and for his successful repulse of a Tartar invasion; and Chosroes or Khosru Nushirvan, who is considered by the Persians a model of justice, generosity, and sound policy, and who was both a great ruler and great conqueror, compelling the emperor Justinian to a disgraceful peace, and advancing the Persian arms to the Mediterranean on the west, beyond the Oxus and the Indus on the east, and into Arabia on the south. His reign of 48 years, from A. D. 531 to 579, was the golden age of modern Persia, according to the native poets and historians. His grandson, Khosru Parviz or Chosroes II., who succeeded him after an interval of two short reigns, is also famous for his conquests, which extended through Syria and Palestine into Egypt, and even to Tripoli and Carthage, while at the same time and subsequently his victorious armies were for 12 years encamped near Constantinople. He is still more celebrated in the East for his luxury and magnificence, and oriental history abounds in tales of his palaces, his superb thrones, his immense treasures, his unrivalled poets and musicians, his 50,000 Arab horses, and his 3,000 beautiful women, the most lovely of whom was Shirin or Irene, a Greek and a Christian, whose beauty and whose love form the subject of a thousand poems. His favorite residence was Dastagerd, E. of the Tigris, and about 60 m. from Ctesiphon. The latter years of his reign were unfortunate and inglorious. The emperor Heraclius, suddenly rousing from the sloth and self-indulgence which had hitherto marked his life, invaded Persia with a powerful army, and in 6 years Chosroes was stripped of all his foreign conquests, his famous palace at Dastagerd was plundered and burned, and finally he himself was dethroned and murdered by his eldest son Siroes or Sheruyeh in 628. From this time till the accession of Yezdegird III. in 632, Persia was given up to anarchy. The Mohammedan Arabs were already attacking the empire, and Yezdegird in vain attempted to stem the tide of armed fanatics that poured from the adjacent deserts. On the plains of Nahavand in 641 a great battle, in which 100,000 men are reported to have fallen, decided the fate of Persia. The defeated monarch, flying from the field, took refuge in his eastern provinces, where for several years he wandered a fugitive till in 651 he was murdered by a miller, and with him ended the line of the Sassanian kings and the religion of the magi. After horrible massacres the people, persuaded by the sword, embraced Mohammedanism, only a small, obscure, and persecuted remnant daring to adhere to the ancient faith of Persia. (See Guebres.) For the next two centuries Persia was subject to the caliphs. But in 868 an adventurer named Soffar, who had been a pewterer and afterward a bandit, gathered a native force and expelled the viceroys of the caliph. He founded a dynasty known as the Soffarides, of which three more princes maintained a precarious authority, till in the beginning of the 10th century Persia was divided between the families of Samani and Dilami, the first of which reigned over eastern Persia and Afghanistan, and the second over the rest of the country. Under these dynasties Persia fell beneath the yoke of the Seljooks, and was ruled by Togrul Beg, Alp Arslan, and Malik Shah, all of whom were conquerors greatly celebrated in oriental history. Their dynasty declined and perished in the 12th century, and after a long period of anarchy Persia was overrun and conquered by the Tartars led by Hulaku Khan, the grandson of Genghis, who established the seat of his empire at Maragha in Azerbaijan. The next important event in the history of Persia was the conquest and devastation by Tamerlane toward the end of the 14th century. Under his successors civil war almost continually prevailed, until in the beginning of the 16th century Ismael, a descendant of a famous saint, Sheik Suffee, succeeded in making himself master of the kingdom and founded the Suffavean dynasty. He died in 1523, and was succeeded by his son Tamasp, whose reign of 53 years was eminently prosperous. Abbas, the successor of Tamasp, was a still greater sovereign, though to his own family he proved a sanguinary tyrant. After his death in 1628 the Suffavean dynasty gradually declined, and was at length overthrown by the Afghans, who conquered Persia in 1722, and ruled it for 7 years with horrible tyranny, till they were expelled by the celebrated Nadir Shah, who in 1736 himself ascended the throne. His reign was memorable for success over foreign enemies and for bloody cruelty to his family and people. After his death a series of revolutions occurred from conflicting claims to the throne, and order was not fully restored till the close of the 18th century, when Agha Muhammad Khan became shah, and partly by policy and partly by cruelty succeeded in quelling the spirit of rebellion. His successors were Fath' Ali Shah, who died in 1834, Muhammad Shah, who died in 1848, and Nasureddin, the present shah. The principal events in their reigns have been wars with Russia, the first of which terminated in 1813 and the second in 1828, both of them disastrously to Persia, which lost successively the provinces of Georgia, Mingrelia, Erivan, Nakkshivan, and the greater part of Talish, the Russian frontier being advanced to Ararat, and the left bank of the Aras; and a war with England, which began in 1856 by a quarrel with the English minister at Teheran about a woman with whom he was accused of living in adultery, and terminated March 4, 1857, after repeated victories of the English troops in the south of Persia under the command of Generals Outram and Havelock.—See Sir J. Malcolm's "History of Persia" (2 vols., London, 1815); "Historical and Descriptive Account of Persia," by James B. Fraser (Edinburgh, 1834; New York, 1836); "Glimpses of Life and Manners in Persia," by Lady Sheil (London, 1856); "Outram and Havelock's Persian Campaign" (London, 1858). The novels of James Morier, "Hajji Baba," "Zohrab," "Ayesha, the Maid of Kars," and "The Mirza," are excellent illustrations of Persian society, character, and scenery.

PERSIA, Language and Literature of. In treating the Persian language we have to consider not only the modern Persian, the spoken and written dialect of the Persian people during the past 9 centuries, but also those more ancient idioms once prevailing in or near the same territory, which are most intimately connected with this modern language, as older forms of it. We shall thus have to treat of 5 dialects, viz.: 1, the Achæmenian Persian, or Old Persian, the language of the cuneiform inscriptions; 2, the Avestan, Zend, or Old Bactrian, the language of the Zendavesta, the Bible of the Zoroastrian religion; 3, the Huzvaresh or Pehlevi; 4, the Parsee; 5, the modern Persian itself. These form together a well marked group of closely related dialects, classifiable as the Iranian branch of the Aryan division of the Indo-European family. The name Aryan is sometimes applied to the whole family, but is much more properly restricted to that principal division of it which includes the Indian and the Persian languages, or the Sanscrit and its dialects and derivatives on the one side, and those languages which we have mentioned above on the other. The word is one which both peoples have applied to themselves as their distinctive title (Sansc. *ârya*, Avestan *airya*), and the most ancient forms of their respective languages, as we shall see below, are hardly more than dialects of a single tongue. Iran is a further derivative from the same word (Av. *airyana*), and is usually and properly employed in a wider sense than Persia (which fairly belongs only to the S. W. province of the Persian kingdom, containing Shiraz and the ruins of ancient Persepolis), to designate the whole territory extending from the highlands that overlook the Tigris to those that border the Indus, and to the Bolor Tagh, or from the Persian and Arabian gulfs northward to the Caucasus, the Caspian and Aral seas, and the river Jaxartes; a territory which has been mainly occupied from the earliest times by a homogeneous people, of kindred language, religion, and institutions. The Persian or Iranian group of languages is one of very high interest to the philologist and the historian, from the variety of the dialects and the long history of linguistic development which they illustrate, from the marked value of the literary and historical monuments which they contain, from the importance of their modern representative, its wide extension and refined culture, and from the prominence of the Persian race during 2,000 years of the world's history. There are several other languages beside those mentioned above which stand in a near relation to the Iranian group, and are by some authorities included in it; they are the Koordish, the Afghan or Pushtu, the Beloochee, the Ossetic in the Caucasus, and the Armenian. But their relationship to one another and to the Persian is of a much more distant character; nor would there be any propriety in treating them under the head of Persian. I. *The Achæmenian Persian, or Old Persian.* This appears to have been the language of the S. W. part of the Iranian territory, or of Persia proper, during the period of widest extent and greatest power and glory of the Persian empire, under Darius the Achæmenian, son of Hystaspes, and his successors (520 to 330 B. C.). Its only remaining monuments, beside the proper names handed down to us by the classical writers, are the inscriptions of the Achæmenian princes, written in the characters called cuneiform or arrow-headed. These inscriptions are pretty fully treated of in the article CUNEIFORM INSCRIPTIONS, and specimens with translations of the inscribed texts have there been given; so that little need here be said in addition respecting their language, and that little will find its most appropriate place in connection with what we shall say of the next language, the Avestan, which is far more completely preserved and better understood. II. *The Avestan, or Old Bactrian.* This language is ordinarily known as the Zend, but the title is so unfortunate a misnomer that its use is altogether to be discountenanced and avoided. The name Zend (of disputed etymology) properly belongs, not to the language in which the Avesta is written, but to a translation of the Avesta into Huzvaresh or Pehlevi. The appellation Old Bactrian, which is favored by some of the later German scholars, as Spiegel and Haug, is open to two objections, viz.: that it contains a theory respecting the locality of the dialect, which, though highly probable, is not actually established as true; and that it seems to imply a modern Bactrian, not known to philologists. Avestan is the simplest and most characteristic title which can be given it, denoting it as the tongue in which is composed the Avesta. This work, the sacred scriptures of the religion of Zoroaster, formerly professed by all Iran, and still held by the Parsees of India, as well as by a few scattered communities of Guebres left behind in Persia, is its sole monument. The question of its age depends upon that of the period of Zoroaster himself, and of the history of the Zoroastrian scriptures, only a small portion of which, if any part, can be as ancient as the founder of the religion; and both these questions are as yet entirely undetermined, in spite of the many attempted solutions which they have received. (See ZEND-AVESTA, and ZOROASTER.) In the character of the language, as compared with its next neighbors and nearest congeners on either hand, the Achæmenian Persian and the Vedic Sanscrit, there is nothing which should lead us to any well grounded opinion as to its absolute period. In the scale of linguistic development, in remoteness of descent from the common ancestor, it occupies nearly the same place with the Achæmenian, while both are less primitive in their structure than the sacred and classical dialects of India; but such is the inequality of the rate at which different descendants of the same original tongue, under different conditions, are found to develop themselves and become corrupted and altered, that no definite conclusion can be drawn from the comparison. We can only say that the Avestan is an ancient Iranian dialect, doubtless older, and perhaps much older, than the Christian era. As regards its locality the case is more clear; the internal evidence of the Avesta is unequivocally in favor of placing it in the N. E. portion of Iran, in Bactria, on the head waters of the Oxus, or in neighboring provinces; and other testimony points to the same conclusion. It is the ancient Persian of the north-east, as the Achæmenian is of the south-west. The knowledge of this language was brought to Europe just a century ago, by Anquetil-Duperron, who went to India on purpose to recover the Zoroastrian scriptures and the means of their comprehension. Of its grammatical structure he obtained no valuable knowledge, and his translation of the texts was extremely inaccurate; his Parsee teachers, in the decay of traditional learning among them, having been able to give him but imperfect information from the translations and comments in their hands. The possession and study of these auxiliaries themselves, and more especially the comparison of the Avestan with the so nearly related Sanscrit, have enabled modern scholars to gain a far better understanding of this ancient idiom, and of the works composed in it. The Dane Rask (about 1826) was one of the first to lead the movement; it was continued by Bopp, in his "Comparative Grammar" (Berlin, 1833-'52), and more especially by Burnouf of Paris (1829-'52), who was for many years the chief representative of Avestan philology; Olshausen, Lassen, Roth, Benfey, Brockhaus, Holtzmann, and Haug have done much in the same cause; but the chief laborers in its behalf at present are Spiegel of Erlangen and Westergaard of Copenhagen, both of whom have begun to publish complete editions of all the monuments of the language, with translations and other needed helps to their comprehension. No grammar or dictionary of the Avestan has, however, as yet been made public, and the facilities for its study are very limited.—The Avestan is written in an alphabet which, unlike most of those of the Indo-European languages, reads from right to left. It came ultimately from a Semitic source, but is proximately an expanded form of that in which the Huzvaresh is written, and of an age considerably posterior to the Christian era; it has nothing whatever to do with any of the cuneiform modes of writing. How the Avesta was recorded prior to its transcription into this character we can only conjecture. It is a complete alphabet, retaining no trace of a syllabic character, but giving a separate sign for every analyzable sound, vocal or consonantal, and even, in a few cases, different signs for sounds between which it is not easy to establish a phonetic distinction. It has 13 characters for vowels, and 33 for consonants, as follows: vowels—*a*, *â*, *i*, *î*, *u*, *û*, *e*, *ê*, *ĕ*, *o*, *ô*, a nasal *a*, and a diphthongal *ão*; consonants—guttural, *k*, *kh*, *q*, *g*, *gh*, *ng*, *ñg*; palatal, *ch*, *j*; dental, *t*, *t* (almost solely final), *th*, *d*, *dh*, *n*, *ñ*; labial, *p*, *f*, *b*, *m*; semivowels, *y* (three characters, regarded as equivalent; two initial only), *r*, *v* (two equivalent characters; one initial only), *w*; sibilants, *ç*, *s*, *sh*, *z*, *zh*; aspiration, *h*. The words are written apart from one another, with a dot or point between them, and exhibit none of that interfusion of adjacent ending and beginning which is characteristic of Sanscrit euphony. The principal distinctions of this alphabet from the Sanscrit are: the absence of the lingual series (a special Indian development) and of the semivowel *l*, the addition of the intermediate vowels *e* and *o*, and of the sonant sibilants. The system of syllabic combinations of vowels, of diphthongs and triphthongs, is also very expanded and intricate; more so, it has been conjectured, than the language itself fairly warranted, involving an overstraining after the designation of vowel distinctions. Among the chief phonetic peculiarities of the language are: the general aspiration of a mute before a semivowel, nasal, or sibilant, as *jaghmushi* for *jagmushi*, *fra* for *pra*, *khshathra* for *kshatra*; the epenthesis of *i* when preceded by a dental, a labial, or *r*, especially the latter, as *airya* for *arya*, *paiti* for *pati*; also of *u* when preceded by *r*, as *aurvat* for *arvat*; and the conversion, as in Greek, of a primitive *s* into *h*, as *hapta* for *sapta*, Greek ἑπτα, Lat. *septem*; *haurva* for *sarva*, Greek ὁλος, Lat. *salvus*. The alphabet of the Achæmenian Persian differs from this less in phonetic character than in its scanty and imperfect provision for the representation of sounds; its vowel system, especially, is written with Semitic niggardliness; it has a partially syllabic character, possessing in certain cases different signs for a consonant according as it is followed by *a*, *i*, or *u*. It lacks all the sonant aspirates of the Avestan, and agrees with it in being destitute of an *l*. It has a special weakness in tolerating no final *t* or *n*, which has caused it the loss of many characteristic inflections. In general, it agrees in phonetic character with the Avestan where the latter differs from the Sanscrit. The grammatical forms of both the ancient Iranian dialects correspond very closely with those of the Sanscrit. It is only by the help of the latter language that a clear understanding of the Avestan grammar, and through it of the Achæmenian, could possibly have been attained. The scantiness of the materials, and the corruptions of the recorded texts, would have frustrated any attempt to construct the etymological part of the ancient Persian grammar from a study of the Persian monuments alone. An acquaintance with the Sanscrit is the first and indispensable requisite for one who would approach the investigation of the oldest Iranian dialects. In order to illustrate the close connection of the three idioms, and to show the prominent part which the Sanscrit has played in the interpretation of the other two, we give below a brief sentence from the Avesta (the *Abân Yesht*), with the corresponding Sanscrit below, and also the Achæmenian forms, so far as they are found to occur. Of course, the parallelism is not by any means everywhere so close; we have purposely selected a passage in which every word admitted of comparison; yet, if a favorable, it is also a truthful and telling exhibition of the exceedingly near accordance, both in grammar and in vocabulary, of the most ancient representatives of the Iranian and Indian branches of the Aryan form of speech:

Av. *daedi mê vanguhi çevisti . . . yatha azem upemem*
Sans. dehî me vasvî çavishthe yathâ aham uparam
Ach. *mîy yathâ adam*

Av. *khshathrem bavâni viçpanãm daqyunãm daêvanãm*
Sans. kshatram bhavâni viçvânâm dasyûnâm devânâm
Ach. *khshatram [bavâniy] visanâm dahyunâm*

Av. *mashyanam ca yâthwam. .*
Sans. martyânâm ca yâtûnâm.
Ach. *martiyanâm câ*

"Grant me, O excellent, most mighty one! that I may attain the chief authority over all countries, devs, mortals, and jotuns."

In the Avestan nouns, substantive and adjective, we find the 3 numbers of the Sanscrit, and its 8 cases (instrumental and locative, beside the 6 of the Latin); but in the texts the cases are not a little confounded together as regards their usage. The dual number, and some of the cases, are not to be traced in the Achæmenian dialect, probably owing to the scantiness of its monuments. The genders are 3, as in all the other early languages of the family. The whole apparatus of derivative suffixes and of forms of declension is nearly the same in both the Persian dialects as in the Indian, allowing for phonetic transmutations and some anomalies and irregularities. The same may be said, upon the whole, of the pronouns and numerals. The verbal roots are uniformly monosyllabic; but those of secondary or derived formation are notably more numerous than in Sanscrit. We find again, also, the 2 voices, active and middle, the 3 numbers, and the 3 persons of the Indian language. The tenses are 5: present, imperfect, aorist, perfect, and future. The first 2 exhibit special modifications of the root corresponding with the conjugational characteristics of the Sanscrit, but these modifications are more apt here than there to extend themselves irregularly to the other tenses also. The future is almost lost from use, and its place is supplied by the present subjunctive. The perfect and future have only an indicative mood; the other tenses possess, in more or less completeness, an optative, a subjunctive, and an imperative. Occasional instances of periphrastically formed tenses occur. Of derivative forms of the verb, we meet with passives, causatives, desideratives, and intensives, as also denominatives.

These explanations apply especially to the Avestan; the scantiness of the Achæmenian monuments is the cause that of the verbal structure their language exhibits only fragments. Yet what we have said of the eastern is doubtless true in all main particulars of the western dialect; the records make known no discordances between the two of sufficient account to be noticed here. A portion of the Avesta, the so called *Gâthâs*, or metrical ascriptions of praise, somewhat akin to the hymns of the Indian Veda, is composed in a dialect differing slightly from that of the rest of the work, and apparently of greater antiquity. So likewise some grammatical differences have been pointed out between the inscriptions of the earlier and those of the later Achæmenian princes.—The two dialects of which we have thus far treated form a sub-group, that of the ancient Iranian dialects; the remaining three also stand in a special relation to one another, as the modern Persian idioms. III. *The Huzvaresh.* This language is also called by the name of Pehlevi, which is to be discarded, as a term of doubtful etymology and meaning, and as variously and somewhat indefinitely applied by the Persians. It is represented by a complete version of the Avesta (to which belongs the name Zend), and by a few independent texts in addition, but all constituting a part of the Zoroastrian scriptures; chief among these additional texts is the *Bundehesh*, a cosmogonico-philosophical work. Some rather scanty and as yet but imperfectly deciphered inscriptions and legends on coins, memorials of the Sassanian kings of Persia, are also regarded as representing the same dialect, or a slightly different form of the same. Its fundamental character is that of a Persian idiom, occupying very nearly the same stage of development with the Parsee and the modern Persian, but especially and widely differing from them in admitting an almost unlimited intermixture of Semitic (Aramaic) words; these, however, like the Arabic introduced into the modern Persian, are fully subordinated to the Iranian element of the language, being Persianized in inflection and construction. It is as if, for Persian terms, of every part of speech, not excepting pronouns and particles, it were permitted to substitute at will synonymous Aramaic words. The aspect of the idiom is not so much that of an organic combination of two diverse tongues to produce a new language, like the English, as of an artificial or mechanical mixture, like some styles of the modern Persian. Such a mixture must apparently have been rather a conventional mode of composition than a true popular dialect, and it can have arisen only on the borders of the Semitic and Iranian territory, where the population of the two races was thoroughly intermingled, and each was familiar with the speech of the other. It is accordingly located by Spiegel, whose labors upon it are the chief medium by which it is known to the world (see especially his *Grammatik der Huzvaresch-Sprache*, Vienna, 1856), in the border lands along the Tigris, and is referred to the 5th century after Christ, and later. It has a peculiar alphabet, and one of extreme difficulty, owing especially to the defective distinction of its signs; thus, *v*, *o*, and *n* are written with precisely the same character; also *a* and *kh*; also *i*, *y*, *g*, *j*, and *d*; these last, however, being in some MSS. distinguished from one another by diacritical points. There are also numerous compound letters, digraphs and trigraphs, of a not less ambiguous and perplexing character. This alphabet, and the necessarily resulting uncertainty of reading of almost every word written with it, is the most formidable difficulty in the way of a comprehension of the language. It is of Semitic origin, reads from right to left, and, so far as it goes, is mainly coincident with the Avestan alphabet; which, as already noticed, is looked upon as an expanded and completed form of it, or of its proximate original. As both the Huzvaresh and the Parsee closely accord with the modern Persian, being but slightly more antique dialects of it, and as a main part of their linguistic value lies in the light which they cast upon the history of the Persian, we shall, in order to greater clearness as well as to economy of space, speak of their phonetic and grammatical form in connection with our description of that of the modern dialect. IV. *The Parsee.* The name Parsee is applied, for convenience' sake, to a pure Iranian dialect, slightly more modern in its forms than the Huzvaresh, and approximating nearly to the Persian, from which it is distinguished by its retention of a few ancient forms of inflection, and many ancient words and phrases, which the later idiom has lost. The scanty literature which represents it belongs to the body of Zoroastrian scripture, and is believed to be composed wholly of translations from Huzvaresh originals. Its almost entire freedom from Semitic elements shows it to belong rather to some central or eastern portion of the Iranian territory than to the west; its period is supposed to be that of the later Sassanian monarchs and the early times of Moslem supremacy. It is written sometimes in the character of the Avesta, and sometimes in the Arabic alphabet, as adopted by the modern Persian. The chief source of our knowledge of it is Spiegel's grammar (*Parsi-Grammatik nebst Sprachproben*, Leipsic, 1851). V. *The Modern Persian.* By this we mean the language which has been during 900 years past the cultivated language of Persia. In distinction from the popular dialects of the country, it is called *Deri*, "court language." How far it differs from them we are not sufficiently informed, nor have we satisfactory knowledge respecting the condition of the idioms of the various parts of the country. According to native authorities, each considerable province has a dialect of its own, and that which is spoken in and about Shiraz and Ispahan approximates most nearly to the cultivated tongue. Persian is still spoken, not only throughout the present kingdom of Persia, but all over the Iranian territory, and even beyond its borders; but its prevalence is different in different regions. About the Caspian it is in great measure crowded out by the dialects of the almost exclusively Turkish population. Throughout a great part of Khorassan the Persian is the language of the cities, while the nomadic tribes who occupy the surrounding wastes are of Tartar descent and idiom. In other parts this relation is in a manner reversed; thus, in Afghanistan and Beloochistan the ruling race is of another, though ultimately kindred lineage, while the mass of the agricultural population is made up of Persian-speaking Tajiks. Nearly the same is the case in the southern portions of Toorkistan or Independent Tartary, an ancient seat, as we have seen above, of Iranian religion and civilization; and the Iranian population even extends beyond the Bolor Tagh into some of the provinces of Chinese Tartary. Conquests, commerce, and culture have combined to carry the Persian language beyond its ancient limits; the subjugation of India by Persian monarchs introduced it as the court language of Delhi, and made Hindostan long a centre of Persian literary culture; it is but recently that Persian has ceased to be the recognized official language of British India. The Turks have carried it, in a certain way, as far in the opposite direction; the cultivated Osmanli is full of Persian words and phrases, and its literature is in great part founded upon Persian models.—The appearance of the modern Persian language, and the rise of its literature, are contemporaneous with the disintegration of the caliphate of Bagdad, and the resurrection of Persian nationality under native and virtually independent sovereigns in the 10th century. During the 3 centuries that Persia had lain under the heel of its Mohammedan conquerors, its national independence destroyed, its religion and social institutions swept away, it had exercised in virtue of its superior culture a powerful influence upon its oppressors, and its scholars had borne a prominent part in starting into life the Moslem literature, philosophy, and science; but not until after the lapse of that interval did there take place a revivification of elements distinctly Persian. With the latter part of the 10th century, then, begins the career of the modern Persian, of which we shall now proceed to give a concise description. The Persian is hardly to be considered as the direct lineal descendant of either of the two ancient dialects, the Achæmenian or the Avestan, but it is more nearly related to the former than to the latter, as is shown by such evidences as the infinitive ending *ten*, Ach. *tanaiy*, Av. *teê*; *dest*, hand, Ach. *dasta*, Av. *zasta*, &c. As already remarked, it is closely connected with the Parsee, and with the Iranian portion of the Huzvaresh, being but a slightly modernized form of the same tongue. As an analytical language, exhibiting an almost complete breaking down and abandonment of the ancient system of forms and inflections, and the substitution of independent form-words and connectives, it stands quite upon a level with the English; its grammar, in striking contrast with the complexity of that of the two ancient dialects, is of the baldest simplicity. It is always written with the Arabic alphabet, to which, however, it has added 4 signs, to express the sounds *p*, *ch*, *zh*, and *g*; on the other hand, 8 or 9 of the Arabic characters are useless to it, occurring, save in very rare cases, only in Arabic words, and being pronounced, like other letters in the alphabet, without the distinctive Arabic utterance. The spoken alphabet is nearly as follows: vowels, *a*, *e*, *i*, *o*, *u* (as to the vowel pronunciation, even of the cultivated dialect, there appears to exist much diversity in different regions; the vowels are written, of course, in the very imperfect Semitic fashion, sharing among them only 3 characters, and generally omitted when short); consonants—guttural, *k*, *kh*, *q*, *g*, *gh*; palatal, *ch*, *j*; dental, *t*, *d*, *n*; labial, *p*, *f*, *b*, *m*; semivowels, *y*, *r*, *l*, *v*; sibilants, *s*, *sh*, *z*, *zh*; aspiration, *h*. The Parsee alphabet is almost precisely the same with this, nor does that of the Huzvaresh present any difference worthy of notice. All show a near relationship with the systems of sounds of the ancient dialects, differing from them chiefly by the loss of certain aspirates (the dental), and by the possession of an *l*.—In treating of declension, we have first to note the fact that the Persian, like the English, has lost all suffixes and terminations distinguishing gender, and that it accordingly agrees with our language in possessing no artificial or grammatical gender. It is yet poorer than the English in lacking the distinction of gender in the pronoun; it cannot even say "he, she, it;" where a distinction has to be made between masculine and feminine, it employs separate words meaning male and female. The same is the case in the Parsee and Huzvaresh. There are two endings for the plural, *ân* and *hâ*, the former a relic of the ancient genitive plural (*asp-ân*, horses, Av. *açpanâm*, of horses), the latter of the dative and ablative (*asp-hâ*, Av. *açpaêibyaç*, to or from horses; a few Parsee words have the fuller form *hyâ*); *ân* is now regularly restricted to animate objects, but in the Parsee is applied to both animate and inanimate, and in the Huzvaresh is the only plural termination. The syllable *râ* is used as a sign of the accusative (*asp-râ*); it is originally an independent word, meaning way, and in the two elder dialects is not an accusative termination, but adds to the noun the idea, "by way of, by reason of;" if an adjective follows the noun, the syllable is appended to it instead of to the noun (*asp-i-bad-râ*, the bad horse). Between a genitive and the noun which governs it is inserted the so called *izâfet*, or the vowel *i*, as *asp-i-merd*, the horse of the man; the same is also interposed between the substantive and the adjective which agrees with it, as *asp-i-murdeh*, dead horse. The beginning of this usage is to be traced even in the Avestan; the inserted syllable is a relic of the relative pronoun *ya*, which has come to assume the office of indicating alone a relation originally expressed also by the termination of the following word. Thus, the former expression would have been in Avestan *aspo yo mashyâhê*, the horse which (is that) of the man; the latter, *aspo yo mereto*, the horse which (is) dead. In the Parsee and Huzvaresh, this *i* also stands in other connections, as an ordinary relative pronoun. Some philologists, without sufficient reason, have chosen to see in the use of the *izâfet* an imitation of the construct state of the Semitic noun, and as a proof of Semitic influence. Singularity or individuality is indicated by an appended *î*, as *asp-î*, a single horse; this *î* is a remnant of the older *aêva*, one, and by the two next earlier idioms is used also as an independent numeral. The language possesses neither definite nor indefinite article. The suffixes of comparison of adjectives are *ter* for the comparative, *terîn* for the superlative; the latter is a peculiar Persian development; the two older dialects have *tum*, corresponding to Av. *tema* (Sans. *tama*, Lat. *timus*). The Persian and Parsee pronouns are pure Iranian, modern representatives throughout of those presented by the ancient dialects; the Huzvaresh employs as often, or yet oftener, Semitic forms. The three later idioms have a complete set of suffix pronouns, which are, for the three persons, singular *em*, *et*, *esh*, plural *emân*, *etân*, *eshân*; in the Persian they are attached especially to nouns and verbs, to express the genitive, dative, or accusative relation, as *asp-em*, my horse, *guftem-esh*, I spoke to him; in the older idioms they are appended only to conjunctions, prepositions, and other pronouns as *az-et*, from thee. They are a perfectly organic growth of the Iranian language, and are not to be attributed, any more than the *izâfet*, to Semitic influence.—The Persian verb has preserved hardly more of its original structure than the noun. It has indeed a complete and invariable set of personal endings, viz.: *em*, *î*, *ed*, *îm*, *îd*, *end*; but its tenses are mostly formed periphrastically. The infinitive ends in *ten* or *den* (Parsee usually, Huzvaresh always, *tan*), which corresponds to the Achæmenian *tanaiy*; the past participle in *teh* or *deh* (Ach., Av., and Sans. *ta*). From this participle is formed a preterite, by striking off the *eh*, and appending the forms of the present tense of the auxiliary to be, which, except in the third person, *est*, agree precisely with the personal ending just given; thus, from *kerden*, to do, part. *kerdeh*, pret. *kerdem*. This becomes an imperfect by prefixing *mî* or *hemî*, which in Parsee and Huzvaresh is an independent word, meaning always, continually. From the unabbreviated participle, with the present and preterite of the same auxiliary, come a perfect and pluperfect, *kerdeh em* and *kerdeh bûdem*. A future is formed by prefixing to the apocopated infinitive the present of the verb to will, to wish, *khâhem kerd*. The imperative of this verb is *kun*; the irregular verbs, which are numerous, and as usual the oldest and the most used of all, present always a discordance between the forms of the root as they appear in the infinitive and imperative respectively, and in this consists their irregularity; these two forms being given, the rest of the verb follows as a matter of course. Sometimes the one, sometimes the other, shows the root in a purer and more original form; in *kun* we have it as affected by the conjugational peculiarity of the ancient present and imperfect; compare Ach. *a-kun-avam* (imp.), Av. *keren-aomi*, Sans. *kru-omi*. By adding to the imperative the personal endings, we obtain the only original and simple tense of the Persian verb, corresponding to the ancient present and imperfect, and having the value of both present and aorist; it is made distinctively the former by prefixing *mî* or *hemî*, already spoken of. Of the ancient subjunctive we have a single trace, in an optative 3d person singular: *kunâd*, may he do! The passive is formed by the auxiliary *shuden*, meaning originally to go.—The facility of composition in the Persian is very great; epithets formed of a noun and a verbal, of an adjective and a noun, and of two nouns, are of the most frequent occurrence. A very characteristic feature of Persian style, too, is the formation of a compound or derivative verb by combining an adjective or noun with some one of a large class of half auxiliaries, of which the most frequent are to do, to make, to bring, to have, to show, to come, to become, to take, and to find. It is partly by the favoring influence of such processes of composition that the Persian has become in later times so impregnated with Arabic. The earliest Persian writers, as Firdusi and the translator of Tabary's Arabic history, wrote in a nearly pure Iranian dialect, with no greater infusion of Arabic words than was natural and unavoidable, considering the position and influence in Iran of the Arab religion and culture. But a less legitimate mixture soon began to prevail; every highly cultivated Persian was as familiar with Arabic as with his own mother tongue, and a depraved and servile taste introduced the practice of drawing upon the Arabic lexicon not only to fill out felt deficiencies of the Persian vocabulary, but, from affectation and pedantry, to such an extent as to half convert the language into Arabic. Often the merest necessary cement of a sentence or paragraph is Persian, all the materials of which it is composed being Arabic; and occasionally such a monstrosity is met with as a sentence or phrase which is pure Arabic, even to its construction. Hence, no one can now make himself a thorough Persian scholar, or gain a familiarity with the Persian literature, who has not first mastered the Arabic. In the present low condition of Persian nationality, any reaction against this abuse is hardly to be looked for; it is the rankest injustice on the part of the Persian toward his mother tongue, which is one of the most copious and flexible, the most sonorous and musical, the most cultivable, highly cultivated, and elegant of modern languages. It may not be useless to add here that the theory of a specially intimate connection between the Persian and the Teutonic (German) languages, and so between the races also who speak them (a theory at one time much in vogue, and counting some famous names among its supporters), is only the dream of a crude and childish philology, and is entirely destitute of real foundation.—LITERATURE. The scanty literatures of the three earlier Persian dialects, the Avestan, the Huzvaresh, and the Parsee, being comprised within the limits of a single work, or connected body of writings, which together make up the sacred scriptures of the modern Parsees, will be best considered together in the article ZENDAVESTA. We shall accordingly speak here only of the modern Persian literature. The date and mode of the origin of this literature have already been briefly stated above, in speaking of the language in which it is composed. A national feeling, and an active literary spirit, must have been already for some time stirring among the masses of the Persian population, to lead to so immediate and hearty a recognition of the claims of song on the part of all the upstart dynasties of eastern Iran, which succeeded one another so rapidly during the 9th and 10th centuries. Each court had its bards, whose panegyrics, and the admiration of whose powers, shed lustre upon the throne. Royal patronage has borne an important part in the whole history of Persian literature; one of its chief branches is panegyric, and few of its great names were not attached to the personal suite, or recipients of the special bounty, of some monarch. Even the wild Tartar tribes which burst one after another into Iran, and subjugated it to their sway, were at once softened and charmed by the strains of Persian song, and their barbarian dynasties became, without exception, its lovers and protectors. Had not the feeling been genuine, the genius strong, the national appreciation universal and hearty, such patronage must soon have corrupted the rising literature, converting it into mere servile adulation. Of servility and adulation there was indeed enough; but along with it a true, healthy, growing, and productive literary life, during more than 5 centuries. We can give here, of course, but an outline sketch of its development, and can mention only the most prominent and highly considered of the hundreds of authors of note, whose works or whose reputation have come down to later times. Although names and fragments of poetry of an earlier date have escaped oblivion, it is under Mahmoud of Ghuznee, the first Moslem conqueror of India, and on the extreme eastern verge of Iran, that the national literature was fairly launched on its new career. Under this prince, and at his bidding, Firdusi sang his immortal epic, the *Shah Nameh*. This earliest of the Persian poets remains unexcelled in genius and dignity by any of his successors. His work summed up the whole mass of native traditions respecting the national history; it is a true national epic, a final relation, accepted by a whole people, of its own popular legends. No other Persian poem enjoys the wide repute of this; none other has the same high interest to us of the West. Of epic-romantic poets, the most famous is Nizami, who died 80 years after Firdusi, in 1200. His "Quinquiad," or collection of his 5 best romances, became the model of many a like collection in later times. From among the innumerable crowd of those who have distinguished themselves especially by their panegyrical writings, we need mention but two: Enveri, the acknowledged prince of panegyrists, who died at Balkh in 1152, and Khakani, who lived a generation later. Both are remarkable for learning, as well as for fertility of fancy and elegance of style. An important branch of Persian literature, and one which began to develop itself very early, is that which represents the doctrines of the Soofees, or religious mystics. Doubtless we are to recognize a certain resistance on the part of the Persians to the slavery into which they were forced to Arab faith and doctrine, in their general adoption, on the one hand, of the unorthodox and detested tenets of the Sheeahs, who accept the Koran and Mohammed, but deny the right of the first three caliphs; and, on the other hand, in the prevalence of mysticism among them. Persia, if not the home of Soofeeism, as has been both maintained and denied, is at least the ground where it has most fully developed itself, and held longest and most exclusive sway. The oldest Soofee poet of great celebrity is Zenayi, who died in 1180; his works were superseded by the yet more highly esteemed productions of Ferid-ed-din Attar, who, born in 1216, lived more than 100 years, and was slain at last in the Mongol storm and sack of the city where he dwelt. His works are unintelligible in their interior meaning without special commentaries. Among them, the most esteemed are the "Book of Counsel" (*Pend Nameh*), "Language of the Birds" (*Mantik-uttair*), and "Essences of Substance" (*Jevahir Nameh*); the two former have been published and translated in Europe. Even Attar was excelled, however, by his younger contemporary Jelal-ed-din Rumi (died 1262), the founder of the most widely extended order of Moslem monks, the Mevlevi, and author of the *Mesnevi*, the chief oracle of Soofeeism, and, next to the *Shah Nameh*, the most generally known and highly esteemed (in the Orient) of all the productions of oriental literature; its profundity, its sublimity, and its inspired wisdom are regarded as unapproached and unapproachable. It could not fairly be expected, however, that the less imaginative and more practical occidental taste should appreciate and delight in these bursts of the transcendental enthusiasm of the Orient. A poet more to our mind, and who has done more than any other for the fame of Persian poetry in the West, is Saadi. He belongs to the same period with the authors last named, having died in 1291, at the advanced age of 102 years. He is said to have spent the second 30 years of his life in travelling, and the third in meditating upon and digesting his acquisitions and experiences, and only the last 12 years in the actual composition of his immortal works. If sceptical as to the literal truth of this systematic division of his life, we need not question that he travelled and saw much, and wrote his most esteemed productions at an advanced age. We know that he lay for some time in Christian captivity, taken prisoner in battle with the crusaders. In both these circumstances has been sought an explanation of the cooler fancy, the purer taste, the more practical morality, which distinguished Saadi among oriental authors. He is most eminent as a moral and didactic poet; his two best works, the "Fruit Garden" (*Bostan*) and "Flower Garden" (*Gulistan*), are collections of brief tales and apologues, interspersed with aphorisms and lessons of morality, in prose and verse; both have been translated into nearly all the languages of Europe. By his countrymen Saadi is equally esteemed as a lyric poet. But the greatest of Persian lyrists is Hafiz, of Shiraz, who lived a century later (he died in 1391); in him Persian poetry is regarded as having attained its very highest flight. Though a dervish, deriving his name (Hafiz, retainer) from his knowing by heart the whole Koran, and though living always in contempt of wealth and splendor, he was a thorough free-thinker and indifferentist in matters of religion, and his inspiration is solely that of the most enthusiastic and intoxicated sensual enjoyment; the unvarying themes of his song are love and wine, the rose and the nightingale. A mystical explanation has been given to the outbursts of his passion, and the same poems which are sung as erotic and drinking odes by the young debauchee, are pored over by the aged devotee as containing the essence of holy ecstasy; but the interpretation is forced and false, and mainly a device to save the pride of Persian literature from condemnation as an infidel and sensualist. Persian poetry has but one other great name to boast after Hafiz; it is that of Jami, who lived a century later, dying in 1492, at an advanced age. He is a poet of the most varied genius, and, though not accounted as the very first in any department, he is exceeded only by the very first in each; thus, in panegyric he is esteemed as second only to Enveri, in romance to Nizami, in mystic poetry to Jelal-ed-din, in moral and didactic to Saadi, in lyric to Hafiz; these 5, with Firdusi and himself, being admired as the 7 most brilliant stars in the firmament of Persian poetry. The fame of Jami stands highest, perhaps, as a romantic poet, though prose works of high merit have also come from his pen, including a history of the Soofees, and a collection of letters as models of epistolary style, a branch of elegant literature much cultivated by the Persians in later times, and in which Jami is unexcelled. With the 15th century closes the proper history of Persian poetry; since that time, although much increased in extent, it has grown little in value.—We have hitherto spoken only of the poetry of Persia, because that is by far the most important and valuable department of the national literature. Next to it in consequence is the department of history. For the older traditional history of Persia itself, Firdusi has continued the chief and almost sole authority; later writers have added little to what is recorded in the *Shah Nameh*. But a host of later historians, beginning from rather a recent period, about the middle of the 13th century, have treated of the later Persian history, especially of that of Genghis Khan and his descendants and successors, and of the remarkable overturnings of Asiatic power of which Iran has been a principal scene; and their works are important sources of the world's knowledge respecting the events of the period. Among the chief names here are Reshid-ed-din (born 1247), Wassaf (of the same epoch), whose elaborate and excessively ornate style makes him one of the most difficult of Persian authors, and Sheref-ed-din, the historian of Tamerlane. Of later authors, Mirkhond (died 1497), a writer of universal history, and his son Khondemir, are most distinguished. An important branch of Persian history, too, has India for its native place and its theme. In entertaining or amusing literature, such as fables, tales, anecdotes, legendary and supernatural stories, and the like, Persia is very rich, and it is supposed to be the source whence much of the European literature of this class, dating from the middle ages, was derived. In Moslem theology and jurisprudence, as was to be expected, the Persians are chiefly dependent upon Arabic authorities, and have produced no literature requiring mention here. In philosophy and the exact sciences nearly the same is the case, yet rather in appearance than in reality, and because the Persian savants have chosen to write in the Arabic language rather than in their own; a large proportion of the most highly considered scientific works in the Arabic literature are by Persian authors.—Helps for the study of Persian abound in England. The best grammars are those of Sir William Jones, by Wilkins (1809), Lumsden (2 vols. fol., Calcutta, 1810), Prof. Lee (1828), and Duncan Forbes (1844). The most remarkable monument of Persian lexicography is *Haft Kulzum*, "The Seven Seas," a dictionary in 7 vols. fol., by the king of Oude (printed at the royal press, Lucknow, 1822); and the most useful, Richardson's "Persian, Arabic, and English Dictionary," by Wilkins and Johnson (4to., 1829).

PERSIAN GULF, an arm of the Indian ocean which lies between Persia and Arabia, extending from lat. 24° to 30° N., and from long. 48° to 57° E.; extreme length 600 m., breadth from 40 to 200 m.; area estimated at 80,000 sq. m. Its entrance from the Indian ocean is through the Arabian sea, the gulf of Oman, and the strait of Ormuz, the last of which is about 35 m. wide. The shores are much indented along both coasts; but the only harbors of importance are Bushire on the Persian side, and Bassorah near the N. end, on the westernmost mouth of the Shat-el-Arab, the river formed by the junction of the Tigris and Euphrates. The coasts of the gulf are low, except near the entrance, where the mountains on both sides rise to a considerable height and come close to the sea. On the S. or Arabian side there are numerous shoals and reefs, which render the coast exceedingly difficult of approach in large vessels. There are several islands in the neighborhood of the Arabian shore and the strait of Ormuz, the most important of which are Kishen, Ormuz, and Aval or Bahrein islands. The only river of any considerable size that falls into the gulf is the Shat-el-Arab. At the straits of Ormuz the tide rises 12 feet, and about the N. end of the gulf 6 feet. There are pearl fisheries in the neighborhood of the W. and S. shores, the value of which is estimated at $1,500,000 per annum.—The whole of the shores of the Persian gulf are inhabited almost exclusively by Arabs. For many years the gulf was infested by pirates, who when pursued found safety among the shoals and islands on the coast of Arabia. In 1809, and again in 1819, the British sent expeditions against them from Bombay, which, in conjunction with the imam of Muscat's forces, completely destroyed their vessels, and they have been since held in subjection by the constant presence of cruisers. The Persian gulf is the ancient sea of Babylon, and the earliest profane record which we have of its navigation is that of the voyage of Nearchus in 325 B. C.

PERSIGNY, Jean Gilbert Victor, count de, a French statesman, born at St. Martin d'Estréaux, department of the Loire, Jan. 11, 1808. His family being in reduced circumstances, he enlisted in the army as a private when 17 years old, was afterward admitted to the military school of Saumur, and rejoined the army as a non-commissioned officer of hussars. After the revolution of 1830, being suspected of entertaining seditious designs, he was dismissed. He became a contributor to the newspaper *Le temps*, and a faithful adherent of the Saint Simonian doctrines, so much so that in 1832 he followed Father Enfantin to Menil-Montant. He visited La Vendée at the time when the duchess of Berry was concealed there; returned to Paris to assist in the making up of a legitimist correspondence, to be furnished to the provincial newspapers; and now assumed the title of viscount de Persigny. Convinced that there was no hope of a restoration of the Bourbons, he became a Bonapartist in 1834. A paper of his, *L'Occident Français*, attracted the attention of the Bonaparte family, and he visited Arenenberg, with a letter of introduction to Louis Napoleon, who was then styled Prince Louis. A close intimacy between the two young men was the consequence of this visit; and Persigny at once set to work to organize the Bonapartist party. The result of his exertions was the attempt upon Strasbourg in 1836. More fortunate than his companions, he escaped and repaired to England, where he published an apologetic account of the expedition, *Relation de l'entreprise du prince Napoléon Louis* (London, 1837), which was reprinted in New York. In July, 1840, he participated in the landing at Boulogne, and was taken prisoner, arraigned before the court of peers, and sentenced to 20 years' imprisonment. From Doullens, where he was first incarcerated, he was allowed to remove on account of ill health to Versailles, where he enjoyed comparative liberty. Here he wrote an essay entitled *L'utilité des pyramides d'Égypte* (1844), which he presented to the academy of sciences, and in which he asserts that those gigantic constructions were merely built to protect the valley of the Nile against the encroachments of the sand of the desert. On the revolution of 1848 he returned to active life, and exerted himself to secure the election of Louis Napoleon to the presidency. On the latter's accession to power Persigny was chosen his aide-de-camp, and appointed to a high rank in the staff of the national guard. In 1849, being elected by the departments of the Nord and Loire to the legislative assembly, he sat for the latter, and proved an uncompromising supporter of the presidential policy. He was meanwhile sent on a temporary mission to Berlin. On the *coup d'état* of Dec. 2, 1851, in the preparation of which he was concerned, he appeared at the head of the 42d regiment of the line and took possession of the hall of the assembly, and was appointed a member of the consultative committee. As a reward for his services, he received, May 27, 1852, the hand of Eglé Napoléone Albine, the granddaughter of Marshal Ney, the title of count, and a gratuity of 500,000 francs. In Jan. 1852, he was appointed minister of the interior in place of M. de Morny, who had refused to sign the decree confiscating the Orleans property; he continued to hold this office until April, 1854, when he resigned on account of ill health. The following year he was appointed ambassador to England; he resigned in April, 1858, was reappointed in May, 1859, and still holds the office. In 1857 he was promoted to the rank of grand cross of the legion of honor, of which he had been created a chevalier in 1849.

PERSIMMON. See Date Plum.

PERSIUS FLACCUS, Aulus, a Roman satirical poet, born in Volaterræ, Etruria, Dec. 4, A. D. 34, died Nov. 24, 62. He belonged to the equestrian order, and after receiving the rudiments of a good education from his mother, for whom he always showed the strongest affection, went to Rome and studied with Lucan under the stoic philosopher Annæus Cornutus. Little more is known of his life, but he was distinguished for his blameless morals and amiable character. His extant works consist of 6 satires, which comprise in all no more than 650 hexameters, and there is no proof that he ever wrote more. His style is obscure, and abounds in colloquialisms, far-fetched metaphors, and abrupt transitions. Quintilian, Martial, and some of the early Christian writers speak in high terms of his merits, while others consider him not worth reading. The best editions of Persius are those of Jahn (Leipsic, 1843) and Heinrich (Leipsic, 1844). English translations have been made by Holyday, Dryden, Brewster, Sir William Drummond, and Gifford. The last has been published, together with a literal prose version by the Rev. L. Evans, in Bohn's "Classical Library."

PERSON, a N. co. of N. C., bordering on Va., and drained by branches of the Dan and the head waters of the Neuse river; area about 400 sq. m.; pop. in 1860, 11,221, of whom 6,195 were slaves. It has a diversified surface and a generally fertile soil. The productions in 1850 were 289,072 bushels of Indian corn, 49,802 of wheat, 1,562,119 lbs. of tobacco, and 18 bales of cotton. There were 6 grist mills, 4 tobacco manufactories, 2 tanneries, 18 churches, and 809 pupils attending public schools. Capital, Roxborough.

PERSONAL EQUATION, a term applied by astronomers to an error to which every observer is liable in marking the precise instant of a star's transit. Some observers anticipate the instant of contact, and some are behindhand in recording it; and curiously enough, the error is constant in kind; that is to say, one observer will give the time too early and another too late, not occasionally, but always. It is constant in quantity also, and accordingly the personal error of an observer is commonly given in decimals, and must be allowed for in all delicate calculations. It is not a fault of inexperience, but an imperfection common to the greatest observers, and seems to be positive or negative according as the temperament inclines to the sanguine or to the phlegmatic. It is by no means an insignificant source of error. In 1823 Bessel and Struve made a difference of an entire second in their respective records of an observation.

PERSPECTIVE, the art of representing on a plane surface objects as they appear to the eye from any determinate point of view. All the points of the surface of a body are visible by means of luminous rays proceeding from these points to the eye. If we suppose a vertical plane to be interposed between the object and the eye, and the intersection of these rays to be properly designated upon the plane, there would be marked upon it an image of the object, or perspective of it as seen by the eye. As we look out of a window, the glass may be considered the intersecting plane; and if we could draw or paint upon the glass the objects visible through it, the painting would be a true perspective. But only one eye must be used, as each eye, having its own view, sees the objects in a different place on the plane of the glass. This may be readily understood by closing the eyes alternately, and observing near objects, or in the contemplation of the views in a stereoscope, which appear as one. A different view opens to the eye at every change of position; the eye must therefore be kept still, which may be effected by a fixed sight or aperture through which the eye is directed during the sketching. As glass is inconvenient both to draw on and to preserve, it may afford an intelligible plane, but not a practical one for the purposes of sketching; this may be obtained through the means of finely perforated paper in which several apertures are contained within an area equal to the pupil of the eye, so that every part of each object is seen by some part of the eye, while other parts have a full view of the paper on which the objects are to be drawn; the view is thus transmitted through the paper with sufficient distinctness to enable the draughtsman to trace an outline on the inner surface of the paper. The paper must be placed vertically. The paper or plane on which the drawing is made is called the plane of the picture, the position of the eye the point of sight, and an imaginary horizontal line at the level of the eye the horizon. Toward some points in this line all straight lines not parallel with the plane of the picture converge; these points are called vanishing points. A picture, to be seen in true perspective, should be observed at the same distance from the plane of the picture and the same position of the eye under which it was drawn; but custom enables us to disregard these requirements, and appreciate a true picture even when looking with both eyes and from varied points. The perspective of objects being obtained by the intersection of the rays which emanate from them to the eye, with a vertical plane between the eye and the objects, the science may be resolved geometrically into the problem of constructing the section by a plane surface of a cone of rays of which the summit and base are given, the eye being the summit, the whole visible extent of the object or objects to be represented being the base, and the intersecting surface the plane of the picture. The resolution of this problem is the science of linear perspective. The faces of objects parallel with the plane of the picture are said to be in parallel perspective; faces oblique to this plane, in angular or oblique perspective. In the contemplation of a landscape, we observe that the objects nearest us are most distinct in outline and color; as they recede from the view the forms become vague and shadowy, and the colors lose their intensity and blend together. In painting a picture, therefore, to harmonize with nature, it must not only be drawn in true perspective, but it must also be colored in reference to the proximity of the objects to the spectator. This is termed the art of aërial perspective, since the softening of effect is due to the interposition of the medium through which the objects are seen, *i. e.*, the air.—To give a sort of perspective effect to the drawing of an object and yet enable it to be measured by a scale, to make a picture and yet have it adapted for mechanical construction, a projection has been devised, called isometrical perspective. The principle of this consists in selecting for the plane of the projection one equally inclined to 3 principal axes at right angles to each other, so that all straight lines coincident or parallel to these axes are drawn on the same scale; thus the projection of a cube would be in outline a regular hexagon divided into 3 equal rhombuses representing the adjacent faces. Isometry is especially applicable to mechanical and architectural drawings, as embracing in one view, and with sufficient naturalness, planes and elevations.

PERSPIRATION, the excrementitious aqueous fluid secreted by the sudoriparous glands of the skin, and also the product of simple physical transudation mixed with it. These glands consist of long convoluted tubes in the fatty tissue beneath the skin; the minute tubes unite to form a single duct, which passes up through the skin in a spiral manner, opening on the surface of the epidermis obliquely, so that its outer layer makes a kind of valvular covering. (See Diaphoretics.) There is a constant and generally insensible separation of fluid in the form of vapor by these glands; but when it is increased beyond evaporation by exercise, heat, or disease, it forms minute drops on the skin, commonly known as perspiration and sweat. It is usually acid from the presence of acetic or lactic acid, whence the sour smell observed in many disordered states of the system; the proportions of solid matters vary from 4 to 12 in 1,000 parts, these consisting principally of a proteine compound in a state of incipient decomposition (and in diseased conditions urea), with chlorides of potassium and sodium, and other saline compounds. In the perspiration from external heat, or from other causes of special determination of the blood to the skin, the product of transudation is increased, but the amount of solid matter is not augmented; the profuse perspiration after exercise in warm weather is not the cause of the fatigue experienced, but rather the diminished activity of respiration from the less amount of carbonic acid exhaled from the lungs at high temperatures; the colliquative sweats of phthisis and other exhausting diseases are the consequences rather than the causes of the general debility of the system. The amount of insensible cutaneous perspiration lost in 24 hours is from 1 to 3⅛ lbs., that of the lungs being from ⅜ to 1⅜ lbs. in the same time; this varies according to the external temperature and condition of the body; a hot and dry air, causing a greater determination of blood to the skin, produces a more active transudation, which passes off as insensible vapor, but in a moist atmosphere appears as sensible perspiration or sweat; it is also influenced by the state of the system and the quantity of fluid taken into the stomach. The vicarious offices of the perspiration and urine are noticed under Kidney; these are performed not only in regard to the amount of fluid eliminated, but also to that of the products of the waste of the system. It has been estimated that at least 100 grains of nitrogenized matters are daily excreted by the skin, and whatever interferes with this process tends to disorder the functions of the kidneys. Depressing emotions, especially fear, increase the perspiration, and great nervous excitement diminishes it; the destruction of the skin by an extensive burn, and the consequent suppression of the perspiration, produces death by congestion of the lungs; a varnish applied to the skin of a frog stops the transpiration, and causes death by "cutaneous asphyxia," the blood being imperfectly arterialized and the temperature much depressed. The fluid of simple transudation by its constant evaporation keeps down the heat of the body, the process being active according to the warmth and dryness of the air; the internal heat, however, is principally regulated by the secretion of the cutaneous glands, its evaporation carrying off a large quantity of free caloric which would otherwise raise the body's temperature; simple dry heat increases the secretion and evaporation, but heat and moisture combined check evaporation. Any sudden diminution of an active perspiration by exposure to cold disturbs the circulation, and brings on a variety of diseased conditions, for the treatment of which see Diaphoretics.

PERTH, a W. co. of Canada West, drained by the sources of Thames river; area, 698 sq. m.; pop. in 1851, 15,545. It is intersected by the Toronto and Goderich railway. Capital, Stratford.

PERTH, a city of Scotland, capital of Perthshire, picturesquely situated on the river Tay, here crossed by an elegant bridge, 45 m. by railway N. by W. from Edinburgh; pop. in 1851, 22,232. It is one of the most ancient cities in the kingdom, and was once surrounded by walls. It is connected by railways with the rest of the kingdom, and has some manufactures of cotton goods, &c. In 1851 the registered tonnage of the port amounted to 68 vessels of 5,535 tons. Perth is supposed to be of Roman origin, was at one time the capital of Scotland, and has been the scene of some remarkable events in the history of that country. It was captured by Edward I. in 1298, by Montrose in 1644, and by Cromwell in 1651. It was occupied by Dundee in 1689, and by the highlanders in 1715 and 1745.

PERTHES, Christoph Friedrich, a German book publisher, born in Rudolstadt, April 21, 1772, died in Friedrichroda, near Gotha, May 18, 1843. When 12 years of age he entered the gymnasium at Rudolstadt, and in 1787 was engaged in the bookselling establishment of Böhme at Leipsic. While serving his apprenticeship he fell sick, and was obliged to remain in his room 9 weeks, during which time Frederika, the daughter of his master, read to him a translation of Muratori's "History of Italy." Some time after a new apprentice, Nessig, arrived, and Perthes and he, both discovering that they were in love with Frederika, confided the fact to each other, and agreed that the one who failed should bear his fate without complaining. In 1793 he went to Hamburg, as an assistant to Hoffmann, Nessig undertaking the task of giving a trustworthy account of the state of Frederika's affections. After remaining 3 years with Hoffmann, he entered into partnership with Nessig. Both hereupon offered themselves to the daughter of their old master, and were both refused, although she admitted that she loved both. Perthes for a time felt the disappointment keenly, so much so that he wrote: "My whole life-plan is ruined, ruined by her;" but in process of time he recovered from his despair, and subsequently going into business alone, he married the daughter of Claudius, editor of the *Wandsbecker Bote* newspaper. While an apprentice to Böhme, he had made the acquaintance of Goethe, Herder, and Schiller, and now became known to other literary men, among whom were F. H. Jacobi, the Stolbergs, Voss, and Reventlow. In 1799 he entered into partnership with Besser, and the business of the firm went on prosperously until Hamburg was incorporated into the French empire. Even then it flourished in spite of the Berlin and Milan decrees, and of the censorship of the press. But his hostility to the French, when they retired from Hamburg before the Russians in 1813, made him a marked man, and on their return he was forced to fly, and his establishment was plundered. During all of these trials he was sustained by his wife, who thanked him that his name "stood among the 10 enemies of the tyrant," and, although in extreme destitution, encouraged him to do his duty. In 1814 he returned to Hamburg, and the firm regained its old prosperity. Dissolving his connection with Besser, he went in 1822 to Gotha, where he engaged still more largely in publishing, issuing works chiefly on history and theology. Here he published the *Almanach de Gotha*, the "General History of the States of Europe," edited by Heeren and Ukert, and the works of Neander, Tholuck, Bunsen, Ullmann, and many others. He afterward gave up his business to his son Justus, by whom it is now conducted. The correspondence of Perthes was extensive and valuable, and specimens of it may be found in "The Life of F. Perthes" (3 vols. 8vo., 1848–'55), written by his son Clemens Theodor. This work after some condensation was translated into English (2 vols. 8vo., Edinburgh, 1856).

PERTHSHIRE, one of the largest counties of Scotland, situated near the centre of that kingdom, bounded N. by the counties of Inverness and Aberdeen, E. by Forfar and Fife, S. by Kinross, Clackmannan, and Stirling, and W. by Argyle; area, 2,836 sq. m.; pop. in 1851, 138,660. It is divided into the highland and lowland districts, the extent of the former being much the greater; and these are again subdivided into the ancient and popularly known divisions of Monteith, Athole, Strathearn, Breadalbane, Rannoch, Stormont, Perth proper, Gowrie, Balquhidder, and Glenarchy. The chief towns are Perth, Crieff, and Dunblane. The principal rivers are the Tay, the basin of which comprises nearly the whole county, the Forth, Earn, and Teith. The chief lakes are Loch Tay, Loch Ericht, Loch Rannoch, and Loch Katrine, all remarkable for the beauty of their scenery. Some of the mountains of the Grampian chain in Perthshire are among the highest in the island, three of them being nearly 4,000 feet above the sea. The extensive valleys called "straths" are very remarkable, and also the glens, the best known of which is Glen Tilt. The soil is mostly deep rich clay. There are some manufactures, but Perthshire may be regarded as an agricultural county. The land under crops is estimated at ¼ of the whole area. The fisheries on the Tay are very valuable. Perthshire returns two members to parliament, one for the county and one for the city of Perth.

PERTZ, Georg Heinrich, a German historian, born in Hanover in 1795. He was educated at the university of Göttingen. In 1819 he published a "History of the Mayors of the Palace under the Merovingians," which attracted the attention of Baron Stein, who soon after associated its author in his own project of a collection of the German historians of the middle ages. Pertz now undertook a series of journeys through Europe for the purpose of exploring libraries and museums. In 1832 he became a member of the Hanoverian representative chamber, and in the same year established the "Hanoverian Journal." He was made a privy councillor of the court of Berlin in 1842, and became director of the royal library in that city and member of the academy of sciences. His great undertaking is the editing of the *Monumenta Germaniæ Historica* (13 vols., 1826–'56).

PERU. I. The capital of Miami co., Ind., on the Wabash river and canal, and on the Toledo and Wabash and Peru and Indianapolis railroads, 75 m. N. from Indianapolis; pop. in 1860 estimated at 3,500. It is the business centre of a rich agricultural district, and has a valuable trade. There are a handsome court house, a gaol, 2 newspaper offices, 1 flour mill, 1 woollen factory, 1 distillery, 2 founderies, and 6 churches, viz.: 1 Baptist, 1 Episcopal, 1 Methodist, 2 Presbyterian, and 1 Roman Catholic. II. A city of La Salle co., Ill., at the head of navigation on the Illinois river, 60 m. above Peoria, on the Chicago and Rock Island railroad, 100 m. from Chicago, and about 1 m. from the junction of the Illinois central railroad with the Illinois and Michigan canal; pop. in 1860, 3,134. It is healthfully and handsomely situated, surrounded by fine scenery, and enjoys a very active business. The river furnishes extensive water power, and it has become one of the principal manufacturing towns of the state. Coal abounds in the vicinity. In 1857 the arrivals were 291, and the amount of steam shipping owned in the place was 4,700 tons. The receipts of lumber were upward of 10,000,000 feet, and 337,000 bushels of wheat, 625,000 of Indian corn, 161,000 of oats, and 48,000 bbls. of flour made in the city, beside immense quantities of coal, were exported. It contains a number of manufactories and a large ship yard, dry dock, and marine railway. There are also 2 banks, 3 hotels, 3 weekly newspapers, and 6 churches, viz.: 1 Congregational, 1 Episcopal, 1 Lutheran, 2 Methodist, and 1 Roman Catholic.

PERU, a republic of South America, bounded N. by Ecuador, E. and S. by Brazil and Bolivia, and W. by the Pacific ocean, extending from lat. 3° 35′ to 21° 48′ S., and from long. 65° 10′ to 81° 30′ W.; extreme length about 1,250 m., breadth 750 m. in the N. and 60 m. in the S.; area about 500,000 sq. m. The republic is divided into 11 departments, and 2 provinces which have the organization of departments. The departments are subdivided into 61 provinces, the provinces into 625 districts, and the districts again into parishes. The departments, with their capitals and population (not counting Indians) in 1853, were as follows:

Departments.	Population.	Capital.
Amazonas	39,074	Chachapoyas.
Anchas	155,779	Huaras.
Arequipa	121,585	Arequipa.
Ayacucho	129,921	Ayacucho.
Cuzco	346,211	Cuzco.
Huancavelica	76,198	Huancavelica.
Junin	245,722	Cerro de Pasco.
Libertad	202,662	Truxillo.
Lima	180,928	Lima.
Moquegua	61,440	Tacna.
Puno	245,681	Puno.
Callao, province	8,352	Callao.
Piura, "	74,872	Piura.
Total	1,887,920	

The statistical accounts recently published by Mr. G. Davila Condemarin, of the university of Lima, represent the area as 512,122 sq. m., and the population 2,500,000, viz.: of Spanish descent, 900,000; descendants of Indians, 1,400,000; negroes and mixed races, 200,000. —The sea coast of Peru stretches along the Pacific for about 1,500 m., from the mouth of the river Tumbez on the N. to that of the Loa on the S. Its general character is bold, with deep water close to the shore, in some places 70 or 80 fathoms within a short distance of the cliffs. About 300 m. of the N. extremity is broken by bays and headlands, and the remainder of the coast forms three successive and almost straight lines, running respectively about S. S. E., S. E., and S. The northern part however is not so bold as the southern, and has a greater proportion of sandy beach; but high land is always seen at a little distance inland. In its whole extent there are but few ports of any consequence, many of them being open roadsteads, or at least but very imperfectly sheltered. The bays of Callao and Payta are the most secure anchorages, and most frequented by foreign shipping, the latter being a favorite resort for American whalers. The most important islands upon the coast are those in the neighborhood of Pisco, more particularly the Chinchas (see CHINCHA ISLANDS); the island of San Lorenzo, which forms the harbor of Callao; and the Lobos islands, which lie between lat. 6° and 7° S., and like the Chinchas are covered with extensive deposits of guano. (See LOBOS.) There are no hidden dangers near any of these islands, and like the coast they have deep water close to the shores. Along the whole coast the swell rolling in from the Pacific breaks in a heavy surf, which renders landing in most places dangerous, and often impossible for boats. In exposed positions rafts called *balsas* are used by the natives for landing or embarking goods or passengers. In the N. these rafts are formed of logs of light wood lashed together, with a raised platform upon which the cargo is placed; and where the surf is very heavy, they are made of bundles of reeds. Along the S. coast the platform is supported upon inflated skins.—The most remarkable natural feature in Peru is the vast chain of the Andes, which traverses the country in a general S. S. E. and N. N. W. direction. It here forms two parallel ridges, the W. of which is sometimes distinguished as the Cordillera, while the E. retains the name of the Andes. They are connected by several transverse branches, and where the one is highest the other is most depressed. The E. ridge preserves its grand character from Bolivia to lat. 13° S., where it loses it, and N. of the Nevada de Sacantahi no snow-capped mountains occur. In the W. chain, near lat. 15°, a considerable portion of the range is covered with snow; S. E. of Lima the Taldo de Nieve rises above the snow line, and about lat. 11° the summit of La Vinda and several others are nearly 16,000 feet in height. Between La Vinda and Chimborazo in Ecuador none of the summits of this chain attain the snow line. The W. ridge is broader, wilder, and more rugged, and its summits are less pyramidal than those of the other, which terminate in slender sharp peaks, like needles. (See ANDES.) The W. ridge forms the water-shed between the rivers which flow to the Atlantic and those which reach the Pacific. All the waters of the E. declivity work their way through the other range to the Atlantic, while there is no instance of the Cordillera being intersected by a river; a remarkable fact, because in S. Peru and Bolivia it is the lower chain. The rivers of Peru that fall into the Pacific are all short, shallow, generally rapid.

and useless for navigation. The great rivers of the country all unite in forming the principal branch of the Amazon. They are generally of considerable depth, and in the course of time will doubtless be navigated by steamers from the Atlantic ocean. The chief streams are the Marañon, Huallaga, Ucayali, and Purus, the last of which forms part of the boundary line between Peru and Bolivia. With the exception of Titicaca, the lakes of Peru are small. Lauricocha is the source of the river Marañon; Chinchaycocha gives rise to the river Jauja; and Urcos is a small lake to the S. of Cuzco. Lake Titicaca is 115 m. long and 46 m. broad, contains many islands, and is situated 12,200 feet above the level of the sea.—The tract called *la costa*, between the steep ascent of the Cordillera, or W. Andes, and the Pacific, varies in width from 10 to 60 m., and slopes toward the ocean with a very irregular surface and rapid descent, furrowed by a number of deep depressions or gullies, which run from the mountains to the sea. These gullies are generally traversed by rivers, most of which are dry during a great part of the year. Rain never falls in the lower part of this region, and vegetation does not extend beyond the banks of the streams. The ridges between the rivers are complete deserts, varying in breadth from 10 to 20 m. The surface is very uneven, and is covered with hillocks of considerable size, composed of fine, light yellow drift sand, which is often driven about with great velocity by the wind and ascends in columns to the height of 80 or 100 feet. All traces of a path between the river valleys are thus obliterated, and no stranger can travel from one to another without a guide, who generally directs his course by the stars at night, and by the wind during the day, which always blows from the south. The region called *sierra*, or highlands of Peru, begins where the rainless district terminates, about 7,000 feet above the level of the sea, and extends from the Cordillera to the chain of the Andes. These chains are generally about 100 m. apart, and between them lie the table-lands, naturally distributed into regions differing widely in character. The chief of these are the heights of Pasco and Cuzco, and the valleys of the Jauja and the Marañon. The first lies between lat. 10° 30' and 11° S., and has a general height of 14,000 feet; it is traversed by chains of hills from 500 to 1,000 feet high, and has everywhere a rugged and forbidding aspect. The table-land of Cuzco extends about 100 m. each way. At the city of Cuzco, in lat. 13° 30' S., it has an elevation of 11,380 feet above the sea, but sinks rapidly toward the N., so that upon the banks of the Mantaro it is probably not more than 8,000 feet high. The valley of the Jauja adjoins the table-land of Pasco, descending rapidly S. for about 100 m., and in its general character resembles Cuzco. The valley of the Marañon extends between lat. 5° and 10° S., and is for the first 100 m. little more than a narrow gorge descending rapidly; it then becomes for 200 m. a wide and fertile country, having a mean height of about 3,000 feet above the sea. The most valuable part of the Peruvian territory, however, is the *montaña*, or wooded region, which lies to the E. of the Andes, extending from their E. declivity to the boundaries of Brazil and Bolivia. This region is watered by the Huallaga, Ucayale, Marañon, and many tributary streams. It is sometimes called Pampas del Sacramento, or Collena, or the "Land of the Missions," in consequence of the Jesuits having established several missions in it shortly after the conquest of Peru. There are extensive plains traversed by hills of inconsiderable height, the whole covered with one dense forest of luxuriant growth.—The geological character of Peru, except in particular localities, has not been well examined. Red sandstone is met with both on the coast and in the interior, often accompanied by vast deposits of salt. Granite and porphyry appear on the coast and in the highlands; and the commonest rocks on the sierras are trachyte, augite, porphyry, and diorite. Between Lake Titicaca and Cuzco, the more elevated ground bordering the valleys is formed chiefly of clay slate; and in the neighborhood of Arequipa, and from thence to Lake Titicaca, the soil is volcanic. In the province of Tarapaca, and in the neighborhood of Iquique, there is an extensive deposit of salt, nitre, and nitrate of soda; and the sandy region over which it extends, between lat. 19° and 22° S., is a complete desert. In many parts the houses are built of blocks of salt. In the coast district earthquakes are frequent, and sometimes very destructive. It is estimated that the coast of Peru has risen 85 feet since it was first inhabited. Since the great earthquake of 1746, the coast about Callao, which was raised upon that occasion, has been gradually sinking. The water courses further inland, toward the base of the mountains, furnish proof of great natural convulsions, many of them which exhibit the wear of centuries being now dry. It has been already stated that the region bordering upon the coast is a barren desert; but in the gullies, where there is sufficient water to irrigate the ground, abundant crops are produced from the sandy soil, which the cultivators manure with guano. Some of the highlands are exceedingly fertile; and the territory E. of the Andes is said to be among the richest in the world.—Peru has four climates: 1, that of the coast, upon a portion of which rain has never been known to fall, and on the greater part of which a shower is considered very remarkable; 2, that of the sierras, or highlands, which is mild and variable, with moderate rains; 3, that of the Cordillera and Andes, which is exceedingly cold; and 4, that of the territory to the E. of the Andes, which is warm and damp. The first climate, or perfectly rainless region, terminates at about 400 feet above the level of the sea, and from thence to an elevation of 7,000 feet extends a tract periodically refreshed by sea vapors or drizzle, called *garua*. These vapors continue from May to November, when the country bordering the coast desert becomes covered with vegetation. About Lima, 600 feet above the level of the sea, this vegetation is most abundant during the months of July, August, and September. Toward December, when the dry season may be reckoned to have set in, the weather, except for an interval at noon, is for the most part cool and delightful. The cold current which runs along this coast from the seas adjoining Cape Horn, the temperature of which is on an average 8° lower than the mean annual temperature of the atmosphere at Callao, contributes greatly to moderate the heat of the climate on the shore of Peru. The mean heat at Callao, in lat. 12° 4′, does not exceed 60°, and Humboldt states that he saw the thermometer as low as 55°. At Lima, in almost the same latitude, 7 m. inland from Callao, and 600 feet higher, the thermometer never falls below 60° in winter, and seldom rises in summer above 80°. The hottest day ever known in Lima was in Feb. 1791, when the thermometer rose to 96°. In Piura, the extreme N. province of Peru, the temperature ranges in summer from 80° to 96°, and in winter from 70° to 81°. The situation of the coast region, placed between the influences of the ocean current on the one side and the lofty mountains on the other, makes the climate temperate, as the breeze is cooled by either the sea or the Andes. During the dry season on the coast heavy rain falls in the interior, upon the W. slopes of the Cordillera and the tablelands, especially in the months of January, February, and March, and copious streams pour down to fertilize the ground lying upon the river banks. During the greater part of the year the winds upon the coast blow from the S., varying from S. S. E. to S. W.; but in the winter months N. breezes are occasionally met with. At some distance from the shore the S. E. trade wind prevails, but with greatest strength in winter. Lightning is sometimes seen on the coast of Peru, but thunder is never heard, and storms are quite unknown. In the 2d climate, in the district of the sierras or highlands, there is a considerable range of temperature between the rain line, at about 7,000 feet above the sea, and the snow line, which varies in height according to latitude. About 9,000 feet above the sea the average temperature is about 60°, varying little throughout the year, and the seasons are only distinguished as the wet and the dry, the former of which lasts from November to May. The 3d climate occurs in a district covered with perpetual snow. The 4th climate is entered after descending the E. face of the Andes and arriving at the plains and undulating country which extend to the boundaries of Brazil and Bolivia. The climate of this region is warm and moist; but the heat is not so great as might be expected in a country lying so close to the equator. The forests prevent the rays of the sun from reaching the ground; and the moist winds which blow from the Atlantic, over the plains watered by the Amazon and its tributaries, are stopped in their progress toward the Pacific by the Andes, and accumulate clouds which descend in heavy rains accompanied by storms of lightning and thunder. These copious rains cause such an excess of moisture, that the region is very unhealthy, and few individuals among the Indian tribes scattered along the banks of the rivers reach the age of 50 years.—The mineral productions of Peru, more particularly the precious metals, have been famous ever since the discovery of the country. Gold is found in many places, and nearly all the mountain streams wash it down in small particles. The mountains are interspersed with veins of gold and silver ores, and with copper and lead. In many places gold is found in quartz. The silver ore is particularly rich, frequently yielding from 5 to 50 per cent. This ore constitutes the great mineral wealth of the country, and presents itself in all forms and combinations, from the pure metal to the lead ore mixed with silver. It is found at the highest elevations yet reached. Quicksilver is also found, but in small quantities. The only quicksilver veins yet discovered of any magnitude are at Huancavelica, and on the Ucayale river. The Andes are very rich in copper ore; but it is extracted only from their W. ridge, as the difficulty of transport from the other to the coast is too great to make the working of the mines profitable. The lead and iron mines are not worked. Mining in Peru is still in a very backward state. The great height at which most of the mines are situated, the want of timber, the impossibility of transporting machinery over such roads, and the high price of the necessaries of life, present great difficulties in the way of improvement. The silver produced between 1630 and 1803 has been calculated to amount to $1,232,000,000. In 8 years (1826–'33) the silver coined at Lima alone amounted to $20,000,000. Humboldt estimates the average annual yield of the gold and silver mines in Peru at $5,300,000. In 1825 some English miners discovered good coal at Cerro de Pasco, and lately it has been found 18 m. S. from Tumbez. Not far from Arica, brown coal is found on the coast; and in the province of Tarapaca there is a subterranean forest, the wood of which affords excellent fuel and is used extensively in the preparation of saltpetre.—Peru is exceedingly rich in vegetable productions; and each of its natural regions has its own flora. The coast district has not many plants; but E. of the Andes the species are exceedingly numerous. Many species of medicinal herbs, and a great variety of aromatic balsams, oils, and gums, are produced. Trees and shrubs which yield 7 different kinds of wax are known; and according to Peruvian writers this territory is a new world in itself. Almonds, ginger, the balsam of copaiba, gum copal, &c., are all said to abound. On the montaña and the W. slopes of the Andes are produced the cabbage palm, the cocoanut, the chocolate nut, the cotton shrub, the pineapple, turmeric, plantain, and sugar cane, beside some trees that have only Peruvian appellations. The *coffea racemosa* is found in the interior, and the berries are used in the same way as those of the cultivated species. The large-flowered jasmine and the *datura arborea* are abundant in the vicinity of Lima, and are much used by the women for wreaths and for braiding in their hair. No fewer than 24 species of pepper and 5 or 6 of capsicum are reckoned natives; there are several species of *solanum*, or plants of the potato genus, and the potato commonly called the Irish was originally brought from Peru. Tobacco and jalap are abundant in the groves at the foot of the mountains; and many of the flowers cultivated in greenhouses and gardens in other countries grow wild in the forests. Cotton is found in great abundance in a wild state on the banks of the Amazon and its tributaries. Among the numerous shrubs which clothe the highlands, the different species of cinchona or Peruvian bark are the most valuable. It is scattered along the skirts of the Andes over an extent of 2,000 m., at an elevation of from 2,800 to 9,500 feet, and therefore thrives in a great variety of climates. On the E. declivity of the Andes it forms a continued forest for many miles. Caoutchouc is procured from the inspissated juice of a variety of different plants. The tree ferns range between 1,500 and 5,000 feet above the sea; beyond the height of 10,500 feet arborescent vegetables disappear; between 6,500 and 13,500 feet the alpine plants are found; species of the *Winteria* and *Escallonia* occur between 9,200 and 10,800 feet, and form scrubby bushes in the cold and moist climate. —There are extensive tracts on the W. side of Peru in which life seems to be almost wholly extinct. Among the wild animals of the country are the puma, jaguar, bear, deer, wild boar, fox, skunk, armadillo, sloth, and several species of monkey. The Peruvian sheep is the most valuable indigenous animal of the country. There are 4 varieties, the llama, alpaca, guanaco, and vicuña. The Spaniards introduced the European sheep into the country, and flocks of 50,000 to 100,000 may now be met with in the highlands. They also introduced horses, horned cattle, and asses; and the mule is now the ordinary beast of burden. In the valleys and toward the coast the imported animals have thriven, but on the heights they are much degenerated in size. Alligators are found in the rivers, and seals are very common along the coast. There are numbers of tortoises, and several species of serpents, but the latter are not often seen. The shores of Peru are frequented by myriads of sea birds, and to them the world is indebted for the valuable manure called guano. In the days of the incas these birds were protected by law during the season of incubation. The common carrion vulture frequents the towns in great numbers, and there are 4 species of condor. Many parrots are found in the E. district. Hawks, falcons, owls, pigeons, and other birds are abundant; and all the domestic fowls have been introduced.—The inhabitants of Peru consist of Spaniards, various tribes of native Peruvian Indians, and negroes, and of every conceivable admixture of them all. The native Peruvians or Indians are exceedingly ignorant, but a few of them have risen to eminence, and display great ability. Some of the tribes cultivate the soil, and others are principally engaged in manufactures. The ranks of the army are recruited from among them, and in the war of independence they showed great bravery. In March, 1858, under Vivanco, at Arequipa, out of a regiment 600 strong, 540 were killed and wounded before they submitted to Castilla. The pure-blooded descendants of the Spaniards are much inferior in number to those of mixed race. They are fickle and incapable of much mental labor, and addicted to cock fighting and all sorts of gambling. The women are remarkable for their personal attractions, elegant taste, natural cleverness, and pleasing manners; but they lose their bloom at an early age. The negroes are altogether confined to the towns near the coast and to seaports; with the mulattoes, &c., they form a very turbulent and unruly portion of the community.—Agriculture is not much attended to in the maritime districts, and Lima and many other towns near the sea depend upon imported provisions, which are chiefly brought from Chili. In the plains of Caxamarca large crops of barley and wheat are raised, the latter yielding from 18 to 21 fold. Between the elevations of 2,000 and 10,000 feet the fruits and cereals of the temperate climates are cultivated; but as no carts or wagons can travel these regions, and there exists no means of transporting produce to the country below except on the backs of mules, only sufficient grain is raised to supply the immediate wants of the district where it is grown. The manufactures of Peru are inconsiderable. Some cotton and coarse woollen fabrics, straw hats, mats, and a few other articles are made. Tanning, dyeing, soap making, distilling, and some other manufactures are carried on. Gold and silver filigree work and lace are made at Lima.—The principal exports are the precious metals, guano, nitrate of soda, wool, cotton, hides, Peruvian bark, sugar, olive oil, pisco (a spirit made chiefly in the neighborhood of the place from which it takes its name), and some wine of excellent quality. In 1854, 244,400 tons of guano were shipped, and it is calculated that the country now has enough of this manure to permit the exportation of 100,000 tons annually for 250 years. The imports consist of woollen, cotton, and linen goods, machinery, cutlery, earthenware, provisions, &c. The trade of Peru with other countries was as follows in 1853:

Countries.	Imports.	Exports.
Great Britain	$4,606,290	$8,818,755
France	1,888,780	1,441,605
Chili	654,000	497,485
United States	586,025	4,883,880
Hamburg	486,825	214,815
China	289,495	....
Ecuador	195,825	....
Spain	162,865	228,995
Antilles	....	264,240
Other countries	212,775	516,080
Total	$9,087,880	$16,865,805

In 1856, 871 vessels with an aggregate burden of 219,215 tons entered the ports of Peru from Great Britain and her possessions, importing goods to the value of $17,421,200; and 77 vessels, with an aggregate burden of 34,056 tons, cleared directly for the same destinations, taking exports to the value of $6,723,200. In the same year 61 vessels, tonnage 31,967, entered from French ports, and 33, tonnage 16,376, sailed with return cargoes, the value of the imports being $4,054,600, and of the exports $5,567,600. In 1853 the merchant vessels registered in the different ports of Peru numbered 187, tonnage 25,228. Ship building is not carried on, and the greater part of the vessels carrying the Peruvian flag are old and only fit to make voyages upon a coast where storms are quite unknown. They are principally craft from the United States and different countries of Europe that have been condemned and sold upon the S. W. coast of America for unseaworthiness. The internal trade of the country is very limited. Railroads have been opened between Tacna and Arica, Lima and Callao, and Lima and Chorillas, a fashionable watering place agreeably situated on the coast a few miles S. of Callao; but except upon the table-lands there are few roads of any description.—Education is in a low condition in Peru, but symptoms of improvement are apparent. The education of the lower orders is almost completely neglected, and in the interior of the country it is sometimes difficult to procure men qualified for a public office by merely being able to read and write. The university of St. Mark at Lima, established in 1570, is the most ancient university in America, but is not very well attended. The established religion is the Roman Catholic, and but little toleration is extended to other creeds. The church is immensely rich; its head, the archbishop of Lima, has 4 suffragans, the bishops of Arequipa, Truxillo, Cuzco, and Huamanga. There are 1,800 priests, 720 monks, and 1,200 nuns. Beside the regular clergy, there are missionaries appointed for converting the aboriginal tribes.—In theory the government is based upon popular representative principles, but in practice it has degenerated into a military despotism. According to the constitution, the president is elected for 6 years. There is no vice-president, and in case of a vacancy occurring the president's place is supplied by the president of the executive council. The cabinet is composed of 4 ministers, namely, for foreign affairs, justice and religion, war, and finance. The congress is composed of a senate and chamber of deputies. Each department sends two members to the senate; and the chamber of deputies is composed of one representative for every 20,000 inhabitants, or for every fractional part above 10,000. The departments are governed by prefects under the direct authority of the president; and at the capital of each there is a *junta* formed of two members from each of its provinces. There is a supreme court at Lima, and superior courts sit at Lima, Cuzco, Arequipa, Truxillo, Ayacucho, and Puno. The judges are appointed by the president, but cannot be removed at his pleasure. Capital punishment has been abolished for political offences. By a law lately made, illegitimate children are entitled to a share of their parents' personal property. The land force consists of about 10,000 men, with an unusually large proportion of officers; and the naval force of one screw frigate, 7 other steam vessels of war, and a few smaller vessels. In 1857 the revenue amounted to $18,656,256, of which $15,296,952 was derived from the profits upon the sale of guano. In the same year the expenditure was $16,360,051. On Jan. 1, 1858, the national debt amounted to $46,451,387. The currency of the country is in a very unsatisfactory condition, and the attempts lately made to improve it have been too limited to afford relief. Counterfeit money is so plentiful that in trifling transactions it may be said to pass current; and the Peruvian coin is so much debased that the dollar is in reality worth little more than 80 cents.—The early traditions and history of Peru have been treated in the article INCA. About 1511 Vasco Nuñez de Balboa, the Spanish governor of a small colony in Darien, first learned from a native chief that there was a country to the southward where golden vessels were in common use, and where that metal was of as little value among the people as iron appeared to be among Europeans. Balboa raised a considerable force of Spaniards, and together with 1,000 Indians started to invade the promised Eldorado. The march across the isthmus, though only 60 miles, occupied 25 days; and when he came in sight of the Pacific he formally took possession of that unknown sea and all that it contained in the name and on behalf of the king of Castile. After penetrating about a degree further south he returned for reënforcements; but he was superseded in his command, and the attempt to reach Peru was discontinued. In 1519 the capital of the colony of Darien was removed from the Atlantic side of the isthmus to near the present site of the city of Panama, and shortly afterward an association was formed for renewing the attempt to explore and conquer Peru. Francisco Pizarro, who had accompanied Balboa on the former expedition, was at the head of this enterprise; and his colleagues were Diego de Almagro, an illiterate adventurer like himself, and Hernando de Luque, vicar at Panama. Luque supplied the greater part of the funds, while the others engaged to do the fighting. Pizarro sailed from Panama in Nov. 1524, in a small vessel with about 100 men; but after seeing enough of the country to be convinced of its wealth, he was obliged to return without accomplishing any thing. Having visited Spain, obtained a royal grant of the territory to be conquered, and procured recruits, among whom were his 4 brothers, he set sail again in Jan. 1531, with 3 vessels, 180 men, and 27 horses, leaving Almagro behind to collect reënforcements. Landing at St. Matthew's bay, about lat. 1° N., after they had been 14 days at sea, the adventurers plundered a town in the province of Coaque; and being reënforced by the arrival of about 130 men, they began building a town in the valley of Tangarala, calling it San Miguel. The empire of the incas was now distracted by civil war between the two brothers Huascar and Atahualpa, to whom their father Huayna Capac had bequeathed equal shares of his kingdom. Atahualpa had recently gained a complete victory over his brother and taken him prisoner, and was now encamped with his army at Caxamalca, whither Pizarro marched to meet him, in Sept. 1532, at the head of 177 men. Received with apparent friendship, he managed treacherously to make the inca captive, and massacred a host of Indians, whose number is stated as high as 10,000, without losing one of his own men. The Peruvian army fled in dismay. Atahualpa offered as the price of his liberty to fill the apartment in which he was confined with gold; but after the precious ornaments of the temples and palaces had been contributed in amount equal when melted down to more than $17,500,000, Pizarro caused his royal captive to be put to death, Aug. 29, 1533. The Spaniards now marched toward Cuzco, the Peruvian capital, their force having by this time been increased to nearly 500 men, one third of whom were mounted. They entered the city Nov. 15, after defeating the natives in a fierce battle, and proclaimed as inca a half brother of Atahualpa named Manco Capac; the captive Huascar had been assassinated by order of Atahualpa a short time before the latter's death. Pizarro now determined to build a new capital near the coast, and the valley of the river Rimac was selected as its site. It was founded Jan. 6, 1535, and called Ciudad de los Reyes, or "city of the kings;" its present name has been derived from that of the river, which the Spaniards softened into Lima. In the mean time Manco had not proved the ready tool which the conqueror expected to find him. Exasperated at the treatment he received, the young prince escaped from Cuzco and raised a native insurrection. That city was besieged by overwhelming numbers, who set fire to the houses with burning arrows and red-hot stones. One of Pizarro's brothers was killed; many of the Spaniards who resided on farms cultivated by the forced labor of the Indians were massacred; reënforcements were cut off; Jauja was also attacked, and Lima was threatened, but the Peruvians were at last obliged to raise the siege in order to go home and cultivate their fields, or starvation had surely overtaken them. During the progress of these events Almagro had led an expedition southward to conquer Chili, the Spanish monarch having granted to him in 1534 all the country for 200 leagues S. of that bestowed upon Pizarro; but after penetrating as far as lat. 30° S., and undergoing the most incredible sufferings, he returned to Cuzco, claiming that it fell within the limits of his grant. The dispute resulted in open war, and a battle was fought June 26, 1538, resulting in the defeat and capture of Almagro and his subsequent execution. The condition of the country was now deplorable. All the ancient institutions were overthrown, and the rights of Indians and Spaniards were equally disregarded. The conquerors had apportioned the land and inhabitants together as the spoils of victory, and the Peruvians were reduced to the worst kind of slavery, aggravated by the fact that there were often two or more white men each claiming to be master of the same serf. Thus Manco Capac had little difficulty in raising them to arms whenever he saw fit. Pizarro proposed, as a means of checking these disorders, to establish military settlements in the country, strongly fortifying the houses, and giving to each settler a certain portion of land and a certain number of serfs to cultivate it. Reports of his oppressions finally reached Spain, and in 1540 Vaca de Castro was sent out with the commission of royal judge to examine into the state of affairs, and if possible to improve it. In case of Pizarro's death, he was to produce his warrant as royal governor. But before he could reach Lima Pizarro had been assassinated by a band of conspirators led by the son of Almagro. The young Almagro proclaimed himself governor, collected a considerable force, and gave battle to Castro near Jauja, Sept. 16, 1542. Defeated after an obstinate struggle, he was made prisoner and put to death, and Castro applied himself with considerable success to improving the condition of the country. He was soon superseded however by Blasco Nuñez Vela, who came charged with the execution of some new regulations for the colony, the most important of which respected the condition of the Indians. It was declared that all slaves should be free on the death of their masters; that Indian vassals of the crown and slaves whose masters had used them ill or had taken part in the factions of Almagro and Pizarro should be free at once; and that the Indians should be moderately taxed, and should not be forced to labor where they did not choose. These measures raised a storm of discontent, and the colonists looked to Gonzalo Pizarro, the last of that family now left in Peru, as their only hope. Gonzalo accordingly assumed the title of procurator-general of Peru, and, favored by the rashness of the viceroy, who was finally deposed by the *audiencia*, soon collected a formidable force, entered the capital, and assumed regal state. The news of these proceedings caused great consternation in Spain, and Pedro de la Gasca, who, though a member of the priesthood, had distinguished himself both as a soldier and a statesman, was sent out to draw the people back to their allegiance. He was invested with all the powers of the sovereign. In the mean time Gonzalo had seized the forts upon the isthmus of Panama in order to intercept any force from Spain, but no danger was apprehended by his officers from a poor priest who came without a retinue. By his promises of pardon to all who should join him, Gasca gained possession of the fleet at Panama in Nov. 1546, and afterward by the same inducement succeeded in raising a considerable force, with which he sailed for Peru in April, 1547. He was received with great enthusiasm. Gonzalo retreated from Lima, and afterward gained a victory over some royalists; but Gasca raised a force of 2,000 men, the largest European army that had yet been assembled in South America, and followed him to Jaquijagua, where, his troops deserting, he was made prisoner, and shortly afterward executed. The war having been brought to a close, Gasca turned his attention to establishing the government of the country upon a more satisfactory footing than had hitherto been attempted. He left Peru in Jan. 1550, and arrived in his native country after an absence of 4 years. With a few trifling exceptions, the colony remained quiet for many years, and the authority of the Spanish crown was completely established. The empire of the incas, with some slight alterations of boundaries, became one of the 4 viceroyalties of Spanish America. In 1718 the province of Quito was separated from it and annexed to the newly created viceroyalty of New Granada. The Peruvians under Tupac Amaru, a pretended inca, rebelled in 1780, but were easily subdued. In 1788 the provinces of La Plata, Potosi, Charcas, Chiquitos, and Paraguay were separated from Peru to form the government of Buenos Ayres; and Guatemala, Venezuela, Caracas, Cumana, and Chili were formed into separate administrations. In the war of independence, Peru was the last of the Spanish American possessions to rebel against the mother country, and the Spanish forces remained in it unmolested for some time after they had been expelled from the neighboring colonies. In 1820 Gen. San Martin entered the country at the head of an army of Chilians and Buenos Ayreans, and took possession of the capital. After a succession of victories, the Spaniards were compelled to retire to the interior. The independence of Peru was declared July 28, 1821, when San Martin was proclaimed protector. He afterward became unpopular, and in Feb. 1824, Bolivar was made dictator. The Spaniards maintained the contest with great obstinacy, and it was not until their defeat at Ayacucho that they were finally expelled. Bolivar resigned the dictatorship in 1825, after having matured his plans for separating the S. and S. E. provinces to form a new republic which adopted his name. A revolution took place in 1826, when the constitution adopted by Bolivar was abolished, and a new one framed, founded upon that of the United States. In 1836 Santa Cruz, president of Bolivia, taking advantage of an invitation from some disaffected parties in Peru, entered the country with an army, and succeeded in reducing it after several sanguinary engagements. Santa Cruz was proclaimed supreme protector, and N. Peru, S. Peru, and Bolivia were united in one confederation. The protector's troops were defeated at Yungay in 1839, and the confederation brought to a close, when Peru and Bolivia returned to their previous forms of government. A congress assembled, and Gamarra, who then governed provisionally, was appointed president. Gamarra was killed in battle in Bolivia in Nov. 1841, and Menendez, president of the council of state, succeeded him, but was forcibly deposed in Aug. 1842, by Gen. Forico. A series of civil wars now ensued, and the country passed successively into the hands of Vidal, Figuerola, and Vivanco. Gen. Don Ramon Castilla brought these struggles to an end in 1844, and replaced Menendez in power; when, a congress being called to choose a president in accordance with the constitution, Castilla himself was elected. He took possession of the government, April 1, 1845, and for 6 years order and peace were maintained. In 1851 Gen. Rufino José Echenique was elected president. His government was accused of the grossest frauds, and Castilla took advantage of the dissatisfaction of the people to stir up a revolution in the south. After several battles, Castilla gained a complete victory over Echenique's troops near Lima in the early part of 1855. The effects were decisive, and Peru was placed at his disposal. Castilla was not allowed to enjoy his power long in peace, for Vivanco incited an insurrection against him, and gained over the commanders of all the ships of war except a small steamer which was protected by the mole of Callao, and another which happened to be in China at the time. The fleet threatened to take Callao, and Castilla, alarmed for its safety, raised a force of nearly 400 Europeans and North Americans under the command of an artillery officer named Smith, who had already taken part in all the battles that had placed the president in authority. This force garrisoned the fort of Callao, and repulsed Vivanco's attack with such severe loss that he retired to Arequipa, a place which had always been attached to him. His fleet kept possession of the sea, and at one time held the Chincha islands. On Jan. 24,1858, two American vessels, the Lizzie Thompson and Georgiana, were captured while loading guano on the coast of the province of Arequipa, by a small steamer of Castilla's; and several other ships were subsequently seized under similar circumstances. Though there are extensive deposits of guano in other places, the laws of Peru only permit it to be exported to foreign countries from the Chincha islands. The ships in question were furnished by an officer of Vivanco's with permits to load at the places where they were seized; but although that chief was at the time in possession of the surrounding territory, the government of Peru refused to acknowledge them as any authority. The ships were removed to Callao, where they were confiscated and both captains and the mate of the Georgiana imprisoned; but they were released upon security after being confined for 8 days. The Peruvian government have since steadily denied all redress, and their refusal to pay $150,000, the amount claimed by the owners of the Lizzie Thompson and Georgiana, to indemnify them for their losses, led to the withdrawal of the U. S. minister from Lima in the autumn of 1860. Arequipa was taken by assault by Castilla in March, 1858, after a most obstinate and gallant defence, in which Vivanco had about 8,000 of his men killed and wounded. Though slavery was abolished in Peru by the charter of independence, it still existed till Castilla freed the slaves by proclamation in 1855. When the Spaniards conquered the country, they subjected the Indians to a capitation tax, which, although the revolutionary battles had been mainly fought and won by them, was still continued till they were freed by Castilla. In 1859 and 1860 the port of Guayaquil was blockaded by a Peruvian force, and in the latter year Castilla landed troops and proclaimed Franco, a minion of his own, president of Ecuador; but the new ruler, having no means of enforcing his authority except those supplied by his ally, was shortly afterward obliged to leave the country. All efforts to overthrow Castilla's government having failed, an attempt was made to assassinate him while riding in the streets of Lima in Aug. 1860. Three months afterward a better planned attempt was made by the conspirators, and a company of soldiers led by their officers succeeded in entering his house early in the morning. Castilla, being aroused by his wife, managed to escape in his shirt to the street, when the soldiers who had been brought to assassinate him turned, by the order of a friend of Castilla, and shot their officers on the spot.

PERUGIA, a province of the kingdom of Italy, formerly of the Papal States, bounded N. by the provinces of Urbino e Pesaro, E. by Macerata and Camerino, S. by Spoleto, and W. by Orvieto and Tuscany; area, 1,447 sq. m.; pop. in 1853, 234,536. The entire surface of the province is covered with spurs of the Apennines, the main chain of which runs along the N. and E. frontiers. The Tiber flows through the middle of the province. Although the face of the country is generally hilly, there are many wide and fruitful plains, so that Perugia is considered one of the most fertile provinces of the Apennines. The chief cities are Perugia, Assisi, and Nocera. The lake of Perugia (anc. *Thrasymenus*) is in the W. part of the province, near the Tuscan border, 9 m. W. of the city of Perugia. Its height above the sea is 1,107 feet, its length 9 m., its breadth 7½ m., and its depth not over 30 feet. It contains the three islands of Polvese, Maggiore, and Minore. Near Passignano, on the N. E. side of the lake, is supposed to be the place of the battle fought in 217 B. C. between Hannibal and the Romans.—Perugia, the chief town of the province (pop. 18,301), is situated on a high hill, 984 feet above the sea, on the left bank of the Tiber. It is enclosed by walls in the form of a polygon. Of the churches, said to be over 100, the most important are the Duomo or cathedral, the church of San Francesco, and the church of San Domenico. Among the other public buildings worthy of mention are the town house, the old exchange, and the citadel, built by Pope Paul III. Perugia is a bishop's see, and has a university founded in 1320, with a library of 30,000 volumes, a botanic garden, a mineralogical collection, and a cabinet of antiquities. The manufactures, which are few, consist principally of soap, distilleries of brandy and liqueurs, silks, and woollens. Perugia (anc. *Perusia*) is not mentioned in history until 310 B. C., when it is spoken of as one of the most powerful cities of Etruria. It was engaged in several wars with Rome, but was ultimately obliged to succumb to its power. In 41 B. C. it became conspicuous in the civil war between Octavius and L. Antonius, the latter throwing himself into the city and sustaining a desperate siege. He was forced to capitulate, and Perugia was burned down, having been accidentally set on fire. It soon became again a flourishing city, was a place of much importance in the Gothic wars, subsequently became a free municipal town, suffered greatly from the contests of the Guelphs and Ghibellines, and finally of its own accord placed itself in the hands of Braccio da Montone. Pope Paul III. included it in the Papal States. In 1859 its revolted inhabitants were treated with exceeding severity by the papal troops, and in 1860 it was annexed to the possessions of Victor Emanuel.

PERUGINO, Pietro, an Italian painter, whose true name was Vannucci, the master of Raphael, born in Castello della Pieve, in the ancient district of Umbria, in 1446, died there in 1524. He received his first instructions in painting from artists of the Umbrian school, and at the age of 25 visited Florence, where he studied with great assiduity, and became the friend and fellow pupil of Leonardo da Vinci. Having painted here a number of works, including an altarpiece of the Assumption, now in the academy of fine arts in Florence, he returned about 1475 to Umbria, and established himself in Perugia, whence he acquired the name Perugino, by which he is commonly known. In 1480 he was invited by

Sixtus IV. to Rome to assist in decorating the Sistine chapel, and the frescoes executed by him there show that his style was then essentially Florentine. After his return to Perugia he resumed the feeling and manner acquired from his early Umbrian teachers, modifying their asceticism by an infusion of grace, and greatly improving in drawing and coloring. His frescoes in the exchange of Perugia are considered his principal work. Other pictures painted there "are remarkable," says Mrs. Jameson, "for the simplicity, grace, and dignity of his Virgins, the infantine sweetness of the children and cherubs, and the earnest, ardent expression in the heads of the saints." He was now one of the most popular painters of Italy, and undertook numerous works, many of which were executed by his scholars from his designs. Gradually he was induced by avarice to sacrifice his art to love of gain, and his pictures painted subsequent to 1505 are feeble, mannered, and monotonous, beside showing marks of careless and rapid execution. His reputation could not long hold out against this deterioration of style, and during the last 10 or 15 years of his life he may be said to have survived himself. His best period was between 1490 and 1505. His school was then numerous and celebrated, and among his pupils and assistants he numbered Raphael, who remained with him from 1495 to 1502. Perugino's works are found in every considerable collection in Europe, but those painted in his best manner are rare.

PERUVIAN BARK. See Cinchona.

PERUZZI, Baldassare da Siena, an Italian architect of the Siennese school, born in Volterra in 1481, died in Rome in 1536. The early part of his life was devoted to painting, and after executing some works in a chapel at Volterra, he went to Rome, where he painted some frescoes in the church of S. Onofrio, in that of San Rocco à Ripa, and in the fortress of Ostia. Subsequently he began the study of architecture, and became especially distinguished for his skill in architectural perspectives and scene painting. One of the best of his works was the Farnesina palace, so elegantly constructed that, according to Vasari, it "ought rather to be described as a thing born than as one merely built;" and so exquisitely adorned that when Titian first saw it, he could hardly be persuaded that the objects were not real. Peruzzi erected and embellished a large number of buildings and façades. In 1520 Leo X. appointed him to succeed Raphael as the architect of St. Peter's; but on the sacking of Rome in 1527 by the constable de Bourbon, Peruzzi was stripped of all his property, and it was with extreme difficulty that he escaped with his life to Sienna. Returning to Rome, he began the erection of the Palazzo Massimi, usually considered his masterpiece, but did not live to see it completed. His whole life was a series of misfortunes. He was poisoned by a rival architect from jealousy, and died in indigent circumstances. He was buried in the Pantheon near Raphael. He has been called the Raphael of architecture.

PESARO (anc. *Pisaurum*), a city of central Italy, capital of a district of the same name, in the legation of Urbino e Pesaro, and situated at the mouth of the Foglia, 19 m. N. E. from Urbino; pop. 18,000. It is fortified, adorned with magnificent churches, palaces, and other buildings, and has a public library, 2 hospitals, a foundling asylum, and a theatre. Several of the churches and convents contain valuable paintings. Delf, glass, and silk are manufactured. The figs which grow in the neighborhood are considered the best in Italy.—The city is first mentioned in history in 186 B. C., when a Roman colony was settled there. It was a flourishing town during the empire, was destroyed by Vitiges in the Gothic wars, was rebuilt in part by Belisarius, became prosperous under the exarchate of Ravenna, and was one of the cities of the Pentapolis.

PESCE, Nicola, or Cola, a Sicilian swimmer and diver, who lived about the end of the 14th century. He received the name of Pesce (the Fish) from his skill in diving and swimming, and was patronized and employed by Frederic, king of Sicily. Having been accustomed from his boyhood to dive for oysters and corals, he became so expert as to be enabled to remain under water longer than any other person on record, and the most fabulous stories were told of his feats. It was said that he was in the habit of passing whole hours under water and whole days in it, and of swimming from Sicily to the Lipari islands, carrying a leather bag containing letters and despatches. The story goes that Frederic wished him to dive off Point Faro, into the whirlpool of Charybdis; and as Pesce doubted whether to make the attempt, the king threw into the sea a golden cup. Pesce dived after it, and, after staying a long time under water, succeeded in recovering the cup, which he received as a gift along with a purse of gold. A second experiment, however, resulted in his death. Schiller's ballad of "The Diver" is founded upon this incident.

PESHAWER, or Peshawur, a province of British India, in the Punjaub territory, occupying the N. W. extremity of the Indian empire, bounded N. by the territory of Cashmere, E., S. E., and S. by Lahore, and W. and N. W. by the Afghan province of Jelalabad; area, 2,324 sq. m.; pop. about 500,000. The Khyber, Mohmund, Swat, and Khuttuk mountains form the boundary line on all sides except the E. and S. E., upon which the Indus flows. The province is exceedingly well watered by several streams, and the water is applied to purposes of irrigation by means of canals from which it is raised by Persian wheels turned by cattle, and by other contrivances worked by men. The climate is very hot in summer. The soil is naturally fertile; vegetation continues throughout the year, and two harvests are gathered. The principal crops raised are wheat, barley, maize, millet, ginger, turmeric, tobacco, and cotton, together with the greater part of the fruits and vegetables grown in both tropical and temperate regions, and a kind of rice called *bara*, the finest in the world. The road from Hindostan to Cabool and Khorassan by the Khyber pass leads through Peshawer; and the province being open to the inroads of the wild inhabitants of the mountains, the British maintain a regular military force of upward of 10,000 men along the grand trunk road between Lahore and Peshawer to hold them in check.—The capital, PESHAWER, is situated on the river Bara, in lat. 33° 59′ N., long. 71° 40′ E., about 18 m. E. from the E. extremity of the Khyber pass; pop. 53,295. It is surrounded by high mud walls, strengthened with bastions, and defended by a fort. When Peshawer was ruled by the Afghans, it contained 100,000 inhabitants; but after their defeat by Runjeet Singh he destroyed the fine houses of the chief citizens, desecrated the mosques, and laid the surrounding country waste. The exactions of the Sikhs were subsequently so heavy that its restoration was prevented, but since its occupation by the British all restrictions upon it have been removed, and the town has rapidly increased. About ¾ of the inhabitants are Mohammedans, and the remainder Hindoos. Peshawer was founded by the emperor Akbar. The present fortress was erected by Runjeet Singh.

PESTALOZZI, JOHANN HEINRICH, a Swiss teacher, and founder of the Pestalozzian system of education, born in Zürich, Jan. 12, 1746, died in Brugg, Feb. 17, 1827. His father was a physician of Zürich, his mother the daughter of a Protestant clergyman. By the death of his father when Heinrich was only 6 years of age, he was thrown entirely under his mother's care. Naturally of a feeble constitution, no effort was made to develop and invigorate his physical system; and he grew up awkward and clumsy. His temperament was highly visionary and speculative, and he was constantly distressed with an ambition to do something for the benefit of his country, and especially of the poor, while he possessed little executive ability and still less practical knowledge. His disposition was amiable, affectionate, and patriotic. His education was meagre, especially in the common branches (for he was tolerably familiar with the classics), when Rousseau's *Émile* fell into his hands, and led him to abandon the legal and historical studies which he had commenced, and set up for an educational reformer. By the advice of Tschiffeli, an intelligent but enthusiastic and impracticable farmer of Kirchberg, in the canton of Bern, he purchased a barren tract of land near Birr, and in 1767, in connection with a rich mercantile firm in Zürich, commenced a madder plantation, and erected a villa for himself, which he named Neuhof. Here he purposed to establish a centre for his educational and agricultural labors; but the madder plantation did not prosper; the villa was too costly for the estate; his assistants were unfaithful; and he himself was entirely incompetent for a business undertaking of such magnitude. The result was, that his Zürich partners withdrew their capital; but Pestalozzi resolved to continue his farming, and to combine with it a school for poor children. The school was opened in 1775, and soon had 50 pupils. His plan was to make it a manual labor school, employing the children in summer in field work, in winter in spinning and other handicrafts. Instruction was to alternate with labor in the summer, and in the winter the teaching, which was chiefly oral, was to be communicated while they were at work. The school did not succeed, partly because Pestalozzi was too good-natured to resist the importunity of the parents in demanding a compensation for the children's work far beyond its value; but mainly because he attempted to carry on the higher branches of manufacture, when the children whom he employed had not acquired sufficient skill to produce well even the commonest goods. In 1780 he was compelled to break up the school. He was at this time reduced to great extremities. His wife, who had pledged nearly her whole property for him, was suffering from a protracted illness, and they were often without money, bread, or fuel. It was under these depressing circumstances that his genius, ripened by suffering, began to display itself. Near the close of the year 1780 there appeared a paper from his pen in Iselin's *Ephemeriden*, entitled "The Evening Hour of a Hermit." It contained a series of aphorisms on education, and produced a decided effect in Germany and Switzerland. In 1781 appeared the first part of his *Lienhard und Gertrud*, a work which at once established his reputation as a writer, and the object of which was to enforce the importance of home education, and the evils of dissipation. It had a large sale, and excited much attention in Germany and Switzerland. It has been translated into most of the languages of Europe. The agricultural society of Bern awarded Pestalozzi their great gold medal and a vote of thanks. Offers were made him to remove to Italian Switzerland, to Austria, where Count Zinzendorf desired his aid, and to Florence, where the grand duke of Tuscany was about to give him an appointment; but, depressed in spirit, he preferred to remain at Neuhof, where his circumstances were not much improved. In 1782 he published *Christoph und Else*, a supplement to his "Leonard and Gertrude," but far less popular. Several other of his works of a philosophical character were published between this period and 1798. He also edited during a part of this time "The Swiss People's Journal," and projected a lunatic asylum and a reformatory institution, but neither went into operation. In 1792 he visited Germany, and formed the acquaintance of Goethe, Herder, Wieland, Klopstock, and Jacobi. In 1797 and 1798 the impending danger to his country from the French occupation roused his patriotic spirit, and he urged upon the people, in his "Journal," as well as in other publications, the importance of order, justice, and law, the promotion of education, and a return to the integrity and piety of their ancestors. The government offered him an office to quiet him, but he replied to their inquiry as to what office he would be willing to accept: "I will be a schoolmaster." He was accordingly about to open an educational institution in the canton of Aargau, when, in Sept. 1798, Stanz in Unterwalden was burned by the French, the entire canton laid waste, and a multitude of orphan children left homeless. Legrand, then at the head of the Swiss directory, called upon Pestalozzi to go to Stanz and take care of those destitute children. Here for 10 months he taught, fed, and trained 80 children, under the most difficult and distressing circumstances, a considerable number of them sick, and all suffering from scurvy and cutaneous affections. He would probably have died under his labors, had not the French, in their retreat, visited Stanz again, and turned the convent where Pestalozzi was teaching into a hospital. After a few months he obtained permission to teach in a primary school at Burgdorf, in the canton of Bern. A year later an attack of pulmonary disease compelled him to relinquish his labors, and in 1800, in conjunction with Krüsi, Tobler, and Buss, he opened an educational institution at Burgdorf. This school may be regarded as the first systematic attempt, on the part of Pestalozzi, to reduce to practice the principles of education shadowed forth in his "Leonard and Gertrude" nearly 20 years before; and it is remarkable that he should have attained his 54th year before putting in practice a system which had been fully formed in his mind for 20 years. It was the next year after the organization of this school that he gave to the world a full exposition of his educational views, in a work bearing the singular and hardly appropriate title of *Wie Gertrud ihre Kinder lehrt* ("How Gertrude teaches her Children"). This work had a wide circulation, and attracted not only private friends of education, but deputations from several of the European governments, to visit the institution at Burgdorf. In 1804 another revolution occurred in the government, and the castle at Burgdorf which Pestalozzi had hitherto occupied being wanted by the Bernese government, he was under the necessity of removing his school to Buchsee, where the government assigned him a monastery, close by Hofwyl, the estate of Fellenberg, who soon came to have a controlling interest in the management of the school. It was not long, however, before Pestalozzi found the methods of management introduced by Fellenberg so different from his own, that he accepted a proposal in 1805 to remove his institution to Yverdun. At first only a few of his teachers and pupils accompanied him, but half a year later the rest came. Here, though now in his 60th year, Pestalozzi entered upon the work of teaching with greater zeal than ever before, and with more decisive results. His system, as developed in his "How Gertrude teaches her Children," and his "Book for Mothers," which followed it, was gaining popularity in most of the countries of Europe; teachers were sent to him for instruction, and the Pestalozzian system was formally adopted by the Prussian and other German governments, while it greatly modified the method of Sagan in Austria, that of Jacotot in France, and that of Father Girard in Belgium. But dissensions soon sprang up among his teachers. Schmid, indispensable to Pestalozzi for his financial skill and executive ability, was haughty, stern, and overbearing in his manners toward the other teachers, and in 1810 an *émeute* occurred, which was only quieted by his leaving the institution. There was no one left who could fill his place; Pestalozzi himself had no skill in financial management or discipline, and in 1814 the downward tendency of the institution necessitated Schmid's return. In 1816, 12 of the teachers, unable to remain with Schmid, resigned at once; among them were Krüsi, Niederer, Blochmann, and Buss. This was followed by a 7 years' lawsuit, arising out of the pecuniary affairs of the institution, between Pestalozzi and Schmid on the one side and Niederer on the other. It was finally settled by arbitration. Meantime the school was losing ground; a poor school at Clindy, intended as a sort of appendage to the institution at Yverdun, was maintained for 5 years, but was finally relinquished. At length, in 1825, the Yverdun institution was broken up, and Pestalozzi, now in his 80th year, retired to the home of his grandson at Neuhof, where, 50 years before, he had commenced his first school for the poor. In 1818 a portion of his works had been collected by Schmid, and published by subscription, which yielded him a net return of about $10,000. After his retirement to Neuhof, with a mind still unbroken by adversity, he wrote his *Schwanengesang* ("Song of the Dying Swan") and *Mein Lebensschicksale als Vorsteher meiner Erziehungs-Institute in Burgdorf und Iferten* ("Fortunes of my Life, as Principal of my Educational Institutions at Burgdorf and Yverdun"), and delivered two or three lectures on education.—It is difficult for the reader, unfamiliar with the history of education, to understand how this man, whose whole life, considered in detail, seems to have been a succession of failures, should have exerted an influence so powerful as he evidently has upon the civilized world for the last 50 years; but the true explanation is, that in his educational theories he had brought to light great and abiding principles, and that his system was greatly better than his own exemplification of it. The principles developed in his works on education, though some of them perceived but dimly by himself, are the following: that education should proceed according to the laws of nature; that it is the duty of the teacher to assist this, by exciting the child to self-activity, and rendering him only a limited degree of assistance; that progress should be slow and gradual, but uninterrupted, never passing to a second topic till the first is fully understood; that the memory and the understanding should not be unduly cultivated, but all the faculties developed in harmony; that the peculiarities of every child and of each sex should be carefully studied in order to adapt instruction to them; that the elements of all knowledge are form, number, and language, and that these elements should be taught with simplicity and thoroughness; that the art of observing should be acquired, and the perceptive faculties well developed; that every topic of instruction should become an exercise for the reflective powers; that mental arithmetic, geometry, and the arts of drawing and modelling are highly important exercises for training, strengthening, and disciplining the mind and the faculties; that the laws of language should be developed from within, and the exercises in it made not only to cultivate the intellect but to improve the affections; that vocal music should be taught in schools, not by rote, but by a careful study of the elementary principles of music; that the proper method of instruction is not by question and answer, but, in the early stages of education, by dictation by the teacher and repetition by the scholar, and at a more advanced stage giving out problems by the teacher, to be solved by the pupil without assistance; that religious instruction should begin with the mother, that the filial feelings of the child should be first cultivated and directed toward God, and that formal religious instruction should be reserved to a later period, when the child can understand it; that despotic and cruel government in schools (which had been almost universally practised up to his time) is improper, but that artificial incentives to emulation are equally so; that the consciousness of increased intellectual vigor, and affectionate regard for the teacher, are the best stimulants to exertion; and finally, that the careful culture of the physical powers and the exercise of the senses are of very great importance to the complete development of the child. It was the office of Pestalozzi to educate ideas and not children; to combat the errors, prejudices, and abuses which were prevalent on the subject of education in the age in which he lived; to lay down correct principles, which others could carry out much better than he, and which have effected a complete revolution in the education of the young. —A list of Pestalozzi's works, collected by K. von Raumer, enumerates 40 distinct volumes, of which about 30 are devoted to educational topics; the remainder are philosophical or political. For an analysis of most of these, and extracts from several of them, see "Pestalozzi and Pestalozzianism," edited by H. Barnard, LL.D. (New York, 1859).

PESTH (Hung. *Pest*), the commercial and literary metropolis of Hungary, and capital of the central county of the same name, situated on the left bank of the Danube, opposite Buda, 135 m. E. S. E. by railway from Vienna; pop. about 95,000. Together with Buda it is also known under the name of Buda-Pesth (Hung. *Budapest*), both cities together constituting the administrative, and, according to the laws of 1848, also the legislative capital of the country. They are connected by a suspension bridge, one of the greatest works of the kind, commenced in 1840 under the direction of the English engineer Tierney Clark, and opened Jan. 5, 1849, being first crossed by the retreating Hungarian revolutionary army under Görgey, and immediately after by the Austrian army under Windischgrätz, both accompanied by heavy trains of artillery and ammunition. The towers of the bridge are 200 feet in height; the length of the central span is 670 feet, the entire water way 1,250, the width of the roadway 25, and of each footpath 6, the height of the platform above the river 45, and of the towers above the same level 120. The view from the bridge over the river and its banks, one of which, that of Pesth, is lined with a magnificent row of massive palatial buildings, and the other crowned by the high fortress of Buda and the surrounding mountains, is unsurpassed in beauty. But it is to the river and its islands, and principally to the picturesque environs of Buda, that the capital of Hungary owes almost all its natural attractions, Pesth being built on a sandy plain, destitute of any interesting feature. The town consists of 5 divisions, called the Inner, Leopold, Theresa, Joseph, and Francis towns. Of these the Inner town is the oldest or original part of the city, forming a quadrangle on the bank of the Danube facing the S. part of Buda and the Blocksberg (Gellért mountain). It is surrounded by the other divisions in a kind of semicircle, commencing with the Leopold town on the upper or northern bank of the Danube, and in the Francis town returning to the lower or southern. The Inner town and Leopold town contain the principal and most fashionable parts of the metropolis, among others the long and grand quay along the water side, above and below the bridge, with its row of high, massive, and brilliantly whitewashed buildings, some of them adorned with porticoes; the New, Joseph's, City Hall, and other principal squares, of which the former is one of the largest in Europe; the fashionable and commercial thoroughfares, the Waitzner (Hung. *Váczi*), Gentlemen's, and Bridge streets; the Dorothea, Wind, and other wide streets adorned with splendid private residences; the Parisian alley, a *passage* in the style of those of the French capital; the city hall, the county house, and other administrative public buildings; the city theatre, the national casino, the exchange, and the principal newspaper offices; and the largest hotels, some of which rival in elegance the finest establishments of their kind in continental Europe. The coffee houses of Pesth, most of which are attached to hotels, are especially commodious. Beside the above mentioned streets, the Waitzner road, Country road, Kecskemét road, and King's street are among the main thoroughfares of Pesth. Most of these, as well as other new streets, being wide and straight, the city is frequently annoyed by drifts of dust from the sandy environs, against which it is protected, however, on the N. E. by an extensive plantation, called the city grove, and forming the most frequented promenade. It is well paved, and lighted with gas.—Pesth contains some of the highest administrative or judicial courts of the country, among others the so called septemviral table, or supreme court of appeals, the royal table, and the central police office; the highest institutions of learning, the foremost of which is the university, one of the most richly endowed in the world, with a library of more than 70,000 vols., a botanic garden, a museum, an observatory, and a printing establishment (the last two in Buda); the national museum, which owes its origin chiefly to the munificence of Count Francis Széchényi and other Hungarian magnates, and contains rich collections of antiquities, coins and medals, works of art and literature, and natural and historical curiosities; a national theatre, which by the talents of its performers vies with the best stages of Vienna; the Hungarian academy or scientific society, founded by the diet in 1825, the principal object of which is the cultivation and scientific development of the Hungarian language; and numerous other national or private patriotic associations for the promotion of literature, art, commerce, or industry. There are large civil and military hospitals, poor and orphan houses, insane and blind asylums, a house of invalids, a workhouse, a *mont de piété*, a pension house for ex-officials, and numerous other benevolent institutions, some of which belong only to particular denominations. Of the schools, too, some are sectarian in their character, or belong only to a certain nationality, there being schools for Magyars, Greeks, Wallachs, Germans, Illyrians, Jews, &c., as well as common schools. One of the most renowned civil schools is the Piarist gymnasium. The principal military institution is the Ludoviceum. The largest military building is the "New Building," a barrack and artillery depot of enormous dimensions, built by Joseph II. for some unexplained purpose, and frequently used as a state prison, from which after the revolution of 1848–'9 some of the most distinguished Hungarian patriots were taken to the scaffold. The churches of Pesth are comparatively neither numerous nor conspicuous; those of the Roman Catholics exceed in number those of all other denominations together, the Catholics forming about $\frac{3}{4}$ of the population, the Jews $\frac{1}{8}$, the Protestants $\frac{1}{15}$, and the Greeks $\frac{1}{100}$. The German and Hungarian languages are chiefly spoken, and beside these the Slovakian, Servian, and other Slavic dialects.—The principal occupations of the inhabitants are commercial, trade being promoted by railways connecting the metropolis with the most flourishing parts of Hungary, as well as with the German provinces of Austria, by the active steam navigation on the Danube, which makes it one of the most important depots of commercial exchange between Constantinople and the West, and by four annual fairs, during which the city and its suburbs are filled for weeks with traders of various nationalities, Magyars, Germans, Jews, Slovaks, Poles, Ruthenians, Wallachs, Serbs, Greeks, Armenians, Croats, Transylvanian Saxons, and others, exchanging the produce or manufactures of their respective provinces, or of foreign countries. One of the most active branches of industry is the printing business, the publishing establishments of Pesth supplying Hungary with the most important productions of national Hungarian literature, with numerous works in German, Servian, Wallachian, Slovakian, Ruthenian, &c., and with numerous journals and periodicals. Of the daily newspapers published in 1861 the *Pesti napló* ("Pesth Diary"), *Magyarország* ("Hungary"), and the *Lloyd* (in German) are among the most conspicuous.—The origin of Pesth is ancient. The Romans had a colony on its site, called Transacincum. It is mentioned as a town in the history of the 11th century, and was destroyed by the Mongols in 1241, but having been rebuilt became flourishing at a later period, when Buda was made the capital of the kingdom. The diets and elections of kings were then held on the plain of Rákos, at a short distance from the town, in the open air, nobles, magnates, and priests assembling in arms, and dwelling under tents. After the battle of Mohács (1526), Pesth was for about 160 years in the hands of the Turks, until the conquest of Buda (1686) put an end to their sway in Hungary. At the beginning of the 18th century it was made a royal free city, and from that time its growth was continuous down to the national war of 1848–'9, interrupted only for a short time by a frightful inundation in March, 1838. Its great revolutionary day was March 15, 1848. The Hungarian national assembly was opened there July 5. The city was evacuated by the revolutionary government and army at the beginning of 1849, reoccupied by the troops under Aulich in April, and repeatedly bombarded by Hentzi during the siege of Buda in May, on which occasion about 60,000 of the inhabitants found refuge in the city grove, living there under tents. The Hungarian independent government established itself there and in Buda in June, but abandoned it in July. After the surrender of Comorn it witnessed the execution of Count L. Batthyányi (Oct. 6), of Csányi, Perényi, Jeszenák, and other distinguished patriots. At that time thousands of its inhabitants withdrew to the rural districts, and it was for a time comparatively deserted.

After the disasters of the Austrians in Italy, however, it again became the centre of national agitation, culminating in the assemblies of the county board, the commune, and the "national club," in Feb. and March, 1861.

PETAL, in botany, an organ of the flower which helps to compose the corolla. In every developed blossom are found two rows of leaves, the outer, generally green, called the calyx, the inner, usually colored and sometimes white, called the corolla. When both calyx and corolla are of the same substance and color, the rows of leaves are called the perianth, a term belonging properly to the liliaceous plants. Petals vary greatly in size, from very minute points to broad and expanded laminæ; they may be entirely free and fall separately, or be more or less united at their edges, forming what is called the monopetalous corolla. The office of the petals seems to be to guard the more essential parts from harm until after impregnation; they constitute the beauty of the plant, their tints being of all grades from delicate to magnificent.

PETARD, in artillery, a very short gun, formerly used for blowing down gates and other barricades. It was mounted upon a plank and secured close to the object to be burst open. Its length was only about 7 inches, and its bore at the mouth 5 inches. Its charge was from 9 to 20 lbs. of gunpowder. Petards are said to have been first used by the French Huguenots at the siege of Cahors in 1579. Various curious devices were employed as a protection against them, one of which, figured in Hanzelet's *Traités militaires* (1598), was a sort of trap in which the machine and those applying it were caught. Loose bags of powder exploded against gates are found to be equally effectual as petards.

PETCHORA, a river of European Russia, which rises in the western slopes of the Ural mountains, about lat. 61° 40′ N., long. 59° E., and flows into the Arctic ocean by many mouths in lat. 68° 20′ N., between long. 53° and 54° E., after a course of 900 m. After leaving the government of Perm, in which it rises, it passes through those of Vologda and Archangel by a very circuitous course, and many islands are formed by the stream separating and again uniting as it approaches the sea. Its principal tributaries are the Ussa, Ishma, and Tsylma.

PETEN, Lake of. See Guatemala.

PETER, Saint, one of the 12 apostles, born at Bethsaida in Galilee. He was a son of one Jonas or John, whence Christ calls him on one occasion (Matt. xvi. 17) by the surname Barjona, or son of Jonah. His original name was Simon. Before his vocation to the apostleship he had married and removed to Capernaum on the lake of Gennesareth, where with his brother Andrew he followed the occupation of a fisherman. It is probable that like Andrew he was a disciple of John the Baptist. It is related by St. John the Evangelist that the Baptist, standing with two of his disciples, saw Jesus pass by, and exclaimed: "Behold the Lamb of God!" whereupon the disciples followed our Lord and remained with him all that day. One of these two was Andrew, who had no sooner discovered that Jesus was the Messiah than he sought out his brother and brought him to our Lord. "And when Jesus beheld him, he said, Thou art Simon the son of Jona; thou shalt be called Cephas, which is by interpretation a stone." (John i. 42.) It is from the Greek word πέτρος, the equivalent of Cephas, that the apostle derived the name of Peter—a name which on a subsequent occasion Christ expressly gave to him, declaring: "Thou art Peter, and upon this rock I will build my church." (Matt. xvi. 18.) After their first intercourse with the Saviour Peter and Andrew returned for a season to their occupation of fishing, and were engaged in washing their nets when Jesus, shortly after the commencement of his ministry, walking by the sea of Galilee, entered into Peter's boat to avoid the pressure of the multitude. Peter had toiled all the night and had taken nothing; but at Christ's command he let down the net again and enclosed a miraculous draught of fishes, so that the net broke with the weight. He now received his call to leave all and become "a fisher of men," being with his brother Andrew the first chosen of the apostles. He seems beside to have been one of the most favored of the 12; he was one of the 3 who were selected to witness the transfiguration and to watch with the Saviour during the agony in the garden of Gethsemane. He frequently appears in the Gospels as the spokesman for his companions; he is often specially addressed by our Lord, and it is probable that Christ dwelt at his house in Capernaum. It is the opinion in fact of most, though not of all critics, that he enjoyed a certain preëminence among the apostles, upon which, coupled with the injunction given to him by the Saviour to feed his flock, and the declaration: "Thou art Peter, and upon this rock I will build my church," the Roman Catholics found the doctrine of the supremacy of the popes as Peter's successors. Protestant theologians however regard this preëminence as personal and not official, and conferring honor without any superior authority. The character of Peter, as displayed in the gospel narratives, is one that commends itself particularly to our interest and affection. Ardent, zealous, quick in his faith, and strong in attachment to his divine Master, he yet exhibits in a more marked degree than his fellow apostles the common failings of humanity. When Christ walked upon the sea of Galilee to meet his disciples whose ship was tossed with the waves, Peter with his leave walked toward him upon the water; but becoming afraid he began to sink, and cried: "Lord, save me." Jesus stretched out his hand and caught him, and rebuked his fears, saying: "O thou of little faith, wherefore didst thou doubt!" (Matt. xiv. 29–31.) Again, when Christ predicted his passion and death, Peter remonstrated with him, exclaiming: "Be it far from thee, Lord; this shall not be unto thee. But he turned and said unto Peter, Get thee behind me, Satan; thou art an offence unto me; for thou savorest not the things that be of God, but those that be of men." (Matt. xvi. 22, 23.) At the last supper during the feast of the passover, when our Lord washed his disciples' feet, Peter at first refused with great vehemence to permit his Master so to humiliate himself before him; but being told by him: "If I wash thee not, thou hast no part with me," he cried out: "Lord, not my feet only, but also my hands and my head." The same night, in reply to a boast of the apostle that he would lay down his life for his Master, Jesus said to him: "The cock shall not crow until thou hast denied me thrice." (John xiii.) The fulfilment of this prophecy, and the apostle's grief for his fall, as well as his rash zeal in the garden of Gethsemane, when he smote off the ear of one of those who came to apprehend Christ, are familiar events in the history of the passion. Peter was one of the first to whom the Lord showed himself after his resurrection. On a subsequent occasion he had been fishing all night with Thomas, John, James, Nathanael, and two others, and had caught nothing, when Jesus appearing on the shore bade them cast their nets on the right side of the ship, and it enclosed such a multitude of fishes that they could not draw it up. As soon as Peter knew it was the Lord, he threw himself into the sea in his impatience to come to him. Thrice assuring Christ, in answer to his questions, that he loved him more than the rest, he was commanded to feed his Master's sheep and lambs, and was then foretold the sufferings and death whereby he should glorify God, when he should stretch forth his hands, and another should gird him, and carry him whither he would not. (John xxi.) From this time his character seems to have been changed by an infusion of that strength and dignity which it previously lacked. He is frequently mentioned in the Acts, and always appears as a bold and unflinching preacher of the new faith. He preached to the multitude in Jerusalem on the day of Pentecost with such effect that 3,000 persons were converted and baptized. With John he cured a lame man at the gate of the temple, and was brought before the sanhedrim and commanded to speak no more in the name of Jesus; but he courageously refused to obey this injunction. At his rebukes Ananias and his wife Sapphira, who had sold their goods and laid part of the price at the apostles' feet, pretending that it was the whole, were struck dead. After Philip had converted a great number in Samaria, Peter and John went down to them, and laid their hands on them that they might receive the Holy Ghost. (Acts viii. 14, 17.) Peter then returned to Jerusalem, preaching on the way in many Samaritan villages, and afterward went to Lydda, where he cured Æneas of the palsy. At Joppa he raised to life a Christian woman named Tabitha or Dorcas. While lodging here with one Simon, a tanner, he was taught by a vision that the gospel should be preached not only to the chosen people, but also to the gentiles, and instructed to accompany 3 men who had been sent to him by Cornelius, a centurion who dwelt at Cæsarea. Having baptized this man and his household, he returned to Jerusalem, where some of the brethren rebuked him for holding intercourse with the uncircumcised; but on hearing of his vision they held their peace and glorified God. Imprisoned by Herod (A. D. 44), he was released by an angel and went to Cæsarea. He next appears at a council of the apostles and elders at Jerusalem (A. D. 51), when he advocated the exemption of gentile converts from the ceremonial obligations of the Mosaic law; but St. Paul relates that he "withstood Peter to his face," because, after living freely with the gentiles at Antioch, he withdrew from them through fear of giving offence to the converted Jews. (Gal. ii. 11–14.) The remainder of his history rests upon tradition. Jerome, Origen, Eusebius, Chrysostom, and others relate that he became bishop of Antioch, where he passed several years. He appears also to have preached in Pontus, Galatia, Bithynia, Cappadocia, and the province of Asia. According to Eusebius, Jerome, and others, he was for the last 25 years of his life bishop of Rome; but if this is true, which many Protestant critics doubt, he did not remain all the time in that city. His first visit is supposed to have been made about A. D. 40, or 4 years before his imprisonment by Herod at Jerusalem. Returning to Rome after his release, he is said to have been banished by the emperor Claudius in 49, but he was soon permitted to reënter the metropolis, and suffered martyrdom there in the reign of Nero.—St. Peter is the author of two canonical epistles, the first of which, dated from Babylon, whereby some suppose is meant Rome, was probably written between 45 and 55. It is addressed chiefly to the converted Jews, and its purpose was to confirm them in their faith under persecution and to confute the errors of Simon and the Nicolaitans. The second epistle is likewise addressed to the Jews, and is supposed to have been written shortly before the apostle's death. Its authenticity has often been doubted, but that of the first epistle is generally unquestioned. They are both glowing and rapid in style, and as literary productions have elicited the warmest admiration.

PETER I. ALEXEIEVITCH, czar of Russia, known as Peter the Great, born in Moscow, June 10, 1672, died in St. Petersburg, Feb. 8, 1725. His father Alexei died in 1676, and was succeeded by Feodor, the heir apparent. Feodor died in 1682 without issue, naming Peter as his successor, to the exclusion of Ivan, the next heir, an imbecile youth. An insurrection followed, fomented by their sister Sophia, a young woman of great ambition and some talents. The difference was settled after much bloodshed by the joint coronation of Ivan and Peter (May, 1682), with Sophia as regent. For 7 years, she held the reins of government. Peter, when 17 years of age, married the daughter of one of his nobles, the boyar Feodor Abrahamovitch, contrary to the regent's wishes, and soon afterward emerged from the life of retirement and idleness to which Sophia's ambition had consigned him, and, assisted principally by two foreigners, the Swiss Lefort and the Scotchman Gordon, assumed the direction of affairs. He shut up his intriguing sister in a convent, where she ended her life in 1704, and sent her minister, Prince Gallitzin, into banishment. Ivan voluntarily withdrew, leaving Peter in effect sole sovereign, and died in 1696. Peter came upon the stage of action with a neglected education, an impetuous temper, and sensual habits. He at once began numerous reforms. He organized a new army, entering the ranks himself, and rising through every grade; and this example he required his nobles to follow. Finding Russia without ships, he laid the foundation of a navy by employing Dutch and Venetian shipwrights to build several small vessels on Lake Peipus. He learned practical seamanship by cruising on board Dutch and English ships at Archangel, the only seaport Russia then had, and sent young Russians to Venice, Leghorn, and Holland for the same purpose. Looking to a maritime policy, he besieged and took the Turkish city of Azof near the Black sea (1696), and in the same year divorced his wife on account of her opposing his plans. In order to improve his semi-barbarous subjects, he fostered communication with the western nations of Europe, at whose courts Russia was not then represented; and, sensible of his own deficiencies, he left his dominions for a temporary residence abroad (1697). This journey is an epoch in the history of his empire. He went first with a few attendants to live at Saardam, a famous ship building village of Holland, where, in disguise as a Dutch skipper, Pieter Timmerman by name, he led the life of a common shipwright. "He rose early, boiled his own pot, and received wages for his labor." He was then described as being "very tall and robust, quick and nimble of foot, rapid in all his actions, his face plump and round, fierce in his look, having brown eyebrows and curling brown hair, and swinging his arms in walking." To practical ship building and kindred trades he added various studies, as natural philosophy, astronomy, and geography, and attended the anatomical lectures of Ruysch at Amsterdam. From Holland he went to London (Jan. 1698), and took up his residence in Norfolk street. Here, says Macaulay: "His stately form, his intellectual forehead, his piercing black eyes, his Tartar nose and mouth, his gracious smile, his frown black with all the stormy rage and hate of a barbarian tyrant, and, above all, a strange nervous convulsion which sometimes transformed his countenance, during a few moments, into an object on which it was impossible to look without terror, the immense quantities of meat which he devoured, the pints of brandy which he swallowed, and which, it was said, he had carefully distilled with his own hands, the fool who jabbered at his feet, the monkey which grinned at the back of his chair, were, during some weeks, popular topics of conversation." He soon removed to Deptford, where he occupied the house of John Evelyn. In one of the streets a tavern is shown, still bearing the sign of the czar's head, where he smoked and drank beer and brandy. He returned to Holland in April in a yacht which King William had presented to him, taking along with him a number of men of science. He thence proceeded to Vienna to inspect the emperor's army, the best in Europe, and was preparing to visit Italy when the news of a rebellion at home caused his return after an absence of 17 months. The insurgents, whom Gordon, his general, had put down, he punished with savage cruelty. Mutiny having raised its head against him twice before, he doubtless thought summary vengeance necessary to the safety of his throne. As a further security he disbanded the strelitzes, a corps of soldiers who had constituted the body guard of the czars, and had always been a hot-bed of court intrigue, and formed new regiments on the German model. For revenue he introduced taxation, which included his subjects' beards, and the skirts of their Tartar coats. As the Russians did not choose to spare these appendages, they became a fruitful source of income. He regulated the press, caused valuable translations to be made and published, and established naval and other schools. He required his subjects to trade with other countries, which was formerly a capital crime. To the horror of the priests, he altered the calendar, making the year begin on Jan. 1 in place of Sept. 1 as before, and instituted the order of St. Andrew, the patron saint of Russia. After thus giving a new vigor to the interior life of his kingdom, he resolved to have a foreign policy also. To recover the provinces of Ingria and Carelia, which had formerly belonged to the Russian monarchy, he formed an alliance with Augustus II. of Poland and the king of Denmark against the young king of Sweden. The first fruit of the league was the disastrous battle of Narva. (See CHARLES XII.) But Peter with unbroken spirit applied himself vigorously to repair his losses, declaring that his enemies would teach him how at length to beat them. He melted down the church bells for cannon, and built as a barrier against Swedish invasion a fleet of small vessels on Lake Ladoga. In 1702 a Russian force defeated the Swedes and took Marienburg. By cautious manœuvring he succeeded in getting possession of the river Neva, at the mouth of which, among marshes, he laid the foundations of St. Petersburg (1703).

In 1704 he became master of the whole of Ingria, and appointed Prince Mentchikoff viceroy. When Augustus, intimidated by the Swedish monarch, abdicated the throne of Poland in favor of Stanislas Leszczynski, Peter entered Poland with an army, assembled a diet, and deposed Stanislas. But Charles XII. soon appearing, Peter found it necessary to retire. The royal Swede was on his march with 70,000 men to execute the magnificent project of wresting Russia from the czar. The rash expedition terminated at Pultowa, July 8, 1709. Peter celebrated a triumph at Moscow, and in the following year conquered the whole of Livonia and Carelia. Charles, who took refuge in Turkey, instigated Achmet II. against Peter. A war ensued, in which the czar was narrowly saved from destruction (1711) by the finesse of his mistress Catharine, afterward his wife and successor (see Catharine I.), and the sacrifice of Azof. He built defensive works in his capital; and by the construction of ships, dockyards, and wharfs, which gave employment to some 40,000 laborers, he laid a substantial basis for commerce. This commerce he inaugurated by making commercial regulations favoring St. Petersburg. In 1713 he removed the senate from Moscow to the new city, and in 1715 the summer and winter palaces were completed. In company with the empress Catharine he made a second tour of Europe in 1716, and was received at Paris with great splendor. He carried back a large quantity of books and works of art to adorn St. Petersburg. His son Alexei, the child of his first marriage, and heir to his throne, evincing a treasonable spirit, was tried and condemned to death (see Alexei); a few days afterward (July 7, 1718) he died in prison, leaving a suspicion of foul play. The protracted differences between Russia and Sweden were finally composed after the death of Charles XII., by the treaty of Nystad (1721), under which Sweden ceded to her rival Livonia, Esthonia, Ingria, a part of Carelia, the territory of Viborg, the isle of Oesel, and all the other islands in the Baltic from Courland to Viborg. For these concessions Russia agreed to surrender Finland, to pay $2,000,000, and to allow a free export of corn, to the annual value of 50,000 rubles, from the ports of Riga, Revel, and Arensberg. Peter now turned all his energies to the development of the industrial resources of his empire. He built canals and factories, established a uniformity of weights and measures, and paved the streets of Moscow and St. Petersburg. He framed codes, organized tribunals, and instituted hospitals. To polish the manners of his court, he ordered the young nobles to visit western Europe in company with their wives. In 1723 he founded at St. Petersburg the academy of sciences. His last war was against Persia, in which he gained the Caspian territories of Derbent, Bakoo, Ghilan, Mazanderan, and Astrabad (1722-'3). At last, being afflicted with a distressing and dangerous disease, he appointed the empress Catharine his successor, and caused her to be publicly crowned a few months before his death.

PETER of Blois, or Petrus Blesensis, an ecclesiastical writer of the 12th century, born in Blois, France, died in England in 1200. He studied at Paris and Bologna, and was afterward a pupil of John of Salisbury, bishop of Chartres. In 1167 he went to Sicily, where he became secretary to King William II. Falling into disgrace, he accepted an invitation from Henry II. to settle in England, was made archdeacon of Bath and chancellor of the diocese of Canterbury, visited Rome on ecclesiastical business during the pontificates of Alexander III. and Urban III., and in the latter part of his life received the archdeaconry of London. By command of the king he made a collection of his letters, 183 in number; beside which there are extant of his several sermons, treatises on doctrinal and ethical subjects, and a work on canon law and process lately discovered.

PETER THE HERMIT, the apostle of the first crusade, born of good family in the diocese of Amiens, France, about the middle of the 11th century, died in a monastery near Huy in 1115. After trying several pursuits in life without finding satisfaction in any of them, he became a hermit, and about 1093 undertook a pilgrimage to Jerusalem, where the oppressions which he witnessed and experienced determined him to arouse the people of Christendom to undertake a war for the liberation of the holy sepulchre from infidels. (See Crusades.) The first company of crusaders which set out for Palestine was led by Peter himself. A part of it afterward separated from the rest under the command of Walter the Penniless, but it was dispersed in a quarrel with the Hungarians. The others reached no further than Nice, where they were defeated by the Moslems. Peter had left them before this, and his name was associated with the succeeding expedition which resulted in the taking of Antioch. While the crusaders were besieged in this city, he deserted, but was captured by Tancred and brought back. On the conquest of Jerusalem he preached a sermon to the crusaders on the Mount of Olives. After this he returned to Europe and founded the abbey of Neufmontier, near Huy, where he passed the rest of his life.

PETERBOROUGH, a N. central co. of Canada West; area, 1,005 sq. m.; pop. in 1851, 15,237. Its surface is undulating, and contains numerous lakes, from which flow several rivers, the largest being the Otanabee. Several railroads diverge from Peterborough, the capital.

PETERBOROUGH, a city of England, in Northamptonshire, situated on the left bank of the Nene, 40 m. by railway N. E. from Northampton, and 76 m. N. by W. from London; pop. 8,672. The cathedral is a fine specimen of Norman and early English architecture. It was founded in 655 by Peada VI., king of Mercia, but was destroyed by the Danes, and has since been rebuilt and received many additions and repairs. It is built in the form of a cross, 476 feet long, with transepts 203 feet broad, ceiling 78 and tower 150 feet high. Catharine of Aragon, wife of Henry VIII., and Mary, queen of Scots, were both buried in Peterborough cathedral; but the remains of the latter were removed by James I. to Westminster abbey. Peterborough is the seat of a bishop, and the dean and chapter exercise a certain jurisdiction over the town. It returns two members to parliament.

PETERBOROUGH, Charles Mordaunt, earl of, a British soldier and man of letters, born in 1658, died in Lisbon, Oct. 25, 1735. His youth until his 17th year was passed in the frivolous and profligate amusements of the court, wearying of which he joined an expedition sent to chastise the Barbary corsairs of the Mediterranean. Having seen severe service at Tripoli and elsewhere, he returned to England, was married, and succeeded to his father's title of Viscount Mordaunt. In 1678–'9 he again served against the Algerines, and upon his return to England took his seat in the house of lords as an opponent of the court. Subsequently he showed a strong sympathy for Lord Russell and Algernon Sidney, the latter of whom, in spite of the menaces of Jeffrey, he supported to the last and accompanied to the scaffold. His pecuniary circumstances becoming embarrassed in consequence of a reckless generosity, and all honorable employment being cut off at home, he repaired in 1686 to Holland, whence he returned to England with the prince of Orange. In April, 1689, he was created first commissioner of the treasury and earl of Monmouth, but retired from office in a few months with no great credit for political integrity. After serving in the campaign of 1691 on the continent, he lived for several years on his estates; but his restless ambition and vanity, which the king's refusal to recall him to power only inflamed, prompted him in 1696 to engage in the Fenwick plot, and he was for several months a prisoner in the tower, where "his only solace was to contrive wild and romantic schemes for extricating himself from his difficulties and avenging himself on his enemies." Released by the leniency of William, and finding himself an object of detestation to both whigs and tories, he again went into retirement, and in 1697 succeeded to the title of earl of Peterborough, inherited from his uncle, Henry Mordaunt, and which enabled him to dispense with the tarnished name of Monmouth. At this time he was reduced to such poverty that he talked of living like a farmer and putting his countess in the dairy to churn and make cheeses. The accession of Queen Anne opened the path of preferment to him, and by paying court to the duchess of Marlborough he procured the appointment of general-in-chief of the forces sent in 1705 to assist the cause of the archduke Charles of Austria, claimant of the crown of Spain. With an army of 7,000 undisciplined troops, principally Dutch and English, he captured Barcelona, having first carried by assault the almost impregnable citadel of Montjouich, which commanded the city, and, in the face of a vastly superior force having every advantage of position, commenced a campaign against the Spaniards, the narrative of which seems more like a chapter of romance than sober history. He quickly overran Catalonia, Aragon, and Valencia, and parts of Murcia and Castile, outwitting and alarming his enemies by the rapidity, secrecy, and mystery of his movements, defeating thousands of men with a mere handful, and not scrupling at any artifice which would insure success or increase his numbers or prestige. The advance in April, 1706, of an army of 20,000 men under Philip V. toward Barcelona, checked the triumphant career of Peterborough, and he hastened back to the city, into which he threw a portion of his forces, while the remainder occupied the heights surrounding the enemy's camp and cut off their supplies. After an obstinate resistance the Barcelonese were relieved by the arrival of a British fleet with supplies and reënforcements, and the besieging force retreated with precipitation, closely followed by Peterborough. Had the advice of the latter been followed at this juncture, and a rapid march made upon Madrid, the archduke might have been established upon the throne of Spain. Peterborough's manners, however, were not such as to conciliate the archduke or his fellow generals, who envied him his military successes and hated him for his arrogance and presumption. Dissensions subsequently arose among the allied generals, and Peterborough, finding his counsels disregarded, quitted Spain in disgust, and in 1707 returned to England, where he experienced a flattering reception, and was thanked by the house of lords for his "wonderful and amazing success." He was subsequently employed on embassies to Vienna and other continental courts, and, as in his Spanish campaign, moved so rapidly from place to place that he used to say that he had seen more postillions and princes than any other man in Europe. His ambition and vanity, joined with undoubted talents, made him in many respects an unsafe person to intrust with diplomatic duties, and he frequently exceeded his authority or gratified his restless desire for display by engaging in mischievous intrigues. Hatred of Marlborough induced him during the last years of Queen Anne's reign to side with the tories; and upon the accession of George I. and a whig administration, he returned to his country seat, and thenceforth ceased to figure in any important public capacity. Throughout his life he was the intimate friend of Dryden, Swift, Pope, Gay, and other eminent men of letters, and had a considerable reputation himself as an elegant writer. He is said to have composed his own memoirs, which after his death were destroyed by his countess, the celebrated singer Anastasia Robinson, with whom he contracted a second marriage in the last year of his life. His eccentricity, impetuosity, vanity, and romantic courage are sufficiently illustrated by the history of his public career. His military genius, brilliant as it was, was better adapted to partisan warfare than to any other kind, and his successes in Spain have been called "happy temerities." Macaulay calls him "the most extraordinary character of that age, the king of Sweden not excepted; . . . . a polite, learned, and amorous Charles the Twelfth;" a comparison suggested by Swift, who in his lines "To the Earl of Peterborough" says he was

> Ne'er to be matched in modern reading
> But by his namesake, Charles of Sweden.

In private life he was generous to profusion, passionate and unreasonable, the slave of temporary whims, an atheist in religious opinion, and almost to the close of his life a confirmed voluptuary. His friends liked him in spite of his faults. Swift confessed he "loved the hang-dog dearly," and he was even admired by Johnson. Burnet says he was "a man of much heat, many notions, full of discourse, brave and generous, with little true judgment, and no virtue." In person he was tall and graceful, but so attenuated that Swift compared him to a living skeleton. A "Memoir of Charles Mordaunt, Earl of Peterborough and Monmouth, with Selections from his Correspondence," by Eliot Warburton (2 vols., 1853), has been published posthumously.

PETERMANN, August Heinrich, a German geographer, born in Bleicherode, near Nordhausen, in Prussian Saxony, April 18, 1822. He was designed by his family for the church, but his preference for the study of geography led him to enter the academy which Berghaus had established at Potsdam. With Berghaus he lived 6 years, acting as his private secretary and librarian, and there made the acquaintance of many scientific men, including Humboldt, for whom he prepared in 1841 the map of central Asia. In 1845 he went to Edinburgh to aid A. K. Johnston in the preparation of the "Physical Atlas;" and in 1847 proceeded to London, where he became a member of the royal geographical society, wrote for the "Athenæum" accounts of the progress of geography, and in conjunction with the Rev. Thomas Milner prepared an "Atlas of Physical Geography." To him is due in great measure the aid which Barth, Overweg, and Vogel received from the English government in their African explorations, and he wrote an "Account of the Expedition to Central Africa." His hypotheses in regard to arctic geography have been supported by the alleged discovery of a polar sea made by Dr. Kane. In 1854 the duke of Saxe-Coburg invited him to occupy the chair of geography at the university of Gotha, and the following year he received the degree of Ph. D. from the university of Göttingen. At the same time he was employed to superintend the geographical establishment of Justus Perthes at Gotha, the largest in the world. From this place he publishes a monthly journal under the title of *Mittheilungen aus Justus Perthes, geographischer Anstalt* ("Communications from Justus Perthes' Geographical Establishment"), which embraces a view of all modern discoveries, with maps and charts.

PETERS, or Peeters, Bonaventura, a Flemish painter, born in Antwerp in 1614, died, according to most authors, in 1652, but according to Valkema in 1671. He was especially distinguished as a marine painter, depicting with great power and truth storms and wrecks. His best works are now scarce.

PETERS, or Peter, Hugh, an English dissenting clergyman and politician, born in Fowey, Cornwall, in 1599, executed in London, Oct. 16, 1660. He was graduated M.A. at Trinity college, Cambridge, in 1622, and preached for some time with great success at the church of St. Sepulchre in London; but having been committed to prison by Archbishop Laud for nonconformity, he removed, upon obtaining his release, to Rotterdam. After preaching to an Independent congregation there for several years, he embarked for New England, and arrived there in Oct. 1635. On Dec. 21, 1636, he became pastor of the church in Salem, succeeding Roger Williams, whose doctrines he disclaimed and whose adherents he excommunicated. During his residence in New England, he took an active part in mercantile and civil affairs; he suggested coasting and foreign voyages and the plan of the fisheries, and aided in reforming the town police. In March, 1638, he was appointed by the general court to assist in collecting and revising the colonial laws. In 1641 he was sent to England to procure an alteration in the laws of excise and trade; and it was probably owing to the influence of himself and his associates that an act of parliament was passed in 1643, relieving all commodities carried between England and New England from the payment of "any custom, subsidy, taxation, imposition, or other duty," till the further order of the house of commons. In England he joined the parliamentary party, became a preacher in the army, and in 1649 accompanied it to Ireland, holding, it is said, a colonel's commission. During the war he also had interviews with Charles I. in regard to his "New England business," in which, says Peters, "he used me civilly, and I offered my poor thoughts three times for his safety." In 1651 he was appointed by parliament one of the commissioners to amend the laws, an office for which he was eminently unqualified; and in 1654 he was made one of the "tryers" of ministers. In 1658 he preached for some time to the English garrison in Dunkirk. Accompanying Monk in 1660 on his march from Scotland to London, he preached before him on a fast day, and, it is said, "troubled the general with a long fast sermon; and at night too he supererogated, and prayed a long prayer in the general's quarters." After the restoration Peters was committed to the tower and indicted for high treason as having been concerned in the death of the king. It was also alleged that he was one of the masked persons who stood upon the scaffold when Charles was beheaded. During his imprisonment he wrote several letters of advice to his daughter, which were subsequently published under the title of "A Dying Father's Last Legacy to an Only Child." His other published works consist of sermons and political treatises. Though not a man of learning, he possessed no mean intellectual powers, and his preaching was rendered very popular among the multitude by the use of coarse but striking images. His private character has been the subject of much discussion both in England and America. He was charged by his enemies with gross immorality, and the most bitter epithets were applied to him by Bishops Burnet and Kennett, Dr. Barwick, Dr. Grey, and others; but of late years he has been estimated more favorably. According to Dr. Palfrey, his name should be written Peter.

PETERS, John Charles, M.D., an American physician, born in New York, July 6, 1819. At the age of 18 he commenced the study of medicine according to the system of Hahnemann, and in 1842 visited Europe, where, in the schools of Leipsic, Berlin, and Vienna, he studied homœopathy under its most eminent teachers, and received the instructions of the chief professors of pathological anatomy, pathological chemistry, materia medica, and the cognate sciences. Commencing practice in New York as a homœopathist, he gradually deviated in several essential particulars from the views entertained by physicians of that school, and is now understood to be in favor of a compromise between the homœopathic and allopathic schools of medicine, both in theory and practice. On this subject he holds that the homœopathic law, *similia similibus curantur*, is not universally true, but is a complement of the general law of medical treatment, *alterantia alterantibus curantur*; that similar things differ as well as resemble, and as a medicine which acts similarly to a disease necessarily acts somewhat differently from it, it follows that homœopathic remedies exert an alterative action, and should be given in sufficient doses to bring about this effect; that as similarity may be considered a lesser or the least *degree of difference*, and antagonism a greater or the *greatest* degree of difference, the apparently antagonistic laws *similia similibus curantur* and *contraria contrariis curantur* are not only not diametrically opposed to, but are the complements of each other; hence homœopathy and antipathy are not in reality opposing systems, but are parts of the great law of specific alterative or specific allopathic treatment. Among the suggestions made by him which have been adopted in medical practice are the employment of alcohol in the treatment of consumption; the use of phosphates in medicine; the curative treatment of Bright's disease of the kidneys with corrosive sublimate; and the use of bromine and bromide of potash as specific remedies in true membranous croup. He has devoted himself especially to the study of the materia medica and the theory and practice of medicine, and has endeavored to incorporate in homœopathy such improvements in medical practice as auscultation and percussion, microscopy, the use of the ophthalmoscope, pathological anatomy and chemistry, &c. His medical publications consist of a "Treatise on Diseases of the Head" (8vo., New York, 1853); "Treatise on Diseases of Females" (8vo., 1854); and "Treatise on Diseases of the Eyes" (8vo., 1855). In conjunction with Dr. Wetherspoon he translated "Rokitansky's Pathological Anatomy" (8vo., 1849); and in conjunction with Dr. F. G. Snelling and others he has published a "Materia Medica" (8vo., 1856–'60). He is now engaged upon a "Treatise on the Principles and Practice of Medicine," published in numbers, and which is to form 2 vols. 8vo. He was also editor of the "North American Journal of Homœopathy" from 1856 to 1861. He was one of the founders of the New York pathological society, and in 1859 was elected president of the American college of medical sciences, and professor of materia medica and therapeutics in the same institution. This college, however, has not yet been opened for students.

PETERS, Richard, an American jurist, born near Philadelphia, Aug. 22, 1744, died Aug. 21, 1828. He was educated in Philadelphia, and embraced the profession of law. At the breaking out of the revolution he became captain of a company of volunteers, and in June, 1776, was appointed by congress secretary of the board of war. On resigning this post in 1781 he was elected a member of congress, and after the organization of the government he was offered by Washington the comptrollership of the treasury of the United States. This he declined, but accepted the office of judge of the U. S. district court for Pennsylvania, a position which he retained for the rest of his life. The admiralty law of the United States may be said to owe to him its foundation. He was also eminent as an agriculturist, being president of the Philadelphia agricultural society; and through his instrumentality the use of gypsum in agriculture and the cultivation of clover were introduced in the United States.

PETERS, Samuel, an American clergyman and historian, born in Hebron, Conn., Dec. 12, 1735, died in New York, April 19, 1826. He was graduated at Yale college in 1757, became in 1760 a clergyman of the church of England, and in 1762 took charge of the churches of Hartford and Hebron. Being a tory, he was forced in 1774 to flee to England, where he revenged himself on the Puritans by publishing in 1781 "A General History of Connecticut," which has been called the "most unscrupulous and malicious of lying narratives." In 1794 he was chosen bishop of Vermont by a convention of that diocese, but was never consecrated to the office. In 1805 he returned to America, and in 1807 published in New York a "History of the Rev. Hugh Peters," his great-uncle. In 1817 he made a journey to the falls of St. Anthony, claiming a large tract of land in that region. He is the "Parson Peter" of Trumbull's "McFingal."

PETERS, Samuel Jarvis, an American merchant, born in York, now Toronto, Canada, July 30, 1801, died in New Orleans, Aug. 11, 1855. He was a descendant of Hugh Peters. After passing some time in a French counting room in New York, he removed to New Orleans in 1821, became clerk in a wholesale grocery house, and in 1823 began business for himself as a wholesale grocer in partnership with a Mr. Millard. Of this firm, which was in time one of the most important in the trade, Mr. Peters continued a member as long as he lived. In 1829 he was elected to the city council of New Orleans, and after the division of the city into municipalities was chosen to a similar office in the second municipality, and made chairman of the finance committee. In the latter capacity he was identified with numerous improvements. He was one of the originators of the Pontchartrain railroad and its first president, of the chamber of commerce, of which he was president until his death, and of the city bank, of which he was also president for 20 years. He was afterward president of the state bank of Louisiana, was appointed collector of the port in 1849, and was instrumental in introducing the common school system into New Orleans. In connection with the schools he founded a public lyceum and library, which are now flourishing.

PETER'S PENCE, an annual tribute of one penny formerly paid to the pope on the festival of St. Peter. In England, where every family possessed of 30 pennyworth of property of any kind was considered liable to this tribute, it was continued from Saxon times to the reign of Henry VIII. The tribute was collected by the bishops. The term is also applied to any general voluntary collection made for the pope, such as that in 1860; on Jan. 1, 1861, the amount received at Rome from this collection had exceeded $2,000,000.

PETERSBURG, a city and port of entry of Dinwiddie co., Va., on the S. bank of the Appomattox river, 12 m. above its entrance into the James at City Point; pop. in 1850, 14,010; in 1860, 18,275. It is the third city in the state in population, and is favorably situated for business. The river is navigable to this place, which is at the head of tide water, for vessels of 200 tons; larger vessels load and discharge at Port Walthall, 6 m. below, on the N. bank of the river, and the largest at City Point. Immediately above the city the falls afford extensive water power. Above the falls the Appomattox is made navigable for bateaux to Farmville, 107 m. Petersburg is connected by railroad with City Point, Richmond, Norfolk, Lynchburg, and Weldon on the border of North Carolina. There is a continuous line of railroad communication from Petersburg to Mobile, and also to Memphis, Tenn. The city is lighted with gas, and abundantly supplied with water from a reservoir. It is well built and naturally drained, the ground descending gradually from the heights on the southern outskirts down to the river. The principal public buildings are the custom house and post office, court house, mechanics' hall, Phœnix hall, and a library of 5,000 volumes. There are 4 banks, 4 savings institutions, 3 daily and 2 weekly newspapers, and 14 churches, viz.: 2 Baptist, 2 Episcopalian, 3 Methodist, 2 Presbyterian, 1 Roman Catholic, and 4 for colored people. There are 50 productive or manufacturing establishments, with an aggregate capital of $1,104,000, consuming annually $2,076,000 worth of raw material, and employing 2,142 males and 961 females; value of products, $3,528,677. The sales of cotton during the year ending Sept. 30, 1858, amounted to 17,028 bales, 1859, 28,069; 1860, 30,000; 1861, 35,000. The receipts of tobacco in 1859 were 26,000,000 lbs.; quantity manufactured, 12,000,000 lbs., in 20 factories. The tonnage of the port in 1859 was 2,562 tons.—Petersburg was incorporated in 1748. It was twice occupied by the British under Gen. Phillips during the revolutionary war. The Petersburg volunteers served with distinction on the Canada frontier during the last war with England, and it was Mr. Madison, then president, who, referring to their gallantry, first styled Petersburg "the cockade of the South."

PETERSEN, Frederik Christian, a Danish philologist and archæologist, born in Autserskon in Seeland, Dec. 9, 1786. He was educated at the university of Copenhagen, and in 1826 became a member of the Danish academy of science, and in 1842 ordinary professor of philology in Copenhagen. Beside contributing to scientific journals many valuable articles, he has written an "Introduction to the Study of Archæology" (Copenhagen, 1825), and a "Handbook of Greek Literary History" (Copenhagen, 1826).

PETERWARDEIN (Hun. *Pétervárad*), a fortress and town of Austria, in the Slavonian Military Frontier, on the right bank of the Danube, 44 m. N. W. from Belgrade; civil pop. about 4,000, garrison 3,000. The fortress is built on a lofty escarped rock overhanging a sharp promontory formed by a bend of the river, opposite the town and steamboat station of Neusatz in the Hungarian county of Bács, contains extensive barracks and arsenals for a large force, and presents to the water and land side a formidable face of walls, port holes, and bastions. The place is of high strategic importance, and the Romans are believed to have had there one of their Pannonian military colonies, called Acumincum. The modern name is traced to Peter the Hermit, who mustered there his motley host of crusaders. Prince Eugene won there a great victory over the Turks in 1716, which completed the deliverance of Hungary from the Moslem yoke. During the war of 1848-'9 Peterwardein was continually in the hands of the Hungarians, capitulating only after the surrender of Görgey and of the fortress of Arad.

PETHERICK, John, a British traveller in Africa. In 1845 he went to Egypt, entered the service of Mehemet Ali as mining engineer, and was sent by the pasha to Arabia Petræa to seek for coal. After extensive unsuccessful researches he returned to Cairo, and in Jan. 1847, was ordered to proceed to Kordofan and report upon some iron mines. He spent several years in the region of the upper Nile in the service of the Egyptian government; but on the death of Mehemet Ali he resigned his employment and established himself as a merchant at Khartoum, where he was made British consul. In 1853, and repeatedly again in subsequent years, he ascended the White Nile, and penetrated beyond all former travellers into the interior of Africa. In 1859 he returned to England, and after a residence there of two years, during which he published a highly interesting account of his explorations, entitled "Egypt, the Soudan, and Central Africa, with Explorations from Khartoum on the White Nile to the Regions of the Equator" (London and Edinburgh, 1861), he set out in April, 1861, from England for another expedition up the Nile, expecting to meet Capt. Speke and his companions in their advance northerly from the lake region of E. Africa.

PÉTIGNY, François Jules Filleul de, a French historian, born in Paris, March 14, 1801. He studied at the school of charts, was appointed in 1826 counsellor to the prefecture of Loir-et-Cher, and after the revolution of 1830, by which he lost his office, devoted himself to literary pursuits, and especially to researches in French history. His first work was an essay "On the History, Laws, and Institutions of the Merovingian Epoch" (3 vols. 8vo., Paris, 1844), for which the institute awarded him the Gobert prize of 9,000 francs; and in 1849 he received a gold medal from the same learned body for his "Archæological History of the Vendômois." He has also published "Observations on Recruiting the Army" (1830), and various historical and antiquarian papers in the *Bibliothèque de l'école des chartes*, the *Revue numismatique*, and the *Mémoires* of the society of sciences and letters of the city of Blois. He was chosen a member of the academy of inscriptions and belles-lettres in Dec. 1850.

PETIGRU, James Louis, an American lawyer, of mixed Irish and Huguenot descent, born in Abbeville district, S. C., about 1789. He was graduated at the South Carolina college in 1809, and a few years later was admitted to the bar, commencing practice as a country lawyer. Having attained great professional eminence in the rural districts, he removed to Charleston, where he rapidly rose to distinction. In 1822 he succeeded Robert Y. Hayne as attorney-general of the state, which office he held for 8 years. During the nullification troubles of 1830-'32 he took sides against the doctrine of the state veto, and became one of the leaders of the "union and state rights" party, which, while adopting to their fullest extent the opinions of the nullifiers on the subject of a protective tariff, and those of Calhoun, McDuffie, Hayne, and others respecting state rights, nevertheless joined issue with the nullifiers on the practicability of applying the state veto to measures adopted by the federal congress. During the controversy, which several times threatened to end in civil war, he showed himself an earnest worker and a vigorous and eloquent speaker; and upon the defeat of his party, he became in his political capacity an object of much popular dislike, his views being considered antagonistic to the recognition of the sovereignty of the state, and identical with measures of federal usurpation. His talents and virtues, and his unquestioned ability as an advocate, nevertheless secured him the respect of the community in which he lived, and he continued to maintain his position as a leader at the bar with scarcely a rival. Subsequently he held for a brief period the office of district attorney of the United States, at a time when such a position subjected him to public odium. He has also served in the state legislature, and is now (1861) a commissioner for codifying the laws and statutes of South Carolina. Although opposed to the secession movement of 1860-'61, he has followed the fortunes of South Carolina; and notwithstanding his views are shared by a very inconsiderable portion of the people of the state, public respect for his character is undiminished.

PÉTION (or Péthion) DE VILLENEUVE, Jérôme, a French revolutionist, born in Chartres in 1753, died by his own hand in 1793. He was a lawyer by profession, and in 1789 was elected by his native town deputy to the states-general. His fine figure and countenance, sonorous voice, fluent speech, fervor, and integrity secured him considerable influence over his colleagues and the people. He was styled *le vertueux Péthion*. He was a bitter enemy of the court and of Mirabeau, and was one of the 3 commissioners who after the flight to Varennes, June, 1791, were sent by the constituent assembly to bring the royal family back to Paris, when he treated his illustrious prisoners with unpardonable roughness, and wished the king to be at once placed on trial. Being elected mayor of Paris in preference to Lafayette, he secretly assisted in the popular manifestation of June 20, 1792, and was consequently suspended from his functions by the departmental directory, but was restored by order of the assembly, which had become alarmed by the popular cry of "Pétion or death!" He participated in the insurrection of Aug. 10, when he caused himself to be kept under guard by his own friends in order to be excused from any active proceedings to quell the troubles; neither did he interfere to stop the dreadful massacres of September. In 1792 he was elected a deputy to the convention by the department of Eure-et-Loir, and nominated the first president of that assembly. He now leaned toward a milder policy, sided with the Girondists, and lost his popularity. He had insisted upon Louis XVI. being tried, and voted for his death, but on condition that an appeal might be made to the people. This was a crime in the eyes of the revolutionists. He was proscribed in conjunction with the Girondists, escaped from Paris, and repaired first to Caen, and then to the vicinity of Bordeaux, where he wandered for some months and finally killed himself. His body was found half devoured by wolves. The works of Pétion were published in Paris in 1793 (4 vols. 8vo.); they consist of speeches and political tracts, of merely temporary interest.

PÉTION (Anne Alexandre Sabès), first president of the republic of Hayti, born in Port-au-Prince, April 2, 1770, died March 29, 1818. His father was Pascal Sabès, a wealthy colonist, and his mother a free mulatto. He studied at the military academy of Paris, served in the French and afterward in the Haytian army, and when the revolution broke out in his native island rendered valuable services to Toussaint and Dessalines as an engineer, and was rapidly advanced. He did much to protect the colonists in that time of terror, and his mild disposition and engaging manners recommended him to all classes. When Toussaint began his proscription of the whites and mulattoes, Pétion took up arms to resist him, and maintained the conflict, with very unequal forces, until compelled to seek refuge in France. He returned from exile as a colonel in the army sent under Gen. Leclerc to subject Hayti anew to her former masters; but the retaliatory cruelties committed by that commander, and the conduct of the French toward Toussaint and Rigaud, impelled him to quit the army; and placing himself under the orders of Dessalines, they once more proclaimed the independence of Hayti (1804). Having succeeded Gen. Clervaux in the government of Port-au-Prince and the command of the mulattoes, Pétion held that post at the time of the assassination of the negro emperor (Oct. 1806). In the dissolution of the government which ensued, the mulattoes rallied round Pétion, whom they preferred, as one of their own caste, to Christophe, the leader of the blacks. Pétion accordingly was elected, June 27, 1807, president of the southern and western parts of the island; an office which was afterward conferred upon him in perpetuity, with the right of nominating his successor. Christophe believing himself entitled to undivided authority, the rivals took up arms, and for several years carried on a war without decisive results, but in which the advantage seems to have been on the side of Christophe, who on one occasion defeated Pétion in a pitched battle, and pursued him to Port-au-Prince. At length the chieftains agreed, without entering into any formal treaty, to suspend hostilities, and leave each other undisturbed. A strip of waste country, 10 miles wide, was made the neutral boundary between their territories. Pétion now applied himself zealously to the improvement of his subjects. With absolute power he preserved the utmost republican simplicity. Property was equitably divided, without respect to distinctions of color; great attention was paid to public instruction, and the general forms of administration were copied from French models. But an insurmountable barrier was opposed to his exertions by the character of the recently emancipated blacks who formed the majority of his subjects. The finances of the country fell into irretrievable disorder; onerous imposts upon commerce were resorted to, and the government was compelled to debase the coinage. The army was a mere rabble, unpaid, undisciplined, and ill fed. All this wretchedness and confusion, which he saw no means of remedying, had at length such an effect on the benevolent, though somewhat over-cautious and irresolute Pétion, that he fell into a state of hypochondria, fancying that he was in danger of assassination. Finally, he refused all medicines and nourishment, and, after designating Gen. Boyer as his successor, died of mere inanition and despondency, amid the universal and profound grief of the people. His body was conveyed to Paris, and now rests in the cemetery of Père la Chaise.

PÉTIS DE LA CROIX, François, a French orientalist, born in Paris in 1653, died Dec. 4, 1713. He was the son of the king's interpreter for oriental languages, and was educated for the same employment, passing several years at Aleppo, Ispahan, and Constantinople. In 1682 he went to Morocco as secretary to the French ambassador, and was afterward employed as secretary-interpreter in the expeditions against Algiers, the negotiations with Tunis and Tripoli, and many other transactions between the French government and the East. In 1692 he was appointed professor of Arabic in the royal college of France, and in 1695 succeeded his father as oriental interpreter, an office in which he himself was succeeded after his death by his son Alexandre Louis Marie. Beside Arabic, Persian, and Turkish, he is said to have understood the Mogul, Armenian, and Ethiopian languages. He spoke and wrote Arabic with remarkable fluency and elegance, and during his residence at Aleppo translated into that tongue an account of the campaign of Louis XIV. in the Netherlands, which was published in 1671. He translated the "Turkish Tales" from Sheikh Zadeh (12mo., Paris, 1707), and from the Persian the "Thousand and One Days" (5 vols. 12mo., 1710–'12), and Sheref-ed-deen Ali Yesdi's "History of Timur" (4 vols., 1722).

PETIT-THOUARS. See Du Petit-Thouars.

PETITOT, Claude Bernard, a French author, born in Dijon in 1772, died in Paris, April

6, 1825. He filled various public offices, devoted his leisure hours to literature, wrote 3 worthless tragedies which he himself suppressed so far as he was able, translated those of Alfieri and the novels of Cervantes, edited Molière and La Harpe, and published the *Répertoire du théâtre français* (23 vols. 8vo., Paris, 1803–'4, and 25 vols. 8vo., 1817–'18), and a collection of *Mémoires relatifs à l'histoire de France* (56 vols. 8vo., Paris, 1819–'34), to which he added biographical and historical essays of some interest.

PETITOT, Jean, a Swiss painter on enamel, born in Geneva in 1607, died at Vevey in 1691. His father was a sculptor and architect; he himself first followed the trade of a jeweller, and, in concert with his master Bordier, gave particular attention to improving the fabrication of enamel. After visiting Italy they removed to England, where, under the direction of Mayerne, the head physician of King Charles I. and a learned chemist, they invented processes for preparing colors which enabled them to excel the best works of Venice and Limoges. Charles I. treated Petitot with marked favor, gave him lodgings in Whitehall, knighted him, and ordered him to make copies of Vandyke's pictures on enamel. He accompanied Charles II. in his exile to France, where the liberality of Louis XIV. induced him to settle. He now copied some of Mignard and Lebrun's best compositions, and painted portraits of many of the celebrated characters of the French court. His masterpiece in this line was the portrait of the countess of Southampton. He accumulated a large fortune. On the revocation of the edict of Nantes in 1685, he was imprisoned as a Calvinist, and released only when lengthened confinement had endangered his life. He now retired to Geneva, where he passed the rest of his days.

PETÖFI, Sándor, a Hungarian poet, born in the district of Little Cumania, Jan. 1, 1823, disappeared on the battle field of Schässburg in Transylvania, July 31, 1849. He was the son of an innkeeper and butcher, and was sent successively to the schools of Aszód, Szent Lőrincz, and Schemnitz; but being wayward, obstinate, and a poetical dreamer from his infancy, he was expelled or deserted from the last named school, and served for some time as scene shifter in a theatre at Pesth, until he was discovered by his father and taken home. He was treated harshly by his father, but tenderly by his mother, and after some 20 months was again sent to school, this time to Oedenburg. Scarcely arrived, he enlisted as a volunteer in an Austrian regiment, with which he was sent to Croatia, and subsequently to Styria; but was soon dismissed, and went to the college of Pápa. He left Pápa in 1842, after having seen his first printed song in Bajza's *Athenæum*, and for some time led the life of a poor strolling player, wandering generally alone through the plains of Hungary, composing short popular songs, and subsisting by the hospitality of the peasantry. From Debreczin, where he spent the winter of 1842–'3, and acted without success in the plays of Shakespeare, he repaired, penniless and on foot, to Pesth, bringing with him a collection of songs, some of which had already appeared in the *Athenæum*. He earned some money by translating one of James's novels and another of Bernard, contributed to the *Életképek* ("Pictures of Life"), and assisted Vahot in editing the *Divatlap* ("Journal of Fashion"). His fame as a writer of popular songs rose from day to day, but he met with little success in other branches of literary or artistic labor, a novel entitled *A hóhér kötele* ("The Hangman's Rope"), and a drama, *Tigris és hiéna* ("Tiger and Hyena"), as well as a last attempt to figure on the stage, proving decided failures. Two popular epic sketches, *A helység kalapácsa* ("The Hammer of the Place"), and *János vitéz* ("Warrior John"), were favorably received. On a tour through the northern parts of Hungary he received marks of enthusiastic admiration. During a subsequent tour along the upper Theiss he married a young girl, a passionate admirer of his poetry. When, at the general convention of the opposition preceding the opening of the diet of 1847, he recited his poem *Dalaim* ("My Songs"), the members rose and embraced him. The events of February and March, 1848, opened for him the career of revolutionary activity. Scarcely had the news of the occurrences at Vienna of March 13 reached Pesth, when Petöfi, accompanied by Jókai, Vasváry, and Bulyovszky, on the morning of the 15th assembled the students of the Hungarian metropolis, and, repairing with a crowd of people to one of the principal printing establishments, compelled the workmen to print without permission from the censor the "Twelve Demands of the Hungarian Nation," and a stirring revolutionary song of the young poet, entitled *Talpra magyar!* ("Hungarians, arise!"). Both were distributed and read before numberless multitudes, amid the general acclamations of the people. The municipality gave its adhesion, a committee of public safety was formed, and the royal lieutenancy of Buda was compelled to yield. Petöfi now devoted his poetry exclusively to quickening the revolutionary movement. Appeals, odes, and battle songs followed each other; and finally he girded on the sword himself, and accompanying Bem on his Transylvanian campaign, with only a short interruption, continued as his aide-de-camp until the disastrous day of Schässburg, where Petöfi was last seen among the scattered remnants of the army, pursued by Cossacks. His dead body was not found. There is little doubt that he was killed by the pursuers; but to this day the popular belief in Hungary is that the great minstrel of the revolution still lives in foreign parts or in one of the dungeons of Austria, soon to reappear. Stories of his alleged reappearance at various places are current, and many a patriotic pen is active in defending the one or the other side of the question, though the widow of the poet has long been remarried. A lively controversy on the subject took place, at the beginning of 1861, in the columns of the Pesth *Vasárnapi ujság* ("Sunday News"), edited by Pákh, an early friend of Petőfi. Among the translators of his songs in German are Szarvady and Hartmann (jointly) and Vasfi (*nom de plume* of Dr. M. Eisler, now of New York). A collection in French, interwoven with interesting sketches of the poet and his country, was published by Chassin under the title of *Le poëte de la révolution Hongroise Alexandre Petœfi* (Brussels and Paris, 1860).

PETRA, an ancient city of Arabia Petræa, about half way between the Dead sea and the head of the Ælanitic gulf. The ancient geographers describe it as situated in a narrow valley, surrounded by precipitous hills, beyond which, especially in the direction of Judæa, were deserts. On the W. side rises Mt. Hor. The entrance to the ruins of this long lost city, first discovered by Burckhardt in 1812, is generally made through the *sik* or ravine of Wady Musa, a winding street of a mile in length, lined on both sides with tombs hewn out of the rocky cliff. At the opening of this avenue is the Khuzneh, the supposed great temple of Petra, but bearing no inscription. It is in the Corinthian style, and is called by the Arabs *El Khuzneh* (the treasure), from a tradition that one of the Pharaohs enclosed a vast amount of money and jewels in an urn surmounting the façade. Beside this and the numerous tombs, which form the most remarkable and interesting remains of Petra, the most striking edifices are the Deir, a huge temple hewn in the rock; the theatre, excavated from the rock, with an arena 120 feet in diameter, and capable of accommodating from 3,000 to 4,000 spectators; and the acropolis. The remains of the city in the plain are now a heap of rubbish.—Petra is supposed to be the same as Selah, referred to twice in the Old Testament (2 Kings xiv. 7, and Isaiah xvi. 1), both names signifying rock. It was a city of Edom, but was taken several centuries B. C. by the Nabathæans, an Arab tribe, who made it their chief city. It successfully resisted the attacks of the Seleucidæ, and Strabo mentions that in his time it was still governed by a native prince. It was then a large and important town, owing its prosperity to the trade of caravans, for which it was a halting place. In the time of Trajan it was under the dominion of the Persians, from whom it was captured by his lieutenant A. Cornelius Palma. It is spoken of by Pliny, Josephus, Eusebius, and Jerome; and in the *Notitiæ Ecclesiasticæ* of the 6th century it is mentioned as an episcopal see. After its capture by the Mohammedans, it disappeared altogether from history, and remained unvisited and forgotten, at least after the beginning of the 13th century, until the discovery of Burckhardt. It was visited by Irby and Mangles, Banks, and Leigh in 1818, afterward by Laborde and Linant, and by Robinson, Stephens, and others.—See *Voyage dans l'Arabie Pétrée*, by Laborde and Linant (Paris, 1830), of which a condensed English translation was published in London in 1845.

PETRARCH (Francesco Petrarca), an Italian poet, born in Arezzo, July 20, 1304, died in Arqua, July 18, 1374. He was the son of Pietro or Petracco (an idiomatic form of Pietro), and his baptismal name of Francesco di Petracco he afterward changed to that by which he is now known. His father, who was a notary of Florence, had taken part in the contests between the Guelphs and Ghibellines which were then desolating Italy, and along with Dante and other members of the Bianchi party was driven from his native city. The family did not remain long in Arezzo, where it settled at first, and when Petrarch was 7 months old his mother, not being included in the sentence of banishment passed on her husband, removed to Ancisa in the neighborhood of Florence. There he remained 7 years, until he was taken to Pisa by his father, who had gone thither in the vain hope of being restored by the arms of the emperor Henry VII. to his original home. Disappointed and disheartened, the father sought finally a refuge for himself and his family at Avignon, then the seat of the papal court, and in the neighboring town of Carpentras Petrarch received his first education. He early manifested a fondness for the classics; but as in that age and that country the law was the principal avenue to private emolument and political preferment, he was, when 15 years old, sent to the university of Montpellier to attend lectures on that subject. From this place he was removed in 1323 to the more famous school of Bologna. But as his passion for literature and aversion to law seemed constantly strengthening, his father hastened to the latter city to repress feelings which threatened to overthrow all his ambitious designs. Copies of the ancient authors, purchased at great cost and hastily concealed, were discovered and thrown into the fire; but the distress of Petrarch was so real, that Cicero and Virgil were rescued half burned from the flames. After the death of his parents, he left the university, and returning to Avignon found that, through the villany of his father's executors, but little of his patrimony was left. Settling at the age of 22 in that city, then one of the gayest and most licentious in Europe, the favor bestowed upon him from the fascinations of of his person and his manner led to his indulgence to some extent in dissipation; but no temptations, however strong, could turn his mind wholly or for a long time away from his favorite studies. To these he applied himself more closely than ever, the profession of the law having been given up. About 1326 he gained the friendship and patronage of Jacopo Colonna, and subsequently accompanied him to his residence at Lombes in Gascony, of which place that nobleman had been created bishop. Before this time, however, an event had taken place which exerted a controlling influence upon the after history of Petrarch. On the morning of April 6, 1327, in the church of St. Clara of Avignon, he saw a beautiful woman a few years younger than himself, with whom he at once fell violently in love. The mystery which for centuries shrouded the name of Laura was never cleared away until the investigations of the abbé de Sade, one of her descendants, who traced out almost all that is authentically known in regard to her life and character. Previously her virtue had been attacked by some, while many more had even denied her existence. In reality, Laura, descended from an ancient family, was the daughter of Audibert de Noves, a Provençal nobleman, and was born at Avignon, probably about 1308. She was possessed of a considerable fortune, and was married in 1325 to Hugues de Sade, whose temper, naturally morose, was probably not materially sweetened by the affection expressed for his wife by Petrarch, as it appears that he was in the habit of scolding her till she cried, and 7 months after her death he married again. There is no evidence that Laura ever suffered the advances of her admirer to pass beyond the bounds of propriety, although it is unlikely that she was altogether indifferent to the attentions of a lover whose praise was immortality. Certain it is that the mind of Petrarch, for the 10 years following his first sight of Laura, was agitated by a constant struggle between his passion and his reason. The summer of 1330 he spent at Lombes in the society of the bishop and of two friends, one a young German, and the other Lello de Stefani, whom he respectively named Socrates and Lælius. Returning to Avignon, he made the acquaintance of the cardinal Giovanni Colonna, and became an inmate of his palace, then the resort of a crowd of learned men and foreigners of distinction, whom political affairs constantly attracted to the papal court. Out of gratitude to that family, he undertook, but unwillingly, to superintend the education of Agapeto, the son of Stefano Colonna the younger, but seems not to have been very successful. At this time Laura, annoyed and alarmed by the assiduity of his attentions, treated him with coldness, and the fame he was gaining he found insufficient to console him. In 1333 he set out on a tour through the north of France, Flanders, Brabant, and a part of Germany, and was received wherever he went with marks of high respect. He hastened home, however, in order to accompany the bishop of Lombes to Rome; but finding that prelate had already gone thither, he remained at Avignon. When John of Bohemia made his unsuccessful expedition into Italy in 1333, Petrarch wrote an indignant epistle in Latin verse to Æneas Tolomei of Sienna, deploring the divisions existing in his native land, and bitterly inveighing against the insolence of the northern invaders. His feelings were then still more deeply stirred by the double prospect of a new crusade and of the transfer of the papal court to Rome; and when in 1334 Benedict XII. succeeded to the chair of St. Peter, Petrarch published an epistle in Latin verse seconding the prayer of the Roman embassy, that the pope would once more fix his residence in the eternal city. Benedict replied by making him canon of Lombes, but did not accede to his request. In this year he appeared in a new character. A suit had been brought before the papal tribunal by the Rossi family against the Correggios of Parma for having broken a treaty, and Azzo da Correggio, the delegate of the latter, employed Petrarch to defend his cause. The poet complied, and was successful in gaining the victory for his friend. But finding it impossible to overcome his love for Laura while in Avignon, he determined to travel, and in 1335 set out for Rome, afterward made a voyage along the southern shores of Europe, and sailed as far north as the neighborhood of the British islands. Under the excitement of travel his health and spirits returned. He now laughed at his former feelings, and, confident that his love was cured, he went back to Avignon, where a sight of Laura plunged him into a passion as fervent and as hopeless as before. It seems, however, not to have been as exclusive as it was lasting and violent, for in 1337 he had a son born to him by a woman whose name and history are alike unknown. This same person afterward bore him a daughter, called Francesca, to whom he was tenderly attached, and whom he made the heir to his property. The scandal created by the birth of a son, to one accustomed to speak with so much bitterness of the licentiousness of the western Babylon, as he frequently called Avignon, affected Petrarch greatly, and in his mortification he betook himself to the rural retreat of Vaucluse, 14 miles from Avignon. There, according to his own account, his ears were disturbed only by the sounds of nature, and within the sight of his eyes no female came save "a swarthy old woman, dry and parched as the Libyan desert." In such a solitude, relieved only by occasional visits of friends, and more frequent ones of strangers attracted by his fame, he continued his studies and his sonnets. He undertook the composition of a history of Rome, from Romulus to Vespasian; but of this work, never finished, only two fragments remain. Here also he began the Latin poem of "Africa," with his favorite Roman character, Scipio Africanus, as its hero. But his passion for Laura remained unabated, and one of his finest sonnets was occasioned by his meeting her one day in the streets of Avignon, and her saying: "Petrarch, you are tired of loving me." Among others, he composed in 1339 the celebrated 62d, 63d, and 64th sonnets, and three canzoni to the eyes of Laura, which the Italians call the three sister graces. On Sept. 1, 1340, one great wish of his heart was gratified by an invitation from the Roman senate to be crowned ed as poet laureate, and on the afternoon of the same day by an invitation from the university of Paris to receive the same honor in that city. This position he had sought for many years, and to gain it had left no means untried. The former invitation he accepted, and chose Robert, king of Naples, as his examiner, who judged him worthy of receiving the laurel, and gave him his own robe to wear on the day of coronation. On April 8, 1341, he was crowned at the capitol by the Roman senator Orso, count of Anguillara, and received letters patent entitling him to the privileges of reading and disputing, of explaining ancient books, of making new ones, of composing poems, and of wearing a crown of laurel or beech or myrtle and the poetic habit. Returning from Rome, he remained at Parma nearly a year, enjoying the friendship and society of the Correggios, who had recently gained the supreme power in that city. While there he was commissioned by the Roman people to go to Avignon for the purpose of inducing the new pope, Clement VI., to fix his residence in Rome. No more successful in this than in the former instance, he was answered by an appointment to the priory of Migliorino. He gave vent to his anger in several severe sonnets, and in a work called "A Book of Letters without a Title," in which he bitterly censured the papal court, saying, among other things, in regard to Avignon, that neither Avernus nor Tartarus could be compared with the infernal place. In the mean time he began the study of Greek, a language which was then scarcely known in Italy. The beginning of 1343 was marked by the death of his friend Robert, king of Naples, and he himself was commissioned by the pope to go to that kingdom in order to obtain from the council of regency appointed by the deceased monarch a recognition of the rights of the papal see during the minority of his daughter Giovanna. Here he was successful in gaining the favor of the young queen, who made him her chaplain and household clerk. Returning to Avignon after a short stay in Parma, he remained several years in that city or in the quiet of Vaucluse. In 1346 he was made prebendary of Parma. More important events now excited him. The revolution which in 1347 Rienzi brought about in Rome, the temporary overthrow of the lawless power of the nobles, and the establishment of order, justice, and tranquillity, promised for a time to realize all of Petrarch's dreams of what Italy might yet be. Although the Colonnas were his friends and nominal patrons, he wrote congratulatory letters to Rienzi. Toward the end of the year he went to Italy, parting for the last time with Laura, who for a long while had treated him with less reserve than before. At Parma he heard of the fate of the Colonna family, and of the fall of Rienzi. His sorrow at the sudden vanishing of his vision of Italian liberty and power was still further heightened by the news that on April 1, 1348, Laura had died of the plague, which in that year desolated Europe. Upon a copy of Virgil he wrote the following celebrated marginal note, the authenticity of which has sometimes been denied, though apparently without any just reasons: "Laura, illustrious for her virtues, and for a long time celebrated in my verses, for the first time appeared to my eyes on the 6th of April, 1327, in the church of St. Clara, at the first hour of the day. I was then in my youth. In the same city, and at the same hour, in the year 1348, this luminary disappeared from our world. I was then at Verona, ignorant of my wretched situation. Her chaste and beautiful body was buried the same day, after vespers, in the church of the Cordeliers. Her soul returned to its native mansion in heaven. I have written this with a pleasure mixed with bitterness to retrace the melancholy remembrance of my great loss. This loss convinces me that I have nothing now left worth living for, since the strongest cord of my life is broken. By the grace of God, I shall easily renounce a world where my hopes have been vain and perishing. It is time for me to fly from Babylon when the knot that bound me to it is untied." The copy of Virgil upon which this was written, after having passed through several hands, remained for a long while in the Ambrosian library of Milan, but was afterward carried to France, and has now for some time been in the imperial library at Paris. Petrarch's devotion did not stop short on this side of the grave. The last half of the *Canzoniere* is a tribute to the memory of the dead Laura, more real and more affecting than the living Laura ever received. Twenty years after, when near his own end, he depicted Laura as appearing to him in a mist, and giving the reason for her varying conduct, in answer to his question as to whether she ever loved him. "It was by this alternation of kindness and rigor," she is described as saying, "that I have led thee, sometimes happy, sometimes unhappy, often wearied in truth, but still I have led thee to where there is no more danger, and I have thus saved us both. There has been little difference in our sympathy, except that thou didst proclaim thine to all the world, and I concealed mine. But complaint does not embitter suffering, nor does silence soften it." At the request of Luigi Conrado of Mantua, he stayed for a time in that city, and also in Padua and Verona. He wrote a letter at this time to Charles IV. of Germany, entreating him to come into Italy and restore peace to that country. In 1350, the year of jubilee, he visited Rome, and after this period he tells us that he subdued his mind by religious reflections so as to be proof against all female fascinations. Certain it is that henceforth his manner of life became more austere, and his thoughts and writings of a graver cast. His friendship for the Carraras led him to remain in Padua during the following winter, and while there he occasionally visited Venice, and became an intimate friend of the doge Andrea Dandolo. To him he addressed in March, 1351, a long letter, praying that he would put an end to the war with the Genoese, then just begun, and predicting that if it were prosecuted disasters would befall both states. In April his friend Boccaccio arrived from Florence, and announced to him the recall of his family to their native city, and the restoration of his ancestral property. He was offered the directorship of the university recently founded in Florence, but this honor he declined. In May he set out for Provence, and reached his transalpine Parnassus, as he called Vaucluse, about the end of June. There he set about the composition of his "Epistle to Posterity," in which he narrated the events of his life down to the middle of 1351. In the summer of 1352 Rienzi was brought a prisoner to Avignon, and being refused an advocate to defend him, Petrarch was extremely indignant, and is said to have written the appeal to the Romans in behalf of their tribune, which is found in his "Epistles without a Title." If written by him, it was probably never published. Clement VI. being near his end at this time, Petrarch wrote him a letter, which brought the medical faculty up in arms against the poet. He advised the pope to send away his physicians, and to consider the whole crowd of them attending him as his enemies. The attacks made upon him for this letter led to his writing his "Four Books of Invectives against Physicians." In May, 1353, he again set out for Italy, and at the pressing invitation of Giovanni Visconti he settled in Milan. His friends were grieved that a man so professedly a lover of independence and hater of tyranny should seem to ally himself with the lord of Milan, dreaded throughout Italy for his power, and detested for his ambition. He received many reproachful letters, and in particular a very severe one from Boccaccio. In reply he sometimes defended himself, at other times confessed that he was entirely in the wrong. The utter defeat of the Genoese by the Venetians off Lughiera, in Sardinia, on Aug. 17, 1353, filled him with dismay, and prompted him to write a letter to the vanquished people; but their sudden submission to the Viscontis prevented the letter from ever being sent. A league was now formed between Venice and the princes of Padua, Modena, Mantua, and Verona against the lords of Milan; and in Jan. 1354, Petrarch was sent to the first named city to make peace. He was unsuccessful in his mission, and though both Giovanni Visconti and Dandolo died soon after, the war went on. A truce was negotiated between the belligerents by the emperor Charles, who, in Oct. 1354, crossed the Alps, and during his stay at Mantua treated Petrarch with great favor. In 1356 Petrarch was sent by the Viscontis to Germany, nominally to justify them in the emperor's eyes, but really to penetrate into his designs and to dissuade him from coming to Italy. After his return he received a diploma, in which Charles created him a count palatine. In the summer of 1357 he settled at Garignano on the Adda, near Milan, and 1359 was spent principally in the composition of his "Remedy against either Extreme of Fortune." In 1360 he went to Paris, in behalf of Galeazzo Visconti, to congratulate King John upon his restoration to liberty. In 1361 he fixed his residence in Padua. During this year his son, Giovanni, who was very dissolute and had cost him much grief and trouble, died; and his daughter was married to Francesco di Brossano, a gentleman of Milan. The plague, which had begun to reappear in various parts of Italy, forcing him to leave Padua, he went to Venice, and to that city gave his books on condition that they should be placed in safety and should neither be sold nor separated. The republic assigned him a residence in a palace called the "Two Towers," and lodged his manuscripts in the church of St. Mark, where some of them are still to be seen. During his stay in Venice he was visited by Boccaccio, driven from Florence by the plague, who brought with him his teacher in Greek, Leontius Pilatus, a Calabrian. Petrarch began once more to learn that language, seeking relief in study from the sorrow by which he was assailed. His old and attached friends were all disappearing, and his eminence had not saved him from the attacks of enemies. In the bitterness of his heart he is said to have wept over his laurels, and to have owned that his crown had been to him nothing but a crown of thorns. In 1368 he removed to Padua, and at the request of the pope, Urban V., attempted to visit Rome in 1370; but being taken sick at Ferrara, he was obliged to give up the journey. He now went to reside at Arqua in the Euganean hills, where he resumed his old habits of labor, keeping 5 or 6 amanuenses, and paying no attention to the advice of his physician. Here also he finished a work entitled *De sui ipsius et aliorum Ignorantia*, written against some disciples of Averroes, who at Venice had annoyed him by their opinions, and who, because he did not yield to the authority of Aristotle, had judged him to be illiterate. In 1373 Francesco da Carrara was obliged to make a humiliating peace with Venice, one of the conditions of which was that he should come in person to that city or send his son to ask pardon for the insults he had offered. He asked Petrarch to accompany his son and address the senate in his behalf. The poet was old and infirm, but he remembered only his ancient friendship for the Carraras, and set out. The first day he was unable to utter a word; but on the second he spoke with something of his accustomed fire. It was his last appearance in public life. After his return to Arqua, he read for the first time Boccaccio's "Decameron," learned the story of Griseldis by heart, turned it into Latin, and sent the version to the author, with a letter, apparently the last he ever wrote. One morning he was found dead in his library, with his head reclining upon an open book. He was buried in the parish church of Arqua.—Petrarch's works may be divided into three kinds: Latin prose, Latin poetry, and Italian poetry. Beside those already mentioned, there are of the first named the following treatises: *De Vita Solitaria*, written in defence of his own love of retirement; *De Otio Religiosorum*, written in 1353 after a visit to his brother, who was a monk; *Apologia Authoris contra Calumnias Galli; De Officio et Virtutibus Imperatoris; Rerum Memorandarum*, a collection of facts from ancient and modern history to illustrate some ethical principle; *De Vera Sapientia; De Contemptu Mundi*, an imaginary dialogue between himself and St. Augustine, which he considered so important as to call it his secret; *Vitarum Virorum Illustrium Epitome; De Republica optime Administranda*, a collection of the principal maxims of Plato and Cicero on politics; *De Vita Beata; De Obedientia ac Fide Uxoria; Itinerarium Syriacum;* several orations, and his epistles. The last named are the most important and interesting of his prose works; they are rich in materials, hitherto never fully used, for the history of the stormy times in which he lived, and in many of the scenes of which he was an actor. His Latin poetry consists of his epic of "Africa;" of 3 books of "Epistles" addressed to his friends, or to various popes, urging their return to Rome; and of 12 "Eclogues," like those of Boccaccio, allegorical, and being really satires against men in power, especially against the papal court of Avignon. At the same time the point of the satires has been in some instances so studiously concealed, that it has baffled all inquiry to discover against whom or what they were aimed. The suspicion which has at times sprung up from expressions in these "Eclogues," that he was a secret enemy of the Roman Catholic church, is wholly unfounded, as his invective is always directed against the abuses which had crept into the church discipline, and not against the doctrines or rites of the church itself. The poem of "Africa," whose general dulness and decent debility are occasionally varied by fine passages, is now rarely read, and never praised, though it gave him in his own age his chief reputation among the noble and the learned. At one time he himself deemed it the greatest of his works. His Latin style, though superior to any other of his age, is neither elegant nor accurate, and is condemned by Erasmus. But whatever his merits or defects as a writer of Latin, as the restorer of classical literature in Italy, and therefore in Europe, his services are unquestioned. He was unwearied in the collecting and copying of ancient manuscripts, but for his efforts many of which would probably have perished. He discovered at Arezzo the "Institutes" of Quintilian; at Verona, the "Familiar Letters" of Cicero; the "Epistles to Atticus," and other ancient writings, beside speaking of having seen some which are now lost. It was Petrarch's ambition to write elegantly in a dead tongue; it was his good fortune to perfect a living language. To the Italian he gave harmony, purity, and even stability; and so wonderfully did he use its resources, that even now scarcely an obsolete word can be found in his writings. His Italian poetry is called *Il canzoniere*, or *Rime di Petrarca*, and consists of over 300 sonnets, about 50 *canzoni*, and 3 short poems in *terza rima*, called *Trionfo d'Amore*, *Trionfo della morte*, and *Trionfo della fama*. The *canzoni* are odes the form of which was borrowed from the troubadours, and the contents of which are usually of a more elevated character than the sonnets. The latter half of the *Canzoniere* is universally regarded as the superior. The fame to which his Italian poetry attained in his own age surprised Petrarch; but great as it was, it was far below the admiration accorded by later times. In 1540 the academy of Florence was founded with the avowed object of illustrating and perfecting the native tongue, and the works of Petrarch were taken as the model by which èvery thing was judged. One sonnet would sometimes be made the subject of a volume, and every word of it the subject of a commentary. To this careful study and imitation of Petrarch, though carried to a ridiculous excess, the Italian writers of the 16th century owe the elaborate elegance of their style. A historical work of Petrarch, entitled *Le vite de' pontefici ed imperatori Romani*, appeared at Florence in 1478, and is now very scarce, although much sought after as one of the earliest specimens extant of Italian prose. The most ancient edition of his Latin works is that of Basel (fol., 1496), and the most complete is that of the same place published in folio in 1581. His letters and autograph manuscripts, many yet unedited, are to be found in the public libraries of Italy. In later times his Italian poetry has usually been printed by itself. There are over 300 editions of the *Canzoniere*, with and without commentaries, of which the best is that of Marsand (2 vols. 4to., Padua, 1819–'20). Of the commentators upon his works, the most conspicuous are Vellutello, Gesualdo, Castelvetro, and, in later times, Tassoni, Muratori, Biagioli, and Leopardi. In 1828 Domenico de' Rosetti published at Trieste a bibliography of his works, with their various editions and commentaries. There are said to be more than 25 distinct biographies, of which the most important are those of Vellutello, Beccadelli, Tomasini, De la Bastie, De Sade, Tiraboschi, Baldelli, Ugo Foscolo, and Thomas Campbell. Very little of Petrarch has been translated into English. The *Trionfi* were versified by Boyd (1807), and the odes and sonnets by Dr. Nott (1808), Archdeacon Wrangham (1817), Fraser Tytler (1810), &c. The first complete translation, by various authors, of Petrarch's Italian poems, forms a volume of Bohn's "Illustrated Library" (London, 1860).

PETREL, the common name of the web-footed oceanic birds constituting the sub-family *procellarinæ*, characterized by tubular nostrils, placed on the basal portion of the culmen and opened in front; the beak as long as the head, straight, more or less compressed, grooved as if composed of several pieces, with the tip strong, arched, suddenly hooked, and acute. The best known genera are *procellaria* (Linn.), the petrels proper, and *thalassidroma* (Vigors), the stormy petrels. The general form of the body is like that of the gulls, but the feet have a very rudimentary hind toe, and the beak is very different, the apical being distinctly separated from the basal portion; the habits also are like those of the gulls, but more oceanic, as they pass most of their lives in skimming over the surface of the waves; they rarely visit the shore except for the purpose of breeding, and then select rocky shores, depositing their eggs on the bare rock. They have a habit of running with closed wings upon the surface of the waves; this faculty has been compared to the walking of St. Peter upon the sea of Gennesareth, and hence the title of this bird, which is a diminutive of the apostle's name. The flight is rapid, powerful, and continuous, the same birds following vessels for many successive days; they sail along with extended wings, without flappings, and with apparently little motion; the higher the wind and the more agitated the sea, the more abundant are these birds, as at such times the crustaceans, mollusks, and other marine animals upon which they principally feed are most easily obtained; from this habit is derived the superstition of sailors that they are the harbingers of a storm.—In the genus *procellaria* the wings are long and pointed, the first quill the longest; the tail moderate and rounded, tarsi shorter than the middle toe, toes long and fully webbed and the lateral ones margined externally, the hind toe a mere triangular claw. The giant petrel (*P. gigantea*, Gmel.; genus *ossifraga*, Homb. and Jacq.) is about 3 feet long and 7 in alar extent, at a distance resembling a small albatross; the plumage is dense, full, and elastic, and the head is wholly feathered; the color above is brownish gray mottled with dusky white, the wings and tail dusky brown; lower parts white; bill, legs, and feet yellow. Common in the southern ocean, it is sometimes seen on the Pacific coast of North America as far up as Columbia river in spring and summer; it is very rapacious, attacking and tearing to pieces the smaller petrels and young gulls; it lays its eggs on the sandy shores of the Falkland islands, where it occurs in immense numbers; the young are fed with oily matters which the parents eject from the stomach for the purpose. The fulmar petrel (*P. glacialis*, Linn.; *fulmarus*, Leach) is about 20 inches long, with an alar extent of 3 feet and a weight of 1¼ lbs.; the bill, iris, and feet are yellow, the latter with a greenish tinge; the head, neck, and lower parts pure white; back and wings light grayish blue, paler on rump, and the tail bluish white; quills and their coverts blackish brown; a black spot before and partly over the eyes. It is abundant in the arctic seas, where it attends the whale ships, seizing the pieces of blubber which fall into the water, and often boldly helping itself from the carcass while the men are at work; it breeds in the northern regions, coming down on the American coast as far as Long Island in the autumn, winter, and early spring, and is pretty common on the banks of Newfoundland, where it feeds on the garbage rejected by the cod fishers. It also breeds in the island of St. Kilda, on the W. coast of Scotland, where the inhabitants eat the flesh and eggs, preserve the down and feathers, and collect the oil vomited by the birds when seized, or obtained by boiling down the young, which is used for burning and for medicinal purposes; the eggs are pure white, with very brittle shells, regularly ovate, 2¾ by 2 inches, and are obtained with great difficulty and danger, as the nests are in the crevices of nearly perpendicular rocks. These are bold and powerful birds, rapid and graceful fliers, excellent swimmers, but awkward on land; they rarely dive; they are hardy, difficult to kill from the thickness of the plumage, and can inflict severe wounds with the bill. Other species found on the American coast are the Pacific, slender-billed, and tropical petrels, respectively the *P. Pacifica*, *tenuirostris*, and *meridionalis*, the first two found on the Pacific coast, and the last on the Atlantic from Florida to New York. The pintado petrel, or Cape pigeon (*P. Capensis*, Linn.; genus *daption*, Steph.), is about 15 inches long; the general color is white above varied with brown; the upper part of head and hind neck plumbeous black, smaller wing coverts the same, tipped with brown, the larger white margined with black; primaries white on the inner web and black on the outer; secondaries and tail white with dark tips; lower parts white; bill black. This species is abundant in the southern ocean, with the albatross and other petrels; it has been seen on the coast of California. More than 20 other species are described.—In the genus *thalassidroma* the bill is shorter and more slender and weak; the nostrils open by a single tubular aperture, as in the preceding genus; the 2d quill is the longest, the tail more or less forked, the legs long and slender, with an extensive bare space on the tibia, tarsi longer than the middle toe, and the hind toe a small claw. The species, about a dozen, are of small size, inhabiting the surface of the sea in both hemispheres, skimming lightly and irregularly over the waves, floating buoyantly upon them, or running along the tops; they follow vessels for great distances, feeding upon the greasy matters thrown overboard and on minute marine animals; they are of a dark color, more or less marked with white, and are popularly called Mother Carey's chickens and sometimes sea swallows. The common stormy petrel or Mother Carey's chicken (*T. pelagica*, Vig.) is about 5¾ inches long, with an alar extent of 10½, the bill and feet are black; the color is grayish black above tinged with brown; below sooty brown; secondary coverts margined with grayish white, and quills black; rump and upper tail coverts white with black shafts, the tail coverts broadly tipped with black. They are thought by sailors to forebode stormy weather, and are therefore dreaded and scrupulously unmolested; they occur in most parts of the temperate Atlantic, and are common about the banks of Newfoundland with the other species. They breed on rocky shores and islands in the N. Atlantic, on St. Kilda, and the Shetland islands; in the latter they begin to lay toward the end of June, depositing a single egg in a nest made of plants and earth, carefully concealed, sometimes at a depth of 3 or 4 feet, under the stones on the beaches; they remain quiet by day, becoming active about twilight; the eggs are 1⅛ by ⅞ inch, white, with minute dull red dots at the larger end. According to Brünnich, this bird becomes so fat that the inhabitants of the Färöe islands string it to a wick, and use it as a lamp. Other species of this genus found in America are the fork-tailed petrel (*T. furcata*, Gould), wholly bluish gray, with legs and feet brown; it is about 8 inches long, and is found on the coasts of Oregon and Russian America; Leach's petrel (*T. Leachii*, Bonap.), sooty brown, with white rump, tail forked, and tarsi and feet black, found from Massachusetts to Baffin's bay; Wilson's petrel (*T. Wilsonii*, Bonap.), differing from the last in the darker color of the brown, the slightly emarginate tail, and the yellow color of the basal two thirds of the webs; the black petrel, on the coast of California (*T. melania*, Bonap.), entirely black above and sooty below.—In the genus *pelecanoides* (Lacép.) the bill is shorter than the head, broad, depressed, and swelled at the sides; beneath the bill is a membranous pouch capable of extension; nostrils opening by 2 tubular apertures; wings very short, as are the tarsi and tail; toes long, the hind one wanting. A few species are described, inhabiting the coasts of New Zealand, Australia, and the extreme parts of South America; they are seen in troops, and dive very frequently, probably in search of small fish; they are rather poor fliers, compared with other petrels.—In the genus *prion* (Lacép.) the bill is longer, depressed, with nearly straight culmen, sides dilated near the base and beset posteriorly with fine parallel laminæ; nostrils with 2 openings, short and elevated; the hind toe a mere claw. The broad-billed petrel (*P. vittatus*, Lacép.), found between lat. 35° and 70° S., is bluish ash above, with tips of quills and wing coverts black; it is wild and solitary, a rapid flier, and constantly on the wing; the nests are made in society, in burrows of about a yard deep, excavated in the sides of hills near the sea; the eggs are white, elongated, like those of a pigeon; some of the characters of the bill resemble those of the fishing ducks.—For the genus *puffinus* (Briss.) see SHEARWATER.

PETRIFACTIONS. See PALÆONTOLOGY.

PETROLEUM (Lat. *petra*, a rock, and *oleum*, oil), rock oil, a natural product of the soil in some countries, oozing up from below the surface, and flowing out with the water springs. As it occurs in nature it is of no definite composition, but consists of various oily hydrocarbons, which hold in solution paraffine and more or less solid bitumen or asphaltum. When of the greatest fluidity they resemble naphtha, and have been called by this name, and also oil of naphtha. As the proportion of asphaltum increases, the mixture becomes thicker and darker, resembling tar in appearance; and at length, by further diminution of the fluid ingredients, it passes into asphaltum. Tar lake in Trinidad, described in the article BITUMEN, consists of asphaltum with not enough petroleum to keep the whole fluid at ordinary temperatures. Such mixtures are of little value; but the liquid oily bitumens in some countries are very important products, and in the United States have become so since the article referred to was printed, three years ago (1858). The various forms of these substances were known to the ancient Greeks and Romans, and by Tacitus, Pliny, Vitruvius, and other Roman writers were designated *bitumen*, a word derived from the Greek *πιττα*, *πισσα*, pitch, and probably first written *pitumen*. Among the localities cited, where the liquid bitumen was found, is one of the Ionian islands, Zacynthus, now Zante. Being referred to by Herodotus, this spring must have been flowing more than 2,000 years, and how long before his time we know not. At Agrigentum in Sicily the petroleum was collected and burned in lamps as a substitute for oil. (Dioscorides, i. 99.) The origin of these fluids is very obscure. They appear to be of organic nature, and do not differ from products distilled from bituminous shales and coal; but they are found in geological formations which were not repositories of great bodies of vegetable or animal substances, and are rarely met with in proximity to beds of coal. Around volcanoes petroleum is often seen floating upon the surface of the water, as around the volcanic isles of Cape Verd; and to the south of Vesuvius a spring of it rises up through the sea. Everywhere it is accompanied by springs of common salt, and by jets of carburetted hydrogen gas. The following are some of the most noted localities of it: Amiano and other places in the north of Italy, which have furnished the supplies used for lighting the cities of Parma and Genoa; Bakoo in Georgia, on the borders of the Caspian; Rangoon in Burmah; the island of Trinidad; and portions of Pennsylvania, Ohio, New York, &c.* In northern Italy, in the duchies of Parma and Modena, petroleum has been extracted from the earth since its first discovery in 1640, the method pursued being merely to sink pits in the ground, and collect the fluid that exuded from the soil in little basins or reservoirs in the bottom of the pits. The various sorts were gathered from different localities, and their peculiar properties appear to have been correctly observed; but no methods of purifying them were employed; on the contrary, the lighter and better oils were made the medium of utilizing the poorer sorts by mixture. The W. shore of the Caspian (see BAKOO) has been celebrated from a remote period for the extraordinary quantities of inflammable gases and liquids that rise from the surface of the ground. They are met with over a tract of country about 25 m. in length and about ½ m. in width, in strata of a porous argillaceous sandstone belonging to the tertiary period. In the vicinity are hills of volcanic rocks through which springs of the heavier sorts of petroleum flow out. The oil is collected by means of large open wells sunk 16 to 20 feet in depth, and in these it gathers as it oozes out from the strata. It is observed that the oil from the central portion of the tract is clear and pure as if distilled, and by its faint yellow tint resembles Sauterne wine. That obtained nearer the sides of the tract is darker, gradually changing to a yellowish green, then reddish brown, and finally to asphaltum. The quantities annually collected and sold amount in value, as stated by M. Abich in his work on that country, to 9,000,000 francs; and the sales might easily be made to double this extent. The oil is introduced very largely into Persia, and over large districts there no other material is used for producing artificial light.—The Rangoon district on the Irrawaddy is quite as wonderful for its immense production of rock oil as Bakoo. For an unknown period the whole Burman empire and a considerable portion of India have been supplied with oil from this source. The trade is carried on by means of large boats that come up the Irrawaddy to the town of Rainanghong, a place inhabited by potters, who are constantly making the earthen jars in which the oil is kept. These are piled up in great pyramids about the town ready for use. The wells are in beds of sandy clays which rest on sandstones and argillaceous slates, and are sometimes sunk to the depth of 60 feet. Under the slates is said to be coal; but this and the other strata may be of the tertiary epoch. Symes ("Embassy to Ava," vol. ii.) states that the number of wells in this district exceeded 520, and the annual yield of petroleum was more than 400,000 hogsheads. The natives use the oil in lamps, for preserving timber against insects, and as a medicine. It has recently been imported into England, in metallic tanks to prevent its volatile portions from escaping; and at the great candle factory of Messrs. Price experiments have been made to test its qualities for affording paraffine for candles. The material is described as of semi-fluid consistence, like goose grease, its color greenish brown, and its odor peculiar but not disagreeable. Distilled with steam at successively increasing temperatures below 500° F., the fluid hydrocarbons that came over were almost free from paraffine; but the products which required a temperature of 612° and upward solidified on cooling and contained most of the paraffine, which might then be separated by pressure. Its total proportion is from 10 to 11 per cent.—The occurrence of petroleum about the head waters of the Alleghany river in New York and Pennsylvania was known to the early settlers of that region. The Indians collected it on the shores of Seneca lake, and it was sold as a medicine by the name of Seneca or Genesee oil. A stream in Alleghany co., N. Y., was named Oil creek in consequence of the appearance of oil in its banks; and the same name was given to another branch of the Alleghany river in Venango co., Penn. Several localities are designated upon the old maps of this part of the country as affording oil; and upon Oil creek in Venango co. two spots were particularly noted, one of which was close to the N. line of the county, and one about 12 m. further down the stream. At these points springs issued from the banks of the stream, bringing up more or less oil, which collected upon the surface of the water as it stood in the pools below the springs. The inhabitants were accustomed to collect the oil by spreading woollen cloths upon the water, and wringing them when saturated. Down the valley of this creek there are numerous ancient pits which appear to have been excavated for the purpose of collecting oil, but by whom made no one can now tell. From the fact that logs have been found in them notched as if with an axe, some have supposed that the work was done by the French, who occupied this region in the early part of the last century; but others believe that the Indians, who are known to have valued the oil, dug the pits. Day, in his "History of Pennsylvania" (1844), gives an account of the estimation in which they held this product, using it mixed with paint to anoint themselves for war, and also employing it in their religious rites. He quotes an interesting letter from the commander of Fort Duquesne to Gen. Montcalm, describing an assembly of the Indians by night on the banks of the creek, and in the midst of the ceremonies their firing the scum of oil that had collected upon the surface of the water. As the flames burst forth, illuminating the dark valley, there rose from the Indians around triumphant shouts that made the hills reecho again. The scene recalled to the writer the accounts of the ceremonies of the Guebres or ancient fire worshippers of the sacred city of Bakoo. The quantities of oil collected by the early settlers were unimportant, the largest amount, which was from the lower spring on Oil creek, reaching sometimes 20 barrels in a year. No suspicion appears to have been entertained that the supplies could be increased by sinking deep wells through the sandstones and shales that underlay the valley; and it was not known that by distillation and chemical treatment the quality of the petroleum could be greatly improved. Even when, in boring for salt near Tarentum, 35 m. above Pittsburg on the Alleghany river, springs of petroleum were struck in 1845, the material was valued only as a medicine, and for this use has been ever since retailed in small quantities at high prices. In Ohio, on the Little Muskingum, the inhabitants narrowly missed learning the importance of this product as far back as the year 1819. Dr. S. P. Hildreth of Marietta, in an account of the region written in that year and published in the "American Journal of Science" (1826), speaking of the borings for salt water, says: "They have sunk two wells, which are now more than 400 feet in depth; one of them affords a very strong and pure water, but not in great quantity. The other discharges such vast quantities of petroleum, or as it is vulgarly called 'Seneka oil,' and beside is subject to such tremendous explosions of gas as to force out all the water and afford nothing but gas for several days, that they make but little or no salt. Nevertheless the petroleum affords considerable profit, and is beginning to be in demand for lamps in workshops and manufactories. It affords a clear, brisk light, when burnt in this way, and will be a valuable article for lighting the street lamps in the future cities of Ohio." It is not a little singular that, with the sources of supply thus pointed out and the useful application of the petroleum understood, its value should have remained unappreciated, and at the expiration of more than 35 years be at last perceived through the progress of experiments made upon the distillation of bituminous shales and coal. The success attending these, and the identity of the crude oil with the natural petroleum, caused attention to be directed to the sources of this with the view of testing the capacity of the supplies, and applying to the natural oil the methods of purification invented for the artificial. The first movement made in this direction was in 1854, by Messrs. Eveleth and Bissell of New York, who secured the right to the upper spring on Oil creek, and organized a company in New York. The quality of the oil was tested and a report made upon it by Prof. B. Silliman, jr. No progress, however, was made in establishing the business until Dec. 1857, when Messrs. Bowditch and Drake of New Haven undertook to search for the oil. Col. E. L. Drake removed to Titusville on Oil creek, and in the winter of 1858–'9 completed his arrangements for boring into the rock below the bed of the creek. The work advanced very slowly, and it was not until Aug. 26, 1859, that oil was struck at the depth of 71 feet. The drill suddenly sank into a cavity in the rock, and the oil rose within 5 inches of the surface. A small pump being introduced, a supply of oil was obtained, amounting to 400 gallons a day; and a larger pump being afterward substituted, the flow was increased to 1,000 gallons a day. Though a steam engine was applied to the work and kept in constant operation, the supply continued uninterrupted for weeks. This success gave a new value to every spot where oil had ever been found or was thought likely to produce it. The narrow valleys of the water courses, excavated 300 or 400 feet through the piles of horizontal strata, had been its natural outlets, and along these great numbers of wells were soon commenced. Oil creek below Titusville, the valley of the Alleghany from below Franklin up into Warren co., and the banks of French creek, were soon explored by wells, and around the most successful of these villages rapidly sprung up, and extraordinary business activity was introduced into regions that had been among the most retired and quiet portions of the state. Next to Oil creek the valley of the Alleghany, from Tidioute in Warren co., S. to the Venango line, contained the most productive wells, and others of great yield were opened in the town of Franklin. So numerous were these undertakings, that the village presented a curious aspect with the numbers of tall derricks, employed in boring the Artesian wells, scattered among the gardens and house lots. Before the close of the year 1860, according to one published statement, the number of wells had amounted to full 2,000, and 74 of these were producing daily as follows:

---

* Springs of it are reported by Capt. Stansbury on a branch of Yellow creek, 83 m. from Salt Lake City, on the route toward Fort Leavenworth, Kansas. They occur near a bed of bituminous coal and near several sulphur springs. The emigrants, he observes, collect the petroleum for medicinal purposes and for greasing their wagon wheels. (Stansbury's "Exploration and Survey," Senate Documents, 1851, p. 226.)

Locality.	No. of wells.	Product, bbls.
Oil creek	33	485
Upper Alleghany river	20	442
Franklin	15	139
Two Mile Run	3	64
French creek	3	35
Total	74	1.165

The barrels holding 40 gallons each, the daily yield of these wells was by this estimate 46,600 gallons; and of the whole district it probably exceeded 50,000 gallons. At 20 cents per gallon, to which the price of most of the oil had fallen on the spot, the value of the daily product was $10,000. The productive wells vary greatly in depth. In some large supplies are afforded at 60 or 70 feet, and in others at greater depths to over 500 feet. Most of the oil is from wells over 180 feet deep and less than 280. Shallow wells, that are exhausted by pumping, are often made to yield again by sinking them deeper. Several wells may continue in successful operation near together without seeming to draw upon each other; and again wells may be sunk near others that are producing largely, or near the natural springs of oil, and prove unsuccessful. The pumps are sunk deeper into the wells as the supply goes down; and it is observed that if the pumping is interrupted for a day, the product obtained when it is re-owed will be water, which is more or less salt. At some wells the flow of water has continued during several days' pumping before the oil was recovered. This never seems to fail entirely, unless it be from some obstruction arresting the flow, and then recourse is had to sinking deeper or enlarging the bore of the hole. Salt water commonly comes up with the oil, and is separated from it by standing in the vats into which the products are received. The proportion of this to the oil is very variable, and the quantity of oil daily pumped from a single well is far from being regular. A yield of 10 or 15 barrels a day is common, and some wells have averaged 50 barrels for a considerable time. Instances have occurred of the oil, when first struck, rushing up with great violence by reason of the pressure of the carburetted hydrogen gas that accompanies it; the effect being like that attending the uncorking of a bottle of fermented liquor. At one well near Tidioute it is stated that a workman was knocked over by the jet of oil, which was thrown up through the derrick and into the trees around. The open well around the tube was filled by the overflow, and 100 barrels or more of oil, it was supposed, escaped into the river.—Beside the localities already noticed, several other places have recently become known for their oil wells. Upon the margin of the coal field in Trumbull co., Ohio, at a place called Mecca, 50 m. from Cleveland and 21 from Erie, Penn., wells were first sunk in the spring of 1860, the encouragement for making the trial consisting in the fact of the water in the wells being strongly impregnated with oil. Petroleum was soon obtained at the depth of 50 feet; and in November of that year it was stated that over a small district from 600 to 700 wells had been sunk, and 75 steam engines were in operation pumping oil. In Allegany co., N. Y., about a mile N. W. from the town of Cuba, operations were commenced about the first of Jan. 1861, near a famous great pool, which had always been known as the oil spring. Before the iron pipe driven into the ground had reached the rock, oil mixed with water gushed violently up through it. From another well sunk in the rock near by more oil has also been procured. In Virginia wells are in successful operation in Ritchie and Wirt cos. In Canada West also oil has been obtained for the last two years, which is remarkable for its peculiarly offensive garlicky odor.—The process of sinking the wells does not differ essentially from that described under ARTESIAN WELLS. But the mode of securing an opening down to the rock is novel and ingenious. In the creek bottoms the excavation and walling of an open well is troublesome on account of quicksands, and those which have been made through the superficial covering of sand, gravel, and clay have necessarily been large and their sides secured by timbering, as practised in mining shafts. To avoid this trouble, strong iron pipes of 4 to 6 inches diameter, made for the purpose, are driven through the soil down to the rock, one pipe bolted upon the top of another, to any depth required, which is usually not more than 22 feet. If obstacles are encountered that cannot be pushed aside even after being broken up by the drills working through the pipes, the work is abandoned in that spot and commenced in another. The derricks erected for supporting the apparatus for drilling, and afterward that for pumping, are pyramidal structures of 4 corner posts, 30 or 40 feet long, framed together so as to include a square of 10 to 14 feet on the sides on the ground, and of 4 or 5 feet at the top. Covered with boards, they make a convenient shelter for the workmen. The drills are worked either by men or by horse or steam power. A stiff spring pole firmly secured at one end lifts the drill and rods suspended from its free end, and the power is applied at this end to make it suddenly descend. When managed by men, two standing together place each a foot in a double stirrup suspended from the pole and suddenly bear it down. Immediately it springs up, and they repeat the operation.—The source of the petroleum is an interesting question, particularly as it bears upon the probable permanence of the supply. Though we obtain the rock oil artificially only from bituminous shales and coal, its occurrence is not always limited to localities where large bodies of these formations are known to exist. On the contrary, springs of it issue in different parts of the world from all the stratified rocks, and from the volcanic and metamorphic formations. It is sometimes traced to beds of lignite, and sometimes its source is altogether obscure. In Ohio and Virginia it is found in the coal measures, and the wells are in some instances sunk through these into the sandstones and slates beneath before they become productive. In N. W. Pennsylvania or in New York the wells are entirely outside of the coal field, and so remote from it that we cannot well imagine any connection between the oil and the coal beds. The strata in which the oil is found dip S. and pass below the coal measures at least 500 or 600 feet, the nearest coal bed to the more northern springs occurring in the tops of the highest hills, perhaps 30 m. distant. The conglomerate which underlies the coal formation caps some of the hills in the oil region, and attains a thickness of from 100 to 300 feet. The shales and sandstones that succeed below this rock belong to the Chemung and Portage groups of the New York geologists, and extend over a large portion of southern New York, to the W. of Binghamton, and of N. W. Pennsylvania. The oil wells are bored in this group through alternating layers of shales and sandstones, and an occasional stratum of a bluish sandy limestone. The next group below is that known as the Hamilton shales in New York, and in Ohio as the black slate. Dr. Newberry of Ohio considers this the source which affords the petroleum. It contains much carbonaceous matter, and is supposed by him to be amply sufficient for generating the supplies that are forced upward from it by the water that finds its way beneath the oil, and by the pressure of the carburetted hydrogen gas also furnished from the same source. It is from these slates that the oil springs of Canada West issue, and these are far distant from the coal formation. Through the open seams, that are common in the shales and sandstones, the oil currents find a passage, sometimes coming out to the surface; and it is owing to the irregularities of these seams that wells sunk near together vary in their yield, in the depth at which they become productive, and even sometimes, as in the Kanawha region of Virginia, in the quality of the oil they afford. Although nothing certain can be predicated of the capacity of the supply, and actual experience alone can determine this question, there is certainly abundant encouragement for expecting a large and long continued production from the great extent of the oil region, and from the history of the oil districts of Bakoo and Rangoon, which, though drawn upon for centuries, have never failed to furnish the immense supplies demanded of them. Single wells will continue to fail as they have done, but new ones will renew the supply, and the old may recover that which they have lost. It seems impossible that as a whole the business can fail to continue to be one of great importance.—Petroleum of different localities varies considerably in character. The substance is ordinarily of a greenish hue, more or less deep and opaque; but some varieties of light clear oils have a reddish color. All have a disagreeable smell, which is not completely removed by the ordinary process of purification. Their quality is indicated by their specific gravity, and this is taken by Baumé's hydrometer, the higher degrees of which mark the lighter oils, such as are most esteemed. The best are some of those of Oil creek, of 46° B. Others of the same district increase in density to 38°. At Tidioute oils are obtained of 43°. At Franklin they rate from 33° to 36°, and on French creek also they are heavy. At Mecca they are dark, thick, and heavy, so that when cold they refuse to flow. Their density is 26° or 27°, corresponding to a specific gravity of about 0.90. The oil from Cuba, N. Y., resembles that of Franklin, marking 32°.—In the rectification of petroleum the light oils that first come over are often called benzole, and are sold, put up in small quantities, for some of the purposes to which benzole is applied, as removing grease spots from fabrics; but no real benzole is ever a product of the distillation. The proportion of light oils suitable for illumination amounts in the very best petroleum to 90 per cent., which however is rarely obtained; and from this the yield diminishes to 80 per cent. or even a lower proportion. The heavy oils separated from the lighter are of comparatively little value. They are used for lubricating machinery, and for this purpose are advantageously mixed with about an equal proportion of lard oil, the petroleum imparting to the mixture its useful property of not congealing at low temperatures, and also correcting the tendency of the latter to gum, while the lard oil imparts body to the mixture, in which the petroleum is deficient. They have also been applied in woollen factories to the cleansing of the wool, and where thus used a preference is already given to them over other oils. Paraffine, which remains with the heavy oils and is separated from them by condensation at low temperatures, filtering, and pressing out, as stearine is separated from lard, is of variable proportion, averaging perhaps a pound to 4 gallons of the petroleum. The heavier oils do not produce it in larger proportion than the lighter, and some of them, which appear to be isomeric with paraffine itself, afford very little of it. (See PARAFFINE.)—Petroleum acquired a reputation as a medicine before it was used for other purposes; and there is no doubt it possesses some virtue, especially as an outward application in diseases of the skin, chilblains, rheumatism, &c. Taken internally in doses of 30 to 60 drops, it acts as a sudorific and stimulating anti-spasmodic. It has been recommended for disorders of the chest, and in Germany as a remedy for tapeworm.—REFINING. The processes employed in refining petroleum are the same as those devised for the rectification of the crude coal oils; and in describing them it will not be out of place to include a further account of the coal oil manufacture, which since the publication in this work of the article COAL PRODUCTS, containing a short notice of it, has attained great importance in the United States. The extraction of oil from bituminous substances, as shales, coals, asphaltum, &c., is no new discovery. The first announcement of the discovery that oil might be thus procured is contained in the specification of a patent granted in England in 1694 to Martin Eele, Thomas Hancock, and William Portlock, for "a way to extract and make great quantities of pitch, tar, and oyle out of a sort of stone, of which there is a sufficient found within our dominions of England and Wales." The stone proved to be a bituminous shale; but no practical results appear to have followed the discovery and the patent. In 1716 the Messrs. Betton of Shrewsbury patented a process for extracting oil from the black, pitchy, flinty rock commonly found overlying the coal beds. This must have been the bituminous shales; and their method was to grind them to powder and subject the material to destructive distillation. The product was used only as a medicine, and was noticed as such in 1761 in Lewis's "Materia Medica," under the name of British or petroleum oil, "extracted by distillation from a hard bitumen or a kind of stone coal found in Shropshire and other parts of England." The substance and the method of procuring it received occasional notice in the scientific journals; the earliest paper of much interest containing an account of Dr. Clayton's experiments was published in the "Philosophical Transactions" of Jan. 1739. But it was about

20 years after this before any decided advance was made in adding to our knowledge of the products of the slow distillation of organic bodies. The character of the coal gas was understood, and how to obtain it by distilling bituminous substances at high temperatures; and some of the compounds of hydrogen and carbon, derivable from the liquid products of this distillation, were eliminated and described. But the products of the slow distillation were known only as oily fluids, possessing no interest except as empirical medicines, when Reichenbach of Moravia undertook to investigate their properties, and extended his researches to the great variety of products of the destructive distillation at high and low temperatures of organic bodies, of animal as well as vegetable nature. The great number of new substances which he thus discovered, together with the promise that several among them might be applied to useful purposes, gave great interest to the accounts of his investigations which appeared in the scientific journals of Germany in 1830 and 1831. He was the first to describe the substance paraffine, which he obtained from wood tar, and to notice the distinction between it and the similar substance naphthaline, which is derived from the liquid products of the rapid distillation of bituminous matters, as practised in making gas. The mixture of the several hydrocarbons, such as constitute the purified coal oils, he called eupion (Gr. εὖ, very, and πίων, fat). He recognized the qualities in these oils that rendered them in no respect inferior to the finest oils for burning in lamps to produce light, and observed that a cheap method of separating them from the tarry residues was alone required to bring them into extensive use for domestic purposes. These valuable contributions to science and art were published in different numbers of the *Journal für Chemie und Physik* of Schweigger-Seidel, of the *Neues Jahrbuch der Chemie und Physik*, and in Erdmann's *Journal für praktische Chemie*, for 1830-'31. They attracted the attention of scientific and practical chemists in other parts of Europe, some of whom in France particularly were already engaged in the extraction of the oils from bituminous substances, a patent for which had been granted in 1824 to MM. Chervau; and in 1832 Blum and Moneuse patented the application of these oils to illuminating purposes. The latter had a factory near Autun in the department of Saône-et-Loire for treating the bituminous shales of that district; and the chemist Laurent was at this time engaged in conducting the operations, who a year or two afterward was succeeded by Selligue. The papers published by these chemists, and especially the specifications of the patents taken out by the latter from 1834 to 1845, published in the *Brevets d'invention*, present full details of the operations, which they had already brought to such a state of perfection, that the subsequent improvements introduced consist merely in comparatively unimportant modifications of the apparatus employed. Up to the year 1861 no *treatise* upon the subject had appeared at all comparable to that in the specification of the patent of March 19, 1845 (*Brevets d'invention*, new series, iv. 90). Of this an English translation is recorded in the specification of the patent of Du Buisson, No. 10,726 of the English patent office. (See also a paper on the history of this manufacture by F. H. Storer, in the "American Journal of Science," vol. xxx. pp. 121 and 264, 1860.) In this specification, Selligue describes first the apparatus employed in the distillation, in one form of which he makes use of superheated steam. The products of the distillation are then enumerated, which are as follows: 1, a very limpid whitish volatile oil, almost without odor, useful as a solvent or for illumination in suitable lamps, and sometimes known as naphtha; 2, a straw-colored oil, somewhat volatile, of specific gravity 0.84 to 0.87, almost odorless, and suitable for burning in lamps in which the oil is kept at the same level, and which are provided with a double current of air, with a chimney, and proper burner; 3, a heavier oil adapted for lubricating machinery; 4, a red coloring matter extracted from the different varieties of the oils; 5, paraffine; 6, a grease for lubricating machinery, being evidently a mixture of paraffine in little oil; 7, a black pitch, the residue of the distillation, suitable for coating wood, metals, &c., for their preservation; 8, an alkaline soap prepared by treating the oil with alkalies; 9, sulphate of ammonia; 10, fertilizing mixtures prepared with the ammoniacal liquors; 11, sulphate of alumina. The crude oil obtained from his retorts, which were like those of the gas works, he treated either before or after its being redistilled with a quantity of acid (sulphuric, muriatic, or nitric), and caused the mixture to be thoroughly agitated. This operation being continued for some time, the tarry matters are partially freed from the oil, and on the mixture being left to repose they subside with the acid, so that the purified oil can be drawn off from the top, bringing with it but little of the acid. This is neutralized by addition of an alkali, as the lye of soap boilers, and after the mixture has been well agitated again, more tar and coloring matter subsides, from which the oils are separated by decanting again and redistilling. By a series of fractional distillations the several sorts of light oils are obtained in a pure state.—In England, and incidentally in the United States also, the establishment of the coal oil manufacture is due to the enterprise of James Young, Esq., of Glasgow. In 1847 his attention was directed to the extraction of a lubricating oil from petroleum, that exuded from a coal mine in Derbyshire; and having exhausted the supply of this, he next applied to the same purpose the Torbanehill mineral or Boghead cannel, a material which was first ascertained in 1850 to possess an unusual proportion of bitumen, and to be capable of affording large quan-

tities of gas. (See Coal.) Mr. Young found it still better adapted for the manufacture of oil, and succeeded so well in this enterprise that in the year 1854, as he testified in a lawsuit for establishing his patent, his production of oil amounted to about 8,000 gallons a week, which sold for 5*s.* a gallon. For the year the sales reached about £100,000, a large proportion of which was profit. Such success soon led others to undertake the same branch of manufacture, and coal oil works rapidly increased in England, and were introduced into the United States. The first factory of the kind in this country was that of the kerosene oil company, on Newtown creek, Long island, opposite the upper part of New York city, which went into operation in June, 1854. It was designed to work the Boghead cannel or other materials of similar character that might be brought to New York from New Brunswick or Nova Scotia, or from the western coal mines; and the operations were to be conducted under the patent of Mr. Young granted to him in this country, as well as in England, for the exclusive use of coal for this manufacture. His claim, however, was not recognized at other works of later date in the United States, and was never enforced. In 1856 the Breckenridge coal oil works at Cloverport, Ky., on the Ohio river, were producing oil from the cannel coal of the vicinity, which somewhat resembled the Boghead cannel in appearance and in its rich bituminous character; and the same year a factory was built in Perry co., Ohio. The cannel coals of this region proving to be well adapted for this application, several other factories were soon constructed, particularly in the vicinity of Newark, Licking co., Canfield, Mahoning co., and in Coshocton co.; and at the close of the year 1860 the total number in Ohio was probably not less than 25, the working capacity of which might average 300 gallons of light oils a day each. At the same time there were 6 or more factories in Kentucky; one in St. Louis, Mo.; 8 or 10 in Virginia, mostly in the Kanawha region, except a few near Wheeling; about 10 in western Pennsylvania; 5 in the environs of New York city; one at Hartford, Conn.; 4 in and about Boston; one in New Bedford; and one in Portland, Me. The coals employed in these works were found to differ greatly in their capacity of producing oil; and none of them were so valuable in this respect as the Boghead cannel. From this it was found possible to extract 130 gallons of crude oil, yielding about 75 gallons of refined oil, per ton; the usual product, however, is about 117 gallons of crude and 60 of rectified oil. The maximum yield of the Albert coal of New Brunswick is 110 gallons of crude and about 75 of rectified oil; of the Breckenridge coal and the cannel coals of Virginia from 90 to 100 gallons of crude and 50 to 60 of rectified oil; of those of Ohio from 55 to 87 gallons of crude oil; and of those of Beaver co., Penn., from 45 to 55 gallons crude oil.—The processes pursued in the different works are essentially the same. The only distinctions of importance are in the forms of the apparatus, and particularly in the retorts. The common form in use for some time was that of the gas retorts—long cast iron boxes, with an opening at the end, that projected from the furnace in which they were set, and shaped in their section like the letter ⌓. Others were made of cylindrical form, were set upright in the furnace, made to be charged at the top and discharged at the bottom, and furnished with exit pipes for the volatile products either at the top or at different heights. Earthenware retorts have been substituted in some works for those of cast iron, as in the manufacture of gas. In the use of all of them a loss results from the unequal degree in which portions of the charge are heated, a part being rapidly overheated so as to produce gaseous matters, while other parts are acquiring the heat necessary for the generation of the oily products. To correct this defect a form of retort was invented in France in the early periods of the manufacture, called the revolving retort. This was a cast iron cylinder, which as now used is about 8 feet long and 6 feet in diameter, suspended in the furnace upon an axle in the centre of each end and made by machinery to turn slowly over while the charge is heating, usually about two revolutions in a minute. The volatile products find their way out to the condensers through the axle at one end, which is made hollow for this purpose. The charge is introduced through a man hole in the front end. For a large retort it may amount to 2½ tons of coal. This is distilled in 6 hours, and the carbonaceous residue and ash being drawn out a new charge is immediately introduced. By keeping the retort at a temperature below redness, the operation goes on rapidly with great uniformity and with the largest production of oil. Such retorts, however, are costly to construct, are more liable to get out of order than the fixed retorts, and it is also objected to them that the coal is more or less ground to powder, which in the condition of dust is carried off by the vapors, obstructing the condensers and adding to the cost of the purification. Methods of distillation are also in use by which an external fire is dispensed with, and the heat required for the expulsion of the volatile matters is produced by the combustion of a portion of the material, as in the process of charring wood for charcoal, and coal in pits and kilns for coke. Near Wheeling, Va., this plan is in operation, the coal being collected in pits to the amount of 100 tons at a charge, and covered with earth. The fire is started at one end, and a draught through the piles is produced by the exhausting action of a jet of steam applied in the outlet pipe at the opposite end. A draught is also produced at other places where this method is adopted by means of a tall chimney, between which and the pits the vapors pass through the condensers. An ingenious form of kiln was invented and introduced in 1859 at the kerosene oil works, by Mr. Luther Atwood. This is of circular form, resembling a lime kiln 20 feet high and 12 feet in diameter inside, open at the top, and of the capacity of over 25 tons of material. It is built of common brick and lined with fire brick. The charge of Boghead cannel being introduced, it is covered with about 4 tons of Cumberland coal and a quantity of pine wood. This is then set on fire, and at the same time a jet of steam is let into the eduction pipe which proceeds from the bottom of the kiln. A downward draught is thus produced, which is regulated and controlled by attention to the steam jet. The process is thus conducted as slowly or rapidly, with as much or little heat, as may be required, and most of this is produced at the expense of the cheaper Cumberland coal, in the combustion of which the oxygen of the air is consumed, so that little of it reaches and wastes the cannel below. About 4 days are required for completing the distillation. At the end of this time the charge has settled down, leaving in the bottom some unconsumed coal and incombustible ashy residuum. The kerosene company have 18 of these kilns at their works, and one beside of the capacity of 100 tons. The vapors from the retorts or kilns are conducted first into condensers, of which various forms are in use. Those of the kerosene oil company (to whose works the following description is more particularly applicable) are tall cylinders of boiler-plate iron, standing several of them together. Through these the vapors pass in succession, and as they are condensed the liquid products trickle down their sides, and are thence conducted into vats made of iron and set in the ground, while the gases escape from a chimney connected with the last of the condensers. Being inflammable like the coal gas, they may be applied to similar purposes, or they may be conducted into gasholders and burned under the stills for fuel. In the vats a partial separation takes place of oil and water, the former rising to the surface and flowing over into a conduit leading to a large reservoir in the ground of the capacity of about 40,000 gallons. The water settling beneath the oil would soon fill the vat, but for an ingenious arrangement, by which it is also continually discharged. This is a bent pipe with a long and short limb like a siphon, but used like a siphon inverted. It is put over the edge of the vat, the long limb inside reaching near the bottom, and the short one terminating outside a little below the level of the surface of the oil. The pipe being once filled, the water continues to flow up through it, and is received into the second vat, where, as it brings some oil with it, the same method of separation is repeated, and so it may be through several others. The liquid is finally collected into a large cistern, and upon the surface some oil still collects, which is saved by occasional skimming. From this cistern the waters with the ammoniacal products of the distillation are allowed to escape.—The crude oil collected in the great reservoir is like the natural petroleum, and the subsequent treatment of purification is the same for both. It is pumped out into the first set of stills, which at the works referred to are 18 in number, each one of the capacity of 1,500 gallons. They are made of cast or boiler-plate iron, with bottoms of cast iron 2 inches thick. Even this great thickness does not insure their stability, the iron soon becoming warped and finally cracking from the effects of the heat. The fires beneath them are of anthracite and of a remarkably dense coke, which in the distillation accumulates on the bottom of the still, the carbonaceous particles separating from the oil and forming an incrustation of 8 or 10 inches in thickness. The contents of the still are worked off in 24 hours, the temperature gradually rising up to 600° or 800° F. From the head of the still the vapors pass through the worm of the condenser, which, in the latter part of the distillation, is not allowed to cool down sufficiently for the paraffine to condense in it, as this might by causing obstruction endanger the explosion of the still itself; but by proper regulation of the fire and condenser a steady flow of the oil goes on from the end of the worm. The quantity obtained is within 10 or 12 per cent. of that introduced into the stills; and though freed of this amount of impurities, the oil is still of a greenish hue, and retains more or less of its disagreeable odor. The next process is the chemical treatment with sulphuric acid. The oil is transferred to large cylindrical cisterns, called agitators, of the capacity of 2,000 gallons each, and 5 or 6 per cent. of sulphuric acid being added to it, the mixture is swept rapidly round by the revolution of stirrers in the tub moved by machinery. This having been kept up for some time and the mixture being left some hours to repose, a considerable part of the impurities settle with the acid to the bottom, from which they are drawn off, leaving the partially purified oil in the upper part of the cisterns with some acid and impurities still adhering to it. These are mostly removed by agitating again with water, and again after a repose of some hours drawing off the matters that have collected in the bottom. After this a strong lye of potash or of soda is introduced into the oil in the agitator, and the stirring is repeated with this; and the sediments being drawn off the washing is repeated, when the oil is ready for the second set of stills. This method of purification, called the "cold" treatment, may be advantageously varied by heating the oils. The second stills are of the same number and capacity as the first set. The first product of this distillation is a very light oil which, if at first somewhat discolored, is soon succeeded by a limpid oil that continues with little variation, except that it gradually becomes heavier. This is the merchantable illuminating oil, and includes all that portion of the distillate below the specific gravity of 0.820. Its proportion is very variable in the different oils, in some of the best natural oils amounting to 80 or even 90 per cent., and in others not exceeding 30 per cent. The products which succeed this are the heavy oils for lubricating, which pass into the last product of dark-colored heavy oils containing the paraffine. The heavy oils may be made to yield, by means of fractional distillations, the last portions of the light oils they still contain, and the heaviest portions may then be made to give up a considerable part of the paraffine by leaving the liquid in tanks exposed to a temperature as cold as may be. The paraffine condenses in bright silvery scales, and is recovered by drawing off the oil and then subjecting it to heavy pressure. It is purified by successive applications of sulphuric acid, hot water, and alkalies. From the agitators there finally proceeds a residuum of tarry matters mixed with those portions of the chemical ingredients that were introduced; these, and the alkaline impurities from the stills, are allowed to run to waste, the alkalies only having been economically recovered at one or two establishments. The illuminating oils may be almost entirely freed from the odor they possess by standing several days over alkaline solutions in shallow cisterns; and by exposure to light in open vessels the color they retain is also partially removed; but although the perfectly clear and colorless oils are greatly preferred in the market, even at 75 cents per gallon when the oils of a slightly yellow color will hardly sell at 60 cents, the latter in reality possess a greater illuminating power and are consequently worth more to the consumer than the perfectly limpid oils.—Of the materials now employed for lamps, the coal oils, on the considerations of safety, economy, and the brilliancy of the light they afford, are to be preferred to all others. The chief obstacle at present to their general use is the necessity of employing a chimney to effect a thorough combustion of the vapors as they pass from the wick, and thus insure a flame free from smoke. Encumbered with this appendage, the lamps themselves are more expensive than those designed for other fuel, and this with the inconvenience attending their use has prevented many from adopting this mode of illumination.

PETRONIUS ARBITER, the name prefixed to the fragments of a Latin composition entitled *Petronii Arbitri Satyricon*, which consists of a prose narrative interspersed with a few poems. It describes the adventures of several young debauchees in the south of Italy, particularly Naples and its environs. Parts of the dialogues and descriptions are of an obscene character, although the style is deemed elegant and the language classical. The most important section is called the "Supper of Trimalchio," and gives an account of the banquet of a wealthy gourmand; next to this in interest is the tale of the "Ephesian Matron." The longest section in verse is a poem on the civil war, amounting to 295 hexameter lines. Scholars have variously placed the date of the author from the last years of Augustus to the reign of Constantine the Great. By many it has been maintained that he was the Petronius referred to by Tacitus (*Ann.* xvi. 18, 19) as the most elegant voluptuary of the days of Nero, the *arbiter elegantiæ* of that monarch, and director of his pleasures. His life being threatened by the jealousy of Tigellinus, he opened his veins, and, occasionally checking the flow of blood by bandages, sank so gradually that his death seemed to be the result of natural causes. In his last moments he is said to have sent to Nero a sealed document, giving an account of the excesses and debaucheries of the emperor, and taunting him with them. The first separate edition of Petronius Arbiter was printed at Venice in 1499. The best is that of Burmann (2 vols. 4to., Amsterdam, 1743). There are English translations in Bohn's "Classical Library."

PETROPAVLOVSK. I. A town of Asiatic Russia, situated on the bay of Awatska, on the S. E. coast of the peninsula of Kamtchatka, in lat. 53° 1′ N., long. 158° 43′ E.; pop. about 1,000. It is the capital and principal military station of the province of Kamtchatka. The harbor is good, has a lighthouse, and is defended by 2 forts. A few vegetables are raised; but fish is the great article of produce, and is dried in large quantities for exportation. A British squadron bombarded Petropavlovsk in Sept. 1854. II. A town of Russia in Asia, in the government of Tobolsk, situated on the river Ishim, 190 m. W. from Omsk, on the great post road of Siberia; pop. about 4,000. It is an important military post. A large trade is carried on with other parts of Siberia, Toorkistan, and the W. part of China, Petropavlovsk being a station for the caravans from Bokhara, Khiva, and the Kirghis steppe, and one of the principal commercial entrepots between European Russia and central Asia.

PETROZAVODSK, a fortified town of Russia, capital of the government of Olonetz, situated on the Lossolenka, where it falls into Lake Onega, 192 m. N. E. of St. Petersburg; pop. about 8,000. It contains 6 churches, schools, an imperial cannon foundery, 2 extensive docks for lake vessels, and manufactories. Three thousand tons of iron, considered the best in Europe, are annually produced here.

PETRUS LOMBARDUS. See LOMBARD, PETER.

PETTIS, a central co. of Mo., drained by La Mine river and branches; area, about 600 sq. m.; pop. in 1860, 9,492, of whom 1,982 were slaves. It has an undulating surface, with extensive prairies and forests of timber, and the soil is fertile. The productions in 1850 were 519,439 bushels of Indian corn, 89,915 of oats, 20,000 of wheat, 1,244 tons of hay, 25,516 lbs. of wool, and 61,898 of butter. There were 5 grist mills, 8 saw mills, 2 tanneries, 15 churches, and 700 pupils attending public schools. Capital, Georgetown.

PEWEE, a name given to several species of American flycatchers of the sub-family *tyranninæ*. The common pewee, or Phœbe bird (*sayornis fuscus*, Bonap.), is 7 inches long and 9⅓ in alar extent; the general color of the plumage is dull olive brown above, darkest on the head, and yellowish white below; quills brown, most of the wing feathers edged with dull white; tail forked, the outer edge of the lateral feather dull white; bill and feet black. This lively species is found throughout eastern North America, from Newfoundland to Florida. In the middle states it arrives from the south early in April, and gets out a first brood by the middle of May, and a second by the beginning of August; it leaves again for the south in October, migrating by night. The nest resembles that of the barn swallow, being made of mud, grasses, and moss, lined with softer materials, and attached to a rock, wall, or rafter; they repair the same nest year after year; the eggs, 4 to 6, are white, with a few reddish spots at the larger end; the young are hatched out on the 13th day, and leave the nest in 16 more; the parents show great affection for them, snapping the bill and darting boldly toward all intruders. Its flight is rapid, with frequent sailings; it is fond of vibrating the tail, erecting the crest, and making a tremulous motion with the wings; it feeds on insects, which it takes with great dexterity and rapidity on the wing, swallowing them whole, and ejecting the hard parts like the swallows and goatsuckers.—The wood pewee (*contopus virens*, Cab.) is 6⅓ inches long, and 10¾ in extent of wings; the general color above is brownish olive, brownish black on the head; 2 pale grayish bands across the wings; a narrow white circle around the eyes; greenish yellow below, with a grayish tinge on the throat and breast. It is fond of the most gloomy forests, but is sometimes seen in shady orchards, and in the autumn near the edges of still ponds surrounded by woods. The flight is swift, with sudden sweeps in pursuit of its insect prey; it seizes with certainty moths and other nocturnal insects when it is very dark; it feeds sometimes also on berries. Its notes are low, mellow, and sweetly melancholy when in its favorite haunts; its common name, like that of others of the sub-family, is derived from its utterance of the syllables "pe-wee," singly or repeated, as Audubon says like what one might imagine to be the prolonged "last sighs of a despondent lover." It reaches the middle states about the 10th of May, going as far north as New Brunswick, south to New Granada, and west as far as the high central plains. The nest is delicate in form and structure, covered by lichens, and so apparently a part of the branch to which it is attached as to be detected with difficulty; the eggs are 4 or 5, light yellowish, with reddish spots at the larger end; in the middle states 2 broods are raised in a season; it boldly attacks man, beast, or bird approaching its nest.—Many other dark-colored flycatchers are called "pewee" in various parts of the country; as, for instance, the short-legged pewee (*C. Richardsonii*, Cab.), much resembling the last species, and found on the western coast of North America.

PEWIT, a name applied to the lapwing plover (*vanellus cristatus*, Meyer), and sometimes in Great Britain to the black-headed gull (*larus ridibundus*, Linn.), and in America to the pewee.

PEWTER, an alloy variously composed of different metals. Tin and lead are commonly used, but in no regular proportions. To these other metals are occasionally added, as a little copper, which makes the alloy harder and sonorous; antimony to harden and give a silvery lustre; and zinc, which is said to cleanse the alloy. The last is sometimes introduced in a strip of half zinc and half tin, which is used to stir the melted metals; and sometimes a lump of zinc is allowed to float upon the surface during the casting, its fumes probably protecting the metals beneath from the oxidizing action of the air. The inferior sorts of pewter contain the most lead, some having full half their weight of this metal; the alloy is dull and soft and of bluish shade. The best pewters contain only ⅓ or ⅙ of lead, the remainder being tin; they appear like tin, and are used for plates and dishes. A pewter of 82 parts tin and 18 lead is sanctioned by the French government for vessels to contain wine or vinegar. This has a specific gravity of 7.764; a greater density indicates a larger proportion of lead. Pewter has been largely employed for domestic utensils, as plates, mugs, spoons, &c.; and it is used by lapidaries for polishers and laps. Sheets of it serve for cheap engraving, as of music, the notes being stamped upon the alloy instead of the more costly method of engraving with the burin.

PEYRONNET, CHARLES IGNACE, comte de, a French statesman, born in Bordeaux in 1775, died in Jan. 1854. His father, an attorney of the parliament of Guienne, had been ennobled, and suffered death by the guillotine during the revolution. Charles withdrew from France, but returned after the 9th Thermidor, and in 1796 was admitted to the bar in his native city. He was better known by his licentious life and many duels than his standing in the profession. In 1814 he figured among the royalist partisans who called in the English and proclaimed the Bourbons. In 1815, being a captain in the national guard, he evinced respect and devotion to the duchess of Angoulême, on her flight to England; and his conduct was rewarded on the second restoration by his appointment as president of the civil tribunal of Bordeaux. In 1818 he was promoted to the post of attorney-general at Bourges, was elected from that city to the chamber of deputies, and was chosen in 1820 to assist in the prosecution before the court of peers of the imperialist conspirators, where he distinguished himself so much as to be rewarded the next year with the portfolio of minister of justice in the Villèle cabinet. During his 7 years' tenure of office, he proved an uncompromising supporter, if not the prime mover, of all the reactionary measures proposed or adopted. In 1822 he proposed the law for the restriction of the freedom of the press; in 1823 advocated the armed intervention in Spain; in 1824 procured the reëstablishment of the censorship; in 1825 caused the adoption of the law against sacrilege; in 1826 attempted to have the right of primogeniture restored; and in 1827 tried to restrict the press still more, dissolved the national guard, and altered the jury law. The elections of 1828 obliged Charles X. to dismiss the Villèle cabinet; but in 1830 Peyronnet became minister of the interior under the premiership of Polignac. He signed the royal ordinances of July 25, which brought about the revolution, although he is said to have disapproved of them. After the outbreak he was arrested at Tours when trying to escape, was taken to Vincennes, arraigned with his colleagues before the court of peers, sentenced to perpetual imprisonment, and incarcerated in the castle of Ham, where he wrote a *Histoire des Francs* (2 vols. 8vo., 1835). Released after 6 years, he retired to private life.

PFEFFEL, Gottlieb Konrad, a German poet and fabulist, born in Colmar, June 28, 1736, died there, May 1, 1809. At the university of Halle he pursued the study of law, and while there in 1757 lost his sight, which he never regained. In 1773, with the assent of the king of France, he founded an academy for the purpose of teaching the Protestant youth in Colmar. This the French revolution broke up, and henceforth he applied himself to literary occupations. In 1803 he became president of the newly founded evangelical consistory in Colmar. His "Poetic Essays" fill 10 volumes (new ed., Tübingen, 1802–'10), and his "Prose Essays" the same number (Tübingen, 1810–'13).

PFEIFFER, Ida, a German traveller, born in Vienna in 1795, died there, Oct. 27, 1858. Her maiden name was Reyer. From childhood she had a great curiosity to see foreign countries, but it was not until she had reached the age of 47 that, her husband being dead and her two sons established in life, she was enabled, with a small sum saved from her narrow income during 20 years, to undertake a journey to Palestine. She left Vienna in March, 1842, and after visiting Constantinople, Broussa, Beyrout, the chief places of the Holy Land, Egypt, the Red sea, Malta, Sicily, Naples, and Rome, reached home again in December of the same year, and published her journal under the title of a "Journey of a Vienna Woman in the Holy Land" (2 vols. 12mo., 1844). A tour through Norway, Lapland, and Iceland in 1845 afforded material for her narrative of a "Journey to the North of Scandinavia and Iceland" (2 vols. 12mo., Pesth, 1846). On June 29, 1846, she sailed from Hamburg in a Danish brig on a voyage round the world, accompanied by Count Berchthold, from whom, however, she subsequently parted company, finding that his strength and spirits were not equal to her own. They landed at Rio de Janeiro in September, intending to cross the South American continent to the Pacific. This plan, however, they could not carry out. In one of their excursions into the interior they were attacked by a negro armed with a lasso and long knife, but defended themselves with two parasols and a jack-knife until assistance arrived. Both travellers were wounded, but Madame Pfeiffer was soon recovered sufficiently to visit, with a single guide, the Puri Indians, whom she joined in a great parrot and monkey hunt. Taking ship again from Rio de Janeiro to Valparaiso, she made a short stay in Chili, and then went in a Dutch vessel to Macao, touching on the way at Tahiti, where she spent a fortnight. From China she went to Calcutta, and thence overland to Bombay, performing about half of the journey, for the sake of economy, in an ox cart. An English steamer conveyed her from Bombay to Muscat, Bushire, and Bassorah, whence she sailed up the Tigris to Bagdad, and after a little more than a month's residence there proceeded by caravan to Mosul, and thence to Ooroomeeyah in Persia, where she arrived after a journey of extraordinary privation and danger. In a similar manner she reached Tabriz and Erivan, travelled thence to Redout-Kalé on the E. shore of the Black sea, and there taking the steamer visited Kertch, Sebastopol, Odessa, Constantinople, Smyrna, Athens, and Trieste, and reached Vienna Nov. 4, 1848, having made the circuit of the globe in 2 years and 4 months. Her journal was published under the title of "A Woman's Journey round the World" (3 vols. 12mo., Vienna, 1850). In April, 1851, the Austrian government having given her $500 toward the expenses of another voyage, she visited London, and sailed from the Thames in May for the Cape of Good Hope, hoping to penetrate into the interior of Africa and reach Lake Ngami; but finding the cost of such an expedition beyond her means, she went to Borneo, Java, Sumatra, Celebes, Banda, Ceram, and Ternate, fearlessly making long excursions among the dangerous tribes of the interior of some of these islands; and in July, 1853, she accepted a free passage which was offered her by an American captain from Batavia to San Francisco. She spent 3½ months in California, and then proceeded by steamer to Panama and Callao, crossed the Andes to the sources of the Amazon, returned to Panama, traversed the isthmus, sailed for New Orleans, ascended the Mississippi as far as the falls of St. Anthony, visited the great lakes and the falls of Niagara, the St. Lawrence, Montreal, Quebec, Lake Champlain, the Hudson river, and New York, and on Nov. 10, 1854, took the steamer to Liverpool. She passed a few months of the following year with one of her sons at St. Michael, one of the Azores, and then returned to Vienna, where her "Second Voyage round the World" appeared in 1856. Her last expedition was to the island of Madagascar, where she arrived in 1857, in company with a Frenchman who was soon arrested for a conspiracy to dethrone the queen, and ordered with his companion to depart from the island. Madame Pfeiffer returned home with a fever which ultimately caused her death. Her books have been translated into English and widely read. The haste with which her journeys were prosecuted renders them of little use as works of information, and they owe their chief interest to the remarkable circumstances in which they originated, and as records of womanly courage and perseverance under almost insuperable difficulties. Madame Pfeiffer was generally unaccompanied except by a hired guide, and ignorant of the languages of the people whom she visited. Her means were extremely narrow, and she was greatly indebted to the liberality of the English and Dutch colonial governments, and the proprietors of railroad and steamboat lines in the United States.

PFEIFFER, Louis Georg Karl, a German naturalist and physician, born in Cassel, July 4, 1805. He served as a surgeon in the Polish patriot army in 1831, and then devoted his attention to the study of natural history, travelled through a part of the Netherlands and Germany, and in 1838 visited Cuba. He has written extensively on subjects of natural history.

PFISTER, Albrecht, a printer of the 15th century, born about 1420, died about 1470. He was a card painter in Bamberg, but about 1455 began to print with movable types. It is doubtful whether he hit upon the invention independently, or learned it as an assistant of Gutenberg. The types of Pfister, although they have some similarity to Gutenberg's, are still peculiar. He began with the printing of school and prayer books, and fragments of Latin grammars of his work have lasted to our time. Among his productions were indulgences printed with metal types of the years 1454 and 1455, an almanac of 1457, and a *Biblia Pauperum*. His great work, however, is the Latin 36-line Bible in 3 vols. folio, and consisting of 881 leaves.

PFIZER, Gustav, a German lyric poet and critic, born in Stuttgart, July 29, 1807. He was educated at the gymnasium of his native place, studied in 1825–'30 at Tübingen, and in 1846 was made professor in the Stuttgart gymnasium. He first attracted attention by the publication of a volume of poems (Stuttgart, 1831). A second volume appeared in 1835. He also wrote "The Life of Martin Luther" (1836); a larger poem, entitled "The Foreigner and the German, Æneas Sylvius Piccolomini and Gregory of Heimburg, Historico-Poetic Forms of the 15th Century" (1844); and "History of Alexander the Great for the Use of Youth" (1847). He has been connected with various literary journals, and has written critical essays on Uhland, Rückert, and Heine.

PHÆDO, or Phædon, a Greek philosopher who flourished about the beginning of the 4th century B. C. He was a native of Elis and of noble birth, but, becoming a prisoner of war about 400 B. C., was brought to Athens and sold as a slave. He obtained his release through the efforts of Socrates, and was thereafter one of the most devoted adherents of that philosopher. Plato introduces him as the principal interlocutor in his dialogue on the death of Socrates. Phædo finally returned to Elis, and became the founder of the Elean school of philosophy.

PHÆDRA, in Greek legendary history, the wife of Theseus and daughter of Minos, king of Crete, and of Pasiphaë, and sister of Ariadne. Her stepson, Hippolytus, with whom she had fallen in love, refusing to gratify her passion, she accused him to his father of an attempt upon her honor. Theseus hereupon cursed his son, and asked Neptune to destroy him, which prayer the god complied with. When the innocence of Hippolytus became known, Phædra hanged herself, or according to some was put to death by her husband. The story of Phædra was the subject of tragedies by Sophocles and Euripides, now lost. Racine also wrote a tragedy on it.

PHÆDRUS, a Latin fabulist of the Augustan age. He was originally a slave, and was brought from Thrace or Macedonia to Rome, where he mastered the Latin language, and was freed by Augustus, who patronized him. He wrote 97 fables in iambic verse distributed in 5 books, and states in the prologue to the first book that he has simply turned the matter of Æsop's fables into poetry. In many cases, however, he has borrowed nothing from his model, as he refers to historical events of a later period. With the exception of a probable allusion by Martial in one of his epigrams (iii. 20), Phædrus is first mentioned by Avienus. The manuscripts of his fables are rare. The first edition was printed by P. Pithow (12mo., 1596), from a manuscript called the Rosamboanus, from the name of its owner, and supposed to date from the 10th century. The latest and only critical edition is that of J. C. Orelli (8vo., Zürich, 1831). Perotti, archbishop of Manfredonia, in the middle of the 15th century, made a collection of fables from Phædrus, Avienus, and others, among which were 32 not included in the usual editions of Phædrus; they were first published at Naples in 1809 by Cassiti, as a 6th book of Phædrus, but their genuineness has been much doubted.

PHAËTON, or Phaëthon (Gr. Φαεθων, the shining), in Greek mythology, the son of Helios (the sun) and the Oceanid Clymene. To satisfy those who doubted whether the sun was his father, he obtained from Helios an imprudent promise that he would grant him any favor he asked, and thereupon demanded permission to drive his chariot across the heavens. The celestial horses, despising their weak driver, turned out of their path, blackening the Ethiopians to the left by the near approach of the sun: and when the chariot went over to the right, so near to the earth as almost to set it on fire, Jupiter killed Phaëton with a thunderbolt and hurled him into the Eridanus (Po). His sisters, the Heliades, who found him lifeless, were changed into poplars and their tears into amber.

PHALANGER, a genus of marsupial mammals, the type of the family of *phalangistidæ*, so called from having the 2d and 3d toes of the hind foot united in a common integument. They are expert climbers, dwelling upon trees, and eating leaves, buds, fruits, and occasionally small birds, mammals, and insects; they keep concealed during the day on the branches or in the hollows of trees, quitting their hiding places at twilight; they are rather sluggish in their movements, except such as are provided with a flying membrane. The head is moderate, the face short, the upper lip cleft, and the muffle naked; limbs equal in length, all 5-toed, the anterior with compressed and curved claws, the posterior with the inner toe large, nailless, at right angles and opposable to the rest; the tail long, and generally prehensile; the pouch well developed; the eyes large; the stomach simple, and the cæcum largely developed. Of the genera composing this family, *phascolarctos* (De Blainv.) has been noticed under KOALA; the others are *phalangista* (Cuv.) and *petaurus* (Shaw).—In *phalangista* the teeth are: incisors $\frac{6}{2}$, canines $\frac{1-1}{0-0}$, premolars $\frac{2-2}{1-1}$, true molars $\frac{4-4}{4-4}$; the anterior upper pair of incisors are larger and longer than the rest, and the large lower incisors are nearly horizontal; the small teeth between the incisors and molars are not constant even on both sides of the jaws of the same individual, but in most the true molars are $\frac{4-4}{4-4}$; the tail is prehensile. The genus has been subdivided into 4 sub-genera. In the sub-genus *cuscus* the basal portion only of the tail is covered with hair; the ears short, almost hidden by the fur; eyes with vertical pupil; the fur is dense and rather woolly, and the apical part of the tail bare, with numerous fleshy tubercles. They are about the size of a domestic cat, and are confined to the islands of the Indian and Australian archipelagos. The ursine phalanger (*P.* [*C.*] *ursina*, Temm.) is of a general black color, freckled with yellow, under parts dirty yellow, and iris orange red; it is about 20 inches to the root of the tail, the latter being 19; they live in thick woods; the very fat flesh of this, as of other species, is much relished by the natives, and the teeth are used as ornaments; some of the species emit a fetid odor from the anal glands. In the sub-genus *trichosurus* the tail is densely clothed with fur, with the exception of a part of the under surface; ears distinct and usually long; they inhabit Australia; the fur is longer and looser than in the northern islands. The vulpine phalanger (*P.* [*T.*] *vulpina*, Desm.) is of a general grayish color, yellowish white below, with the muzzle and chin blackish, the feet tinged with brown, the tail bushy and black except at the base, and an oblong rusty patch on the chest; it is as large as a cat, with long, pointed, fox-like ears and nose, and numerous long black moustaches; in captivity it usually sleeps in the daytime, and takes its food between the hands like a squirrel; the prehensile tail assists it in climbing. In the sub-genus *pseudochirus*, the 2 inner toes of the fore foot are separated from and opposable to the other 3; the tail is covered with short hairs except at the tip; the ears short and round. Cook's phalanger (*P.* [*Ps.*] *Cookii*, Desm.) has long and soft fur, gray above and yellowish white below, with the sides and outer surface of limbs tinged with bright rusty; it is about 2 feet long, of which the tail is 1 foot; it inhabits New South Wales. In the sub-genus *dromicia* the ears are moderate and nearly naked, the nails small, and the tail clothed with small hairs, but naked at the end beneath; they resemble dormice in size, appearance, and some of their habits. The dormouse phalanger (*P.* [*D.*] *nana*, Geoffr.) has a very soft fur, of an ashy gray above tinged with pale reddish brown; under parts white, with rusty yellow shade on the chest; it inhabits Tasmania, and is 7½ inches long, of which the tail is one half. These are lively at night, sluggish by day, fat, feeding on nuts and similar substances, which they hold between the fore paws; they are harmless and gentle, but not affectionate; they are very fond of the blossoms of the *Banksia;* they hibernate in winter, like, but not to the same degree as, the dormouse. Specimens of these, and of several other species, have been seen living at the London zoological gardens.—The genus *petaurus* includes the flying phalangers, which have a membrane extended from the fore to the hind legs; the tail is very long, and well clothed with hair; they resemble flying squirrels in appearance and habits. The flying phalanger (*P. taguanoides*, Desm.) has broad, short, and rounded ears, densely hairy externally; the membrane extends to the elbow; the tail is cylindrical, longer than the head and body; fur long and soft; general color above brownish black, pencilled with whitish on the flanks, the under parts impure white, and the tail black; the length of the body is 20, and of the tail 22 inches. It inhabits New South Wales, is nocturnal, and feeds on flowers of gum trees, and on insects and honey contained therein; it is an expert climber, and rarely descends to the ground. Some of the smaller species, as the sugar or Norfolk island flying squirrel (*P. sciureus*, Desm.), are hunted for their fur, which is used for the same purposes as chinchilla. In flying powers they are equal to the flying squirrels. For other genera and species, and full details, the reader is referred to vol. i. of Waterhouse's "Natural History of the Mammalia."

PHALANX. See INFANTRY, vol. ix. p. 512.

PHALARIS, tyrant of Agrigentum in Sicily, probably from 570 to 555 B. C. He was a native of Agrigentum, or according to some of Astypalæa in the Ægæan sea, and acquired the supreme power by a stratagem. The early part of his reign was mild, and he is said to have been led to the career of cruelty and oppression for which his name has become notorious by the unwillingness of the people to submit to his authority. It is related that Perillus, an Athenian artist, constructed for him a brazen bull in which his victims were roasted, and the first sufferer by the machine was the maker himself. Athenæus speaks of his roasting children alive, and Aristotle says that he ate them. His misgovernment at last caused a popular outbreak, in which he was stoned to death. The stories of his cruelty are probably much exaggerated, and in the later Greek writers he appears as an admirer and patron of literature and philosophy. The "Epistles of Phalaris," which were first mentioned by Stobæus, and were first published at Venice in 1498, were long believed to be the productions of this tyrant; but their spuriousness was thoroughly exposed by Bentley. They are believed to be the work of a Greek writer of the age of the Cæsars. They have gone through several editions, and have been translated into English and other modern languages.

PHALAROPE, a family of wading birds, coming near the snipes, embracing the genus *phalaropus* (Briss.), subdivided into 3 by modern naturalists. In this family the bill is as long as or longer than the head, slender, straight, somewhat enlarged and depressed at the tip, which is curved and acute, the nostrils situated in the lengthened groove of the sides; wings long and pointed, the 1st and 2d quills equal and longest; tail short and rounded; tarsi as long as the middle toe, strong and compressed; toes long, the lateral united to the middle by a membrane running along the border of each, and more or less lobed as in the coot; hind toe moderate and elevated, and slightly margined with membrane; claws short and sharp; feathers of the breast compact and duck-like. These birds live in the northern regions, migrating south in severe winters; they are generally seen in pairs or small parties, swimming on the sea, lakes, ponds, and fresh water streams, usually near the margin, searching for floating seeds, aquatic insects, and small crustaceans; large beds of floating sea weed are their favorite resorts; they are excellent swimmers, though they do not dive, and high and rapid fliers; they lay 3 or 4 eggs in a tuft of grass in marshes. Wilson's or the gray phalarope (*P. Wilsonii*, Sab.; genus *steganopus*, Vieill.) is about 9½ inches long, with an alar extent of 17; the bill 1¼ inches, black; general color above ashy gray mixed with reddish; stripe behind eye reddish black; front of neck reddish brown; rump and upper tail coverts and under parts white; the young are cinereous above, mixed with dark brown, and ashy white below. It is found throughout the temperate regions of North and South America, on the Atlantic and Pacific coasts, and sometimes wanders to Europe; it is fond of wading as it searches for food, and is a lively and graceful bird; the marginal membrane of the toes is nearly even. The northern phalarope (*P. hyperboreus*, Temm.; genus *lobipes*, Cuv.) is about 7 inches long, with an alar extent of 14, and the bill 1 inch; the webs are scalloped at the joints. The general color above is brownish black, paler on the rump, and mixed with ferruginous on the back; head and neck behind sooty ash, and the latter encircled with a ring of bright ferruginous, with a stripe of the same on each side; tips of greater wing coverts white; sides ashy mixed with reddish, and under parts white; the young are brownish black above, many feathers with ashy or yellowish tips. This species is found in the temperate parts of North America, and is widely distributed over N. Europe and Asia; it is one of the handsomest and most graceful of the waders. They congregate in flocks, and are very shy; they breed in the north, both sexes incubating, the female having, it is said, a bare space on the abdomen where it comes in contact with the eggs; the eggs are 1¼ by ⅞ inch, of a buff color with dark reddish brown blotches. They have been seen on floating sea weed more than 100 miles from shore. The red phalarope (*P. fulicarius*, Bonap.) is 7½ inches long and 14 in alar extent; the bill is strong and flattened, widened at the end; the head above, throat, and back brownish black, on the last edged with pale ochrey yellow; wings and tail ashy brown; tips of greater wing coverts, and stripe on cheek, white; under parts deep brownish red, tinged with purplish on the abdomen; under wing coverts and axillaries white; bill greenish yellow; the young are light cinereous above, mixed with blackish brown on the head and wings, and white below. It is found in temperate America, Asia, and Europe, and is considered excellent eating in the autumn; the eggs are 1¼ by ⅞ inch, dull greenish yellow with blotches and dots of reddish brown.

PHANARIOTES. See FANARIOTES.

PHARAOH (Egypt. *Phrah*, "the sun"), the Egyptian word for king, and applied particularly to the native rulers of Egypt before the Persian and Macedonian conquests. The title denoted that the king was an emblem of the god of light, and derived his authority directly from heaven.

PHARISEES (Heb. *perushim*, those who are separated), a sect of the Jews, mentioned first by Josephus as an established religious party during the priesthood of Jonathan, about 150 B. C., but whose origin is unknown. Their name indicated their separation from the rest of the Jews by the assumed holiness of their lives and their strict observance of religious ceremonies. In the time of Christ they were divided into two schools, that of Hillel, who represented a moderate Pharisaism, and laid the foundation of the Talmud, and that of Shammai, who demanded more austere observance. The former finally prevailed. Josephus, who was himself a Pharisee, gives the following summary of their opinions: "The Pharisees have delivered to the people a great many observances by succession from their fathers, which are not written in the law of Moses; and for that reason it is that the Sadducees reject them, and say that we are to esteem those services to be obligatory which are in the written word, but are not to observe what are derived from the tradition of our forefathers. Hence great disputes. The Sadducees are able to persuade none but the rich, and have not the populace obsequious to them; but the Pharisees have the multitude on their side." ("Antiquities," xiii. 10, 5 and 6.) "The Pharisees live meanly and despise delicacies in diet; and they follow the conduct of reason, and what that prescribes to them as good, they do. They also pay respect to such as are in years, nor are they so bold as to contradict them in any thing which they have introduced; and when they determine that all things are done by fate, they do not take away from men the freedom of acting as they think fit, since their notion is that it hath pleased God to make a constitution of things whereby what he wills is done, but so that the will of man can act virtuously or viciously. They also believe that souls have an immortal vigor in them, and that under the earth there will be rewards or punishments, according as men have lived virtuously or viciously in this life. The latter are to be detained in an everlasting prison, but the former shall have power to revive and live again; on account of which doctrine they are able greatly to persuade the body of the people; and whatsoever is done about divine worship, prayers, and sacrifices, is performed according to their directions, insomuch that the cities gave great attestation to them on account of their entire virtuous conduct." ("Antiquities," xviii. 1, 3.) In the Gospels the Pharisees appear in a much less favorable light, being the most powerful and bitter enemies of the new religion. They are represented as proud, selfish, and hypocritical. In the Talmud several classes of Pharisees are mentioned, among which were the truncated Pharisees, who hardly lifted their feet from the ground, in order to seem absorbed in meditation; and the mortar Pharisees, who wore a cap shaped like a mortar, which would only allow them to look down, and gave them an appearance of profound contemplation, and at the same time kept them from seeing women.

PHARMACY (Gr. φαρμακον, a medicine or poison), the art of choosing, collecting, preserving, and preparing medicines. Pharmacy is intimately allied with several of the natural sciences, and its successful cultivation demands an extensive knowledge of chemistry, and familiarity with chemical manipulations and with the physical properties of medicines. Rules are given in works of pharmacy for the mode and time of collecting the various roots, herbs, leaves, seeds, &c., which enter into the materia medica; but these in this country are very rarely gathered by the apothecary; most of them are of foreign origin, and those of native growth are commonly obtained from persons who devote themselves specially to their cultivation and collection. In purchasing them care should be taken that seeds are perfectly ripe, that leaves and other parts have been gathered as recently as possible, are dry, free from impurities, of a fresh, lively color, and have their characteristic smell, taste, and general appearance strongly marked. In preserving medicines, volatile and deliquescent substances should be enclosed in bottles well stopped with ground glass stoppers, leaves and flowers in tin canisters or in boxes lined with tin, zinc, or lead; hydrocyanic acid and the salts of silver should be kept in the dark, &c. —In compounding and dispensing medicines, the apothecary uses the troy pound and its subdivisions, while for other purposes drugs are bought and sold by the avoirdupois pound, 9 of which are nearly equal to 11 pounds troy. The use of two different standards of weight is a fertile source of inconvenience and confusion, and this is further complicated by the use of a fluid measure for liquids. In this latter the wine pint, containing 28.875 cubic inches, is the standard, and this is divided into 16 fluid ounces, the fluid ounce into 8 fluid drachms, and the fluid drachm into 60 minims. A fluid ounce of water at 62° F. and 30° of the barometer weighs 455½ grains, being 18 grains more than an avoirdupois, and 24½ grains less than a troy ounce.—The various operations of pharmacy have for their object to render medicines more effective and less repugnant to the taste or the stomach. They are often powdered, and numerous devices are resorted to in order to convert refractory substances into powder or to render the powder sufficiently fine; sometimes it is precipitated from a solution by a chemical reagent. Insoluble earthy substances are levigated, that is, they are moistened with water or alcohol and then rubbed with a muller upon a hard flat stone; or they are elutriated, the powder being stirred up with a large quantity of water, and a little time being allowed for the coarser particles to settle, when the water is poured off and the finely divided powder which remains floating slowly subsides to the bottom. Camphor is powdered readily by adding to it a few drops of alcohol. Some substances require to be powdered while hot, others after having been previously well dried, &c.—Extracts are formed either by first expressing the juice of certain plants by means of a screw press, or by forming solutions of their active principles by means of alcohol, ether, or water, and then evaporating to a proper consistence by means of a carefully regulated heat, and if possible with the exclusion of air. Tinctures are solutions of the active principles of medicines in alcohol, proof spirits, or ether. The active principles of certain vegetable substances are often isolated from the inert matter with which they are naturally combined, and used either pure or united with an acid to increase their solubility; for example, quinine is obtained from cinchona bark, morphine from opium, strychnine from nux vomica, and atropine from belladonna leaves. Some pharmaceutic preparations have for their object the preservation of an unstable compound; the carbonate of iron is rapidly decomposed when exposed to the atmosphere, but when united with saccharine matter it remains unchanged for a length of time. Some preparations, as pills and mixtures, have for their object convenience of administration, or the disguising of nauseous taste or odor; other medicines are adapted to particular objects, as plasters, ointments, cerates, liniments, &c. Formulas for certain preparations of widely approved activity are received into the pharmacopœia, and thus become officinal, while extemporaneous compounds ordered by the physician are called magisterial.

PHARO. See Faro.

PHAROS, the ancient name of a small island lying off the coast of Egypt, 7 stadia from the ancient Alexandria, connected with the mainland by a mole, and famous for its lighthouse, which gave the name of Pharos to all structures of a similar kind. (See Alexandria, and Lighthouse.) The island became at length a suburb of Alexandria by means of a street running along the mole, and retained some importance even to the time of Julius Cæsar, but subsequently sank into its original condition of a fishing station.

PHARSALUS (now *Phersala*), a city of Thessaly, situated in Thessaliotis, on the left bank of the Enipeus, and at the foot of Mt. Narthacius. In history it is not spoken of until after the Persian wars. In 455 B. C. it was unsuccessfully besieged by the Athenian general Myronides, after his Bœotian expedition. Through Polydamas, a native ruler, it became subject to Jason, tyrant of Pheræ, and was for a time in the possession of Antiochus in his war against the Romans, but was taken by the consul Acilius Glabrio in 191. In the time of Pliny Pharsalus was a free state. The ancient city was nearly 4 miles in circuit, and situated upon an eminence which was 600 or 700 feet high, and on 3 sides was defended by precipices. "It is," says Leake, "one of the most important military positions in Greece, as standing at the entrance of the most direct and central of the passes which lead from the plains of Thessaly to the vale of the Spercheius and Thermopylæ."—Pharsalus is chiefly celebrated for the battle fought in its territory (called Pharsalia) on Aug. 9, 48 B. C., between Cæsar and Pompey. The army of the former, consisting of 21,000 foot and 1,000 horse, was posted on the plain between Pharsalus and the Enipeus; that of the latter, consisting of 45,000 foot and 7,000 horse, was drawn up opposite. Pompey expected with his body of cavalry to turn Cæsar's right wing, and thus gain the victory. The army of Cæsar advanced to the charge on a run, and when the engagement became general along the whole line, Pompey began the execution of his manœuvre; but after driving back the small body of horse opposed to them, his cavalry were unexpectedly assailed by 6 cohorts of infantry, which Cæsar, suspecting the design of the enemy, had stationed on the right as a reserve force. Pompey's cavalry were put to flight, and, the 6 cohorts turning his left wing, his troops gave way in every direction. He himself retired to the camp in great dejection, and after the rout became general he fled. His camp was stormed about the middle of the day, and the victory was rendered complete by the surrender of 4 legions, which Cæsar, who never gave any rest to a flying enemy, succeeded in taking prisoners about nightfall. This battle decided the fate of the Roman world.

PHASCOGALE, or Pouched Mouse, a genus of small marsupial mammals of the *dasyurus* family, inhabiting Australia and Tasmania. The dental formula is: incisors $\frac{8}{6}$, the two anterior in each jaw larger than the others, canines $\frac{1-1}{1-1}$, premolars $\frac{3-3}{3-3}$, true molars $\frac{4-4}{4-4}$, studded with prickly tubercles. All the feet are 5-toed, the inner one on the hind feet a small, nailless, prehensile thumb; tail either wholly clothed with short hairs, or with long and bushy ones on the apical portion; the females are sometimes destitute of a pouch, the young being protected only by the hair of the abdomen; mammæ 8, arranged in a circle. The cranial cavity and occipital opening are comparatively large, and the muscular ridges of the skull and the cervical spinous processes feebly developed; the muzzle pointed and moderately long, muffle naked, nostrils lateral, ears moderate, and limbs short; they are insectivorous, and climb trees in search of food. The largest species is the brush-tailed phascogale (*P. penicillata*, Temm.), about the size of a common rat, 18 inches long, of which the tail is one half; the fur is long and soft, gray pencilled with white, below white, the middle part of the head dusky, and the tail bushy, with long black hairs except on the basal third, where they are short and gray; it is widely distributed in Australia; it makes a nest in the hollows of trees, and is accused of attacking the poultry and plundering the stores of the settlers. The handsome-tailed phascogale (*P. calura*, Gould) is about 10¼ inches long, of which the tail is 5; it is ashy gray above, yellowish white below, with the base of the tail bright rust color and the apical half with long black hairs; it inhabits W. Australia. Several other species are described by Waterhouse ("Natural History of the Mammalia," vol. i.), in which the tail is uniformly clothed with short hairs; they are pretty and active animals, varying in length from 11 to 6 inches, of which the tail is one third.

PHAULCON. See Constantine Faulcon.

PHEASANT, an extensive family of gallinaceous birds, comprising the sub-families *pavoninæ* or peacocks, *gallinæ* or jungle fowls, *phasianinæ* or pheasants proper, *lophophorinæ* or monauls, and *meleagrinæ* or turkeys. Of these, the 1st and most of the 2d have been described; the 5th will be found under TURKEY; and only the 3d, 4th, and a part of the 2d will be noticed here. The family includes the handsomest of the rasorial birds, and is for the most part confined to Asia and its islands; the Guinea fowl, however, is African and the turkeys American; the latter, with the common fowl and the peacock, have been completely domesticated, and are distributed very generally over the globe. The head is rarely feathered all over, but more or less about the eyes and often a considerable part of the neck are bare, and furnished with crests, wattles, and combs of singular forms.—In the *phasianinæ* may be included the genera *phasianus* (Linn.), *thaumalea* (Wagl.), and *argus* (Temm.). In *phasianus* the bill is moderate, strong, vaulted and slightly arched at the tip, which overhangs the lower mandible; the nostrils in a lateral groove and partly closed by membrane; the wings short and rounded, the 4th and 5th quills the longest; tail lengthened, wedge-shaped, with each feather attenuated; tarsi robust, covered in front with divided scales, and in the males armed with a strong spur; toes strong, united at the base by a membrane, the hind toe short and elevated, and the claws stout and slightly curved. The few species described are naturally inhabitants of the mountainous regions of Asia, but some have been naturalized in temperate Europe; they frequent thick jungles, the sexes keeping separate except in the breeding season, when they form families of a single male and several females, each with their special locality, from which all intruders are expelled. They are rapid runners, and fly rapidly and noisily for short distances; the food consists of grains, seeds, bulbs, and insects, which they seek usually toward sunset; they roost in trees in the cold season; the eggs are 10 or 12, and are laid generally on the ground, with very little if any nest. The common pheasant (*P. Colchicus*, Linn.) is about 3 feet long, of which the tail is nearly one half; the male is bright rufous above, the head and neck blue with green and golden reflections, and variegated with black and white; the cheeks bare and red, the sides and lower parts purplish chestnut; tail with transverse black bands; the female is smaller, brownish gray, varied with reddish and dusky. This bird is supposed to have been introduced from the banks of the Phasis, a river of ancient Colchis, on the E. coast of the Black sea, whence its scientific name; it is generally distributed over S. Europe, but in the northern parts requires protection by stringent game laws to prevent its extinction; it could probably be introduced with advantage into the temperate parts of America. Its habits are much like those of the common fowl; it breeds in confinement, but is apt to neglect its eggs, which are therefore usually placed under a common hen; it will breed with the common and Guinea fowls, in the wild state with the ring-necked species, and, it is stated, also with the black grouse. A breed called the ring-necked pheasant has a white ring around the neck, and is either a mere variety, or a hybrid with the *P. torquatus* (Gmel.) of China. Pheasant shooting is a famous pastime in Europe, and great numbers are killed at *battues;* they are special favorites with poachers; the flesh is excellent. They are subject to an epidemic and often fatal disease in confinement, called the "gapes," caused by a nematoid strongyloid parasitic worm (*sclerostomum syngamus*, Dies.), which produces inflammatory swelling of the windpipe, and frequently suffocation; the best remedy is fumigation with tobacco carried to stupefaction. Other more beautiful species from Japan and northern Asia are Diard's pheasant (*P. versicolor*, Vieill.), of a general rich green color with golden and violet reflections, throat and fore neck bright blue, and back variegated with golden yellow, purple, and violet; Sömmering's pheasant (*P. Soemmeringii*, Temm.), of a rich reddish purple, with bronzy lustre, and each feather with brilliant edging; and Reeve's pheasant (*P. superbus*, Lath.), rich yellowish above, with white head, neck, and under parts, the middle of the latter being black; tail sometimes 4 feet long, grayish white with golden red edges and crescentic bars of brown and chestnut.—The genus *thaumalea* differs from the last only in having the head furnished with a crest of long slender feathers, and a kind of tippet of lengthened feathers around the back of the neck. The golden pheasant (*T. picta*, Wagl.) is perhaps the most gaudy of the family, the brilliancy and variety of its plumage being beyond description; it is, however, well known in aviaries and collections; the general color is golden yellow above, scarlet below, with yellow crest, green back, brown hood, and blue secondaries; it is about the size of the common pheasant, but the tail is longer; as usual in the family, the female has a plain brownish plumage. It is a hardy bird, a native of China, kept in domestication, and highly prized for the table. Lady Amherst's pheasant (*T. Amherstiæ*, Leadb.) has the top of the head, breast, back, and wings rich metallic green, the tippet and lower parts white, the former banded and tipped with green, and the tail variegated with brown, green, yellow, scarlet, and white.—In the genus *argus* the 7th and 8th quills of the wings are the longest, with the secondaries remarkably prolonged; the tail is long and compressed, with the 2 middle feathers much elongated; the tarsi long and slender, without spurs; head and neck covered only with scattered hairs. The argus pheasant (*A. giganteus*, Temm.) is about the size of a common fowl, but the 2 middle tail feathers are 3½ or 4 feet long; the under parts and lower neck are reddish brown spotted with yellow and black; the back ochrey yellow, with black and brown spots; tail deep chestnut with white spots surrounded by a black ring; secondaries about 3 feet long, brownish, but when spread adorned with beautiful ocellated spots like those in the peacock's tail; the female is dull chestnut red, varied with yellowish brown and black, without the development of the tail feathers and secondaries. It is found in the dense forests of Sumatra and the other large East Indian islands, where it lives in pairs; the long secondaries, which render flight difficult, are of great service to the bird when running, acting in the manner of sails; these feathers, with those of other brilliant gallinaceous birds, are exported from Batavia as ornaments for dresses, screens, fans, and similar objects. This bird does not thrive in confinement.—In the sub-family *gallinæ* should be mentioned here the genus *gallophasis* (Hodgs.) or *euplocamus* (Temm.), in which the wings are moderate and much rounded, with the 4th to the 7th quills nearly equal and longest, and the secondaries ample and broad; tail and its coverts ample, with compressed sides, arched or straight, and sometimes forked; tarsi long, strong, and armed with a large spur; the sides of the head bare, with wattles at the base of the lower mandible, and sometimes a crest. They inhabit the primeval forests of India and its islands, preferring the close covers of mountainous districts; they are commonly seen in parties of 8 or 10, which run rapidly among the brushwood when alarmed. Macartney's or the fire-backed pheasant (*G. ignitus*, Shaw), a native of Sumatra, is about 2 feet long; the general color is deep black, with steel-blue reflections; on the middle of the back is a fiery orange patch, with brilliant gloss; rump and tail coverts broad and truncated, bluish green with orange edges, and central feathers white, legs and feet vermilion; head with a crest of slender barbed feathers; the female is of a cinnamon brown color. The silver pheasant (*G. nycthemerus*, Hodgs.) has the throat, under parts, and ample crest glossy purplish black, the feathers being generally lanceolate; the rest of the plumage pure white, the webs of the feathers of the back diagonally streaked with black; legs and feet purple lake, and large, naked, velvety space about the eyes bright vermilion. It is a powerful bird, and a match for a game cock; it is a native of northern China, where it is often kept in a tame state; being very hardy, it is frequently carried to Europe, and, with the golden pheasant, forms a pleasing addition to aviaries. About a dozen other species of the genus are described.—The genus *ceriornis* (Swains.) includes the brilliant tragopans; these have a short, thick bill, arched and obtuse; wings ample and very concave; tail large and rounded, and tarsi robust; the head has a large horn over each eye, and under the throat two short naked wattles. They are peculiar to the dense pine forests of the mountains of India; they are solitary and hard to approach, and discoverable only by their shrill whistle; their food consists of grains, roots, larvæ, and insects. The Nepaul tragopan or horned pheasant (*C. Lathami*, Gray) is a very beautiful bird, about as large as the domestic fowl; the prevailing color is purplish cinnamon red, the wings and upper parts umber brown, the tip of each feather with a white eye spot, largest on the sides; tail almost concealed by the ample coverts, which have a conspicuous white spot; bare skin of head bluish purple; long feathers of crown purplish black, deep crimson red at the occiput. The golden-breasted pheasant (*C. melanocephala*, Gray) is a still more beautiful species; the wings and upper parts are deep wood-brown, each feather with a white eye spot surrounded with black; back of neck, upper back, and shoulders purplish red; black *crest* of disunited feathers; horns and long wattles bluish purple, and beneath a patch of brilliant golden orange of hard horny feathers; rest of under parts deep black. These tragopans belong to the genus *satyra* of Lesson.—In the sub-family *lophophorinæ* belong some very remarkable pheasants. The genus *lophophorus* (Temm.) has the upper mandible very much curved over the lower, the 4th and 5th quills longest, tail ample and rounded, and tarsi armed with a short spur. The Impeyan pheasant (*L. Impeyanus*, Vieill.) is about 2 feet long; the colors of the plumage defy description or representation, being resplendent with ever-changing hues of green, steel-blue, violet, golden, and bronze, dense and metallic in appearance, but soft and velvety to the touch; the middle of the back pure white, and the tail bright chestnut with transverse bars of a duller tint; on the head is a crest of feathers with naked shafts and oval tip of metallic hue; the female is smaller, of a general reddish brown color, mottled with spots and bars, with throat and fore neck white. This species, named in honor of Lady Impey, inhabits the mountain ranges of the Himalaya and Nepaul, and, with many other beautifully plumaged birds, enlivens these dreary solitudes. In the genus *pucrasia* (Gray) the bill is short, broad at the base, and much arched; the 4th quill the longest, and the 3d and 5th equal; tail long and wedge-shaped, and tarsi rather slender. The Pucras pheasant (*P. macrolopha*, Less.) is rich brown above, the feathers lanceolate, and the under parts rich chestnut bordered with long lanceolate white plumes; head, throat, and neck beautiful green, with blue and violet reflections; patch of white on the sides of neck; crest of long broad feathers, of the color of the head and neck, the shortest ones reddish yellow. It inhabits the alpine regions of India, where its flesh is highly esteemed. In the genus *tetraogallus* (Gray) belongs the Caucasian pheasant (*T. Caucasicus*, Pall.), cinereous above with minute undulations and edges of cream color; breast cinereous, with brown arrow heads on the sides, abdomen creamy white, vent and thighs black. This species, found in the inaccessible mountain ranges of N. and W. Asia, is very difficult to procure; it is said to warn the wild goats of the proximity of man by a curious whistling note; the food consists principally of grass.

PHELPS, Almira Hart Lincoln, an American teacher and writer, born in Berlin, Conn., in 1793. At the age of 19 she taught school at her father's house, and not long afterward took charge of the Sandy Hill (N. Y.) female academy. In 1817 she was married to Simeon Lincoln of Hartford, then editor of the "Connecticut Mirror." He died in 1823, and soon afterward she became associated with her sister Mrs. Emma Willard in the direction of the female seminary at Troy, N. Y., where she continued until 1831, when she was married to the Hon. John Phelps of Vermont. During her residence at Troy she published a text book on botany, which has undergone several revisions, and still continues in use for schools and colleges. In 1838 she took charge of a seminary at West Chester, Penn., and afterward taught in Rahway, N. J. In 1841, on the invitation of the bishop of Maryland, Mr. and Mrs. Phelps took charge of the Patapsco institute, a diocesan female school, which soon attained a high reputation; and after the death of Mr. Phelps in 1848 Mrs. Phelps conducted it alone until 1856, when she resigned. She now (1861) resides in Baltimore, Md. She has published "Familiar Lectures on Botany" (Hartford, 1829; revised and enlarged with a supplement, New York, 1861); "Dictionary of Chemistry" (New York, 1830); "Botany for Beginners" (Hartford, 1831); "Geology for Beginners" (Brattleborough, 1832); "Female Student, or Fireside Friend" (Boston, 1833); "Caroline Westerly" (New York, 1833); "Chemistry for Beginners" (New York, 1834); "Progressive Education," translated from the French (Boston, 1834); "Lectures on Natural Philosophy" (New York, 1835; revised and enlarged, 1854); "Lectures on Chemistry" (New York, 1837; revised ed., 1857); "Natural Philosophy for Beginners" (New York, 1837); "Ida Norman" (New York, 1854); "Hours with my Pupils" (New York, 1859); and "Christian Households" (1860).

PHELPS, Anson Greene, an American merchant, born in Simsbury, Conn., in March, 1781, died in New York, Nov. 30, 1853. He lost both his parents while young, and learned the trade of a saddler. At the age of 18 he removed to Hartford, and established himself there in his trade, and founded also a branch business in Charleston, S. C. In 1815 he engaged in New York city as a dealer in tin plate and heavy metals. Having accumulated a large fortune partly by investments in real estate, he devoted himself with great zeal to benevolent enterprises, and was president of the New York blind asylum, the American board of commissioners for foreign missions, and the New York branch of the colonization society. At his death he bequeathed to various charitable institutions sums amounting in the whole to $371,000, and placed in the hands of his only son a fund of $100,000, the interest of which was to be distributed in charity at his son's discretion. In addition to large legacies to 24 grandchildren, he intrusted to each a fund of $5,000 for charitable purposes.

PHELPS, Elizabeth Stuart, an American writer, born in Andover, Mass., Aug. 13, 1815, died there, Nov. 30, 1852. She was a daughter of Professor Moses Stuart. In 1842 she was married to the Rev. Austin Phelps, now professor in the Andover theological seminary. "The Sunny Side," one of the most popular of her works, after several rejections by different publishers, was at last published by her friends, and almost immediately attained an unprecedented sale, reaching its 40th thousand in less than two years, and continuing to sell largely to the present time. It was followed, in rapid succession, by the "Kitty Brown Series" (4 vols., Philadelphia, 1849), "Peep at Number Five," "Tell-Tale," "Angel over the Right Shoulder," and soon after her death by "The Last Leaf from Sunny Side," all published at Boston. These, as well as some compilations of her magazine and newspaper articles, have met with a very extensive sale.

PHENE, a name sometimes given to benzole, a compound of 12 atoms of carbon and 6 of hydrogen, probably united according to the formula $(C_{12}H_5)H$. A series of compounds are recognized founded on the hypothetical base, $C_{12}H_5$, which is known as phenyle, and the series as the phenic series. Phenole, or phenic acid, known as carbolic acid, is a principal member of this series, and its compounds are phenates. (See Benzole, and Carbolic Acid.)

PHERECYDES. I. A Greek philosopher of Syros, one of the Cyclades, who flourished about 544 B. C., and is said to have been the teacher of Pythagoras. He studied under Pittacus of Mitylene, was a rival of Thales, travelled in Egypt, and was instructed by the Egyptians and Chaldeans. He wrote a philosophical work, which was extant in the Alexandrian period, in which he maintained that there were 3 principia, Zeus or Æther, Chthon or Earth, and Cronos or Time, and 4 elements, fire, air, earth, and water; and that from these all things sprang. His distinguishing doctrine was that of metempsychosis, or according to others that of the immortality of the soul. He was the first to write a philosophical treatise in prose, and according to some the first to write in prose at all. The usual account of his death is that he was eaten up by worms and insects. The fragments of Pherecydes are printed by August Wolf in the first part of his *Literarische Analecten* (Berlin, 1817). II. A Greek logographer, surnamed of Athens, because he passed most of his life in that city, or of Leros, because he was born in that island. He flourished probably about 480 B. C. He wrote a work on mythology, which is mentioned under various titles, and consisted of 10 books, beginning with the genealogy of the gods, and coming down to the families of the heroic age. The fragments of it have been collected by

Sturz, *Pherecydis Fragmenta* (Leipsic, 1824), and by the Müllers in *Fragmenta Historicorum Græcorum.*

PHIDIAS, the son of Charmides, the most illustrious sculptor of antiquity, born in Athens probably in 490 B. C., died there about 432. The details of his personal history are to be gleaned only from detached passages in the writings of classic authors and scholiasts; and so conflicting are these statements, that the dates of the most important events in his career can only be approximately ascertained. His biography is consequently in a large degree the result of a balancing of authorities. He is supposed to have belonged to a family of artists, and is said to have originally occupied himself with painting, an art practised with great repute by his nephew Panænus. He was instructed in sculpture by two native artists, Hegias and Ageladas, and probably between the ages of 25 and 30 began to exercise his calling in Athens. His subjects were for the most part sacred, and among the works attributed to him are no fewer than 9 statues of Athena (Minerva), the tutelary goddess of his native city. One of these, at Pellene in Achaia, was perhaps his earliest public work. About the same time he executed the group of 13 bronze statues dedicated by the Athenians at Delphi out of the tithe of their share of the spoils taken from the Persians at Marathon, and the colossal bronze statue of Athena Promachus in the Athenian acropolis, 50 or 60 feet in height, and visible from a considerable distance by ships approaching Athens, which is also said to have been made from the spoils of Marathon. Pericles seems to have been so impressed with the genius of Phidias, that he not only intrusted him with the execution of the principal statues intended to adorn the public buildings of Athens, but made him general director of all the great works of art in progress in that city, including the Propylæa of the acropolis and the Parthenon. For the latter he executed the colossal chryselephantine or ivory and gold statue of Athena, which stood in the *prodomus* or front chamber of the temple, and which, with the statue of the Olympian Jupiter at Olympia, constituted the grandest productions of antique plastic art. It embodied the idea of the virgin goddess, as that of Athena Promachus did of the warrior goddess, and was formed of plates of ivory laid upon a core of wood or stone for the flesh parts, while the drapery, the ægis, the shield, the helmet, and other accessories were of solid gold, adorned with devices and elaborately engraved with subjects taken from Athenian legends. No expense was spared by the Athenians to make this statue worthy of the shrine in which it was enclosed; and it is said that when the sculptor intimated his desire to execute it in marble, they directed him to employ those materials which were the most costly. The weight of the gold has been estimated at between 40 and 50 talents, or somewhat more than $500,000. It was removed from the statue by Lachares in the time of Demetrius Poliorcetes, about 296 B. C. Previous to the time of Phidias, colossal statues when not of bronze were acrolithic, the head, hands, and feet being of marble, while the body was of wood, concealed by real drapery; and the substitution of ivory and gold for these materials is believed to have been his invention. Supposed copies of the statue are in existence, and restorations have been attempted by Quatremère de Quincy and others. The architectural sculptures of the Parthenon, which were in all probability designed by Phidias, and perhaps in some instances executed by him, are described under the head of ELGIN MARBLES. The Athena was finished in 438, and, with the Parthenon, was dedicated in the same year. Shortly afterward, at the invitation of the Eleans, Phidias commenced at Olympia the colossal chryselephantine statue of Jupiter, which, in the opinion of all the authors of antiquity who have written upon the subject, was the sculptor's masterpiece. The god was represented as seated upon a throne of cedar wood, holding in one hand an ivory and gold statue of Victory and in the other a sceptre, with his feet supported by a footstool, which, as well as every part of the throne, and its base, was elaborately adorned with gold, ivory, ebony, and gems, with enchased work and paintings, with sculptures of precious metals, and with numerous accessory groups and bass-reliefs representing allegories or legends. "The idea which Phidias essayed to embody in this, his greatest work, was that of the supreme deity of the Hellenic nation, no longer engaged in conflicts with the Titans and the giants, but having laid aside his thunderbolt, and enthroned as a conqueror, in perfect majesty and repose, ruling with a nod the subject world, and more especially presiding, at the centre of the Hellenic union, over those games which were the expression of that religious and political union, and giving his blessing to those victories which were the highest honor that a Greek could gain. . . . . Expression was given to this idea not only by the whole proportions and configuration of the statue, but more especially by the shape and position of the head. The height and expansive arch of the forehead, the masses of hair gently falling forward, the largeness of the facial angle, which exceeded 90 degrees, the shape of the eyebrows, the perfect calmness and commanding majesty of the large and full-opened eyes, the expressive repose of all the features, and the slight forward inclination of the head, are the chief elements that go to make up that representation which, from the time of Phidias downward, has been regarded as the perfect ideal of supreme majesty and entire complacency of the 'father of gods and men' impersonated in a human form." (P. Smith.) Pausanias, who has given the fullest description of the statue, relates that the god testified his approval of the sculptor's work by striking the pavement in front of it with lightning; and according to Arrian it was considered a calamity to die without having seen the Jupiter of Phidias. The statue was nearly 60 feet in height, and occupied Phidias and his assistants, among whom were Colotes and Alcamenes, sculptors, and Panænus the painter, between 4 and 5 years, from 437 probably to 433 B. C. The Eleans granted him the honor of inscribing upon the footstool the following inscription:

Φειδιας Χαρμιδου υιος Αθηναιος μ' εποησεν;

and his descendants were intrusted with the office of cleaning and preserving the statue. It was removed by the emperor Theodosius I. to Constantinople, where it perished by fire in A. D. 475. Restorations of it have been attempted by Quatremère de Quincy and Flaxman. Upon the completion of the statue Phidias returned to Athens, where a formidable party was aiming at the overthrow of Pericles. Fearing to attack the great Athenian statesman directly, his enemies sought to undermine his influence by persecuting his friends; and Phidias, who for many years had been on terms of intimacy with Pericles, was accused by one Menon, a workman employed upon the Parthenon, of having stolen a portion of the gold appropriated to the chryselephantine statue of Athena. As the gold however had been affixed to the statue in such a manner that it could be removed, the accusers were challenged to substantiate their charge by weighing it, which they shrank from doing. Another charge was then made against the sculptor of having introduced portraits of himself and Pericles in the bass-reliefs of the shield representing the battle of the Amazons. As this act was supposed to imply a dishonor to the national religion, he was thrown into prison, where, according to Plutarch, he died either by poison or by a natural death. In addition to the works mentioned, Phidias executed a number of statues of deities for Athens and other cities of Greece, including an acrolithic Athena at Platæa, and a famous chryselephantine Æsculapius at Epidaurus.—Phidias was the first to break away from the stiff, archaic style of the earlier school of Greek sculptors, and to aim at pure and severe ideal beauty. He is said never to have imitated exactly any human model, however beautiful, nor do his works exhibit any of that sensuous grace which in the productions of succeeding sculpsors tended to deprave taste and to corrupt the art. Dignity, majesty, and repose were his distinguishing characteristics, and in no other artist have they probably ever been united in so high a degree. He has been called the "sculptor of the gods," and his age the golden age of sculpture.

PHIGALIA, or Phialia, an ancient town of Arcadia, near the borders of Messenia and Elis, on the right bank of the river Neda, of which ruins still exist near the modern village of Paulitza. Nothing is known of its origin. It preserved its freedom against the encroachments of the Spartans, and although in 559 B. C. the inhabitants were compelled to abandon it, they soon returned. Its celebrity is chiefly due to the temple, which was situated on Mt. Cotylion, about 6 m. N. E. from the city, and was described by Pausanias to be, after that at Tegea, the most beautiful of all the temples of the Peloponnesus. It was built of yellowish brown limestone by Ictinus, who in conjunction with others had erected various public works at Athens during the age of Pericles, and was dedicated to Apollo Epicurius, because the god had cured the citizens of the plague during the Peloponnesian war. Its ruins were explored in 1812, and the entire sculptured frieze of the cella was brought from it for the British museum in 1814. It represents the contests between the centaurs and lapithæ and between the Amazons and the Greeks, and is known as the Phigalian marbles.

PHILADELPHIA, the metropolis of Pennsylvania, and the second city of the United States in population, situated on the Delaware river, 96 m. by the course of the stream and bay from the sea, 136 m. N. E. from Washington, and 87 m. S. W. from New York. The old state house, now independence hall, which is near the centre of the city, is in lat. 39° 56′ 59″ N. and long. 75° 9′ 54″ W. The tide ascends the Delaware river far above the city on the E. side, and the Schuylkill on the W. side to its upper or N. limit, thus surrounding it with tidal waters. Its site is mostly a plain from 2 to 4 m. in width between these rivers, elevated 30 to 80 feet above tide. This spacious plain extends beyond both rivers E. and W., and on it are built the suburban city of Camden E. of the Delaware, and West Philadelphia W. of the Schuylkill. Northward the surface rises in low hills, upon which, and along the borders of the rivers, several populous manufacturing and residential suburbs are built within the municipal limits. The densely built part of the city is about 5 m. in extent along the Delaware, and from 3 to 3½ m. in width E. and W., covering an area of nearly 12 sq. m. Previous to 1854 the municipality of Philadelphia proper was confined to the belt between the two rivers originally assigned as the city limits by Penn, an area nearly a mile in width by two miles in length. Adjoining this several districts possessed distinct municipal organizations, those of Southwark and Moyamensing on the S., Northern Liberties, Kensington, Spring Garden, and Penn Township on the N., and West Philadelphia beyond the Schuylkill. Most of this area being then compactly built upon, and the less populous suburbs rapidly becoming connected with the central city, the municipalities were consolidated in 1854, and extended to embrace the entire county, an area of 120 sq. m. Most of this added surface lies N. of the old city; it is thickly studded with villages, and has also the large towns of Frankford, Germantown, and

Manayunk, each containing from 8,000 to 10,000 inhabitants. The immediate front on the Delaware was originally a bluff bank of gravel 20 to 30 feet high, on the slope and river edge of which Penn forbade the settlers to build, intending it to afford an open prospect and free public levee. A few wharf buildings only were permitted until after Penn's death; it is now closely built up with lofty warehouses on narrow streets, and many efforts have been made to restore some degree of the original plan, Stephen Girard having left a large sum of money to the city for that purpose. The water on this front is 25 to 60 feet deep at the pier heads at low tide for more than a mile and a half, and the strong current setting on the W. shore at both flood and ebb tide prevents encroachments on the harbor by deposit. The rise of tide is but 6 feet, and floods or overflows are unknown. The foundation of the city is mainly a dry, well drained gravel, making the sewerage easy and perfect. Ledges of gneiss and imperfect granite underlie the upper part of the city; Fairmount reservoir rests on a large and peculiar ledge of this sort, 80 feet high, near the Schuylkill in the N. W. part.—The decennial progress of population since 1790 is as follows:

1790	42,520	1830	167,325
1800	70,287	1840	258,037
1810	96,287	1850	408,762
1820	119,325	1860	565,529

The whole number of persons of foreign birth in 1860 was 121,699, nearly 20 per cent. The deaths in 1860 numbered 11,565, and the births for the last 6 months 8,484, no trustworthy record having been previously kept.—The original regularity of plan on which the streets were laid out has been preserved in all additions to the city. High street, now Market, the great central street E. and W., is 100 feet wide, and built up for more than 3 m. Broad street is the central street N. and S., 113 feet wide, and built upon for over 3 m. The other great streets are from 50 to 66 feet wide, forming squares with sides of from 400 to 450 feet, and regularly succeeding each other each way from the central streets named. In most cases the squares are subdivided by small streets laid out at a later period. Chestnut street, the first E. and W. street S. of Market, is the fashionable thoroughfare. Walnut, Locust, Spruce, and Pine streets succeed each other on the S., and are occupied mainly by wealthy residents; further southward are Lombard, South, Shippen, Fitzwater, Christian, and Washington. N. of Market there are, first, Arch, Race, and Vine, leading and wealthy streets; next Callowhill, Spring Garden, Green, &c. The banking and financial centre is in Third and Walnut streets; the dry goods and other jobbing trade in Third and Market streets; the commission houses in Front and Chestnut; the shipping and provision trade on Water street and Delaware avenue; the newspaper offices on Third and Chestnut. Broad street has a large business in produce, brought to it by western railroads. The streets running N. and S. are numbered from the Delaware, Front, Second, &c., to Twenty-fifth street. Houses on all the streets are now numbered in hundreds corresponding to each square, from Front street westward, and from Market street N. and S.; thus at Tenth street W. the numbers are 1,000, 1,002, &c.; and at 10 squares N. or S. of Market street the same numbers occur on streets running N. and S. The pavements of the streets generally are of cobblestone, with brick gutters, granite curb, and brick sidewalks. Cubical blocks are laid in Chestnut, Third, Walnut, and Second streets, in the business centre. The city is lighted mainly by gas lamps, of which there were 5,844 in 1860, and 401 lamps burning fluid; total number, 6,245. Of gas supplied to these in 1860 the total was 119,994,816 feet; and the total cost of the lighting department for that year was $225,000.—There are 7 squares planted as parks within the densely occupied portion of the city: Independence square, surrounding the state house; Washington square near it on the S. W., celebrated as the potter's field of the revolution, and as the spot on which the corner stone of a national monument to Washington has been laid; Franklin square, with a fountain; Logan square, with a deer park; Penn square in the centre of the city, &c. Hunting park in the northern suburbs, and Fairmount park along the Schuylkill on the N. W., are in rapid progress of improvement on an extensive scale. Many highly improved cemeteries exist near the city, the chief of which is Laurel Hill, 5 miles N. W. Others are Woodlands, Cathedral, Odd Fellows', Mount Moriah, Glenwood, Monument, and Mount Vernon. The churchyard cemeteries within the city were originally large, and Franklin, with many other historical names, may be found in Christ church and other burial grounds. Laurel Hill is justly celebrated and much visited; it has an area of but 25 acres. Adjacent to it is South Laurel Hill, occupying 30 acres in a similarly attractive position.—The style of building has always been principally of brick, the vicinity producing very superior pressed brick at a low cost. Numbers of brick buildings remain standing and in good preservation which were erected before 1760; those built since 1800 have marble facings and marble steps, and are remarkably uniform in height and general character. All are conspicuous for neatness and durability; even the cheaply built blocks and suburban streets intended for laborers' residences are distinguished for neatness, and differ externally from those of the wealthier class more in size than in any thing else. Tenement houses are unknown. For the best residences marble and brown stone have been much used, and in the business streets iron fronts are common. Of public buildings, the principal in marble are the old United States bank (now the Girard bank), the second United States bank (now the custom house, costing $500,000), the old Pennsylvania bank, and the United States mint, all fine marble buildings of Grecian architecture. Girard college is the chief building of this class, and the finest in the United States; it is built in the Corinthian style, 218 feet long, 160 feet wide, and 97 feet high, at a cost exceeding $1,000,000. The merchants' exchange is a fine structure of marble, with an ornamented front on Dock street, a semicircular colonnade of 8 pillars, and a spacious rotunda within, on that side. The farmers' and mechanics' bank in Chestnut street, recently erected, is a very superior structure of marble in the modern style; and adjoining it is the Philadelphia bank, a fire-proof granite building of great cost, built in 1856 and 1857. The old Christ church (Episcopal), celebrated in early colonial times, is still a fine building, and in perfect preservation. St. Peter's, in Third and Pine streets, a church of note in historical times, is also still preserved. The church of the Holy Trinity, recently erected in Twentieth and Walnut streets, is a fine specimen of Norman architecture, as are also St. Mark's, in the later or English Gothic style, in Sixteenth and Locust streets; St. Luke's, in the Grecian style, &c. The West Arch street Presbyterian church is a very handsome and spacious structure in the Roman Corinthian style; the West Spruce street, the Calvary, the Logan square, and other churches are fine buildings in various styles. The new Catholic cathedral on Logan square is an imposing structure of brown stone, in the classic or Roman style, not yet fully finished. The academy of music, recently erected, is without a superior for space and internal beauty. Arch street theatre is perhaps the most noted of theatres proper; next are the Walnut and the Continental, both in Walnut street between Eighth and Ninth; the Olympic in Race street; Sanford's opera house; a German theatre in Callowhill street, &c. Concert hall in Chestnut street, national hall in Market, musical fund hall in Locust, the assembly building, Jayne's hall, metropolitan hall, national guards' hall, and many others, are occupied for public meetings and entertainments. Carpenters' hall, the first place of meeting of the continental congress, is still maintained by the carpenters' society. Independence hall generally signifies the whole of the old state house, but more specifically the large eastern room of the lower floor. In this hall Lafayette had a great public reception in 1824, and in 1830 a public movement was made to restore it to its original condition, and to set it apart "for dignified purposes only." The portraits of the great men of the revolution were procured, and historical relics were placed there for permanent preservation. In 1854 the consolidated city took a renewed interest in it, the old independence bell was taken from the tower and placed in the hall, a large number of portraits from the Peale gallery were hung on the walls, and a keeper was appointed.—The hotels of Philadelphia are not behind those of other metropolitan American cities. The Girard house in Chestnut street, and the La Pierre in Broad street, have been celebrated for years; both are fine architectural structures, built in part of brown stone. The continental hotel, recently erected, is equal if not superior to any other in the United States in size and beauty; it covers 41,536 square feet, and is 235 feet in depth by 194 feet front. The main hall is 185 feet in depth, and the central open area 38 by 78 feet. It has over 100 complete suites of family rooms, and employs 280 persons in its regular care. The building is of brown stone, divided into 6 stories in the front and 9 in the rear. Very many hotels exist in various parts of the city with the signs, arms, and insignia of revolutionary times. The chief business streets are now occupied with a large number of costly and superior buildings of marble, granite, iron, and sandstone. The number of buildings erected in the city in 1860 was 2,876, and the census of that year gives 89,978 as the total number of dwellings. There are 350 places of worship, viz.: 32 Baptist, 63 Episcopal, 14 Friends', 7 Jewish, 14 Lutheran, 59 Methodist Episcopal, 4 Methodist Protestant, 20 Presbyterian New School, 34 Presbyterian Old School, 20 other Presbyterian, 30 Roman Catholic, 2 Unitarian, 3 Universalist, 28 of other denominations, and 20 of various denominations for colored people. There are 6 Bible societies, 18 missionary societies, and 12 tract and religious publication societies. The operations of many of these are very extensive, particularly the Pennsylvania Bible society, the American Sunday school union, the Presbyterian board of publication, &c.—The principal libraries of Philadelphia are the Philadelphia library, founded by Franklin, and combined with the Union and Loganian libraries. It had 70,000 volumes on Jan. 1, 1861. It is free to strangers, and open from sunrise to sunset daily. Stock and shareholders can use it as a circulating library. The philosophical society has a library of 21,000 volumes, and a very valuable collection of coins, medals, maps, charts, &c., of scientific and historical value. The mercantile library has 21,500 volumes, with a large membership. Its income in 1860 was $11,351, and the number of volumes lent to subscribers and members was 87,500. It is open from 9 A. M. to 10 P. M., and has a news reading room with 150 newspapers and 65 periodicals. The Athenæum has a library of 13,500 volumes. The academy of natural sciences, on Broad street, has a very valuable scientific library of 23,000 volumes, and the largest museum of natural history in the country, containing over 25,000 mounted specimens in ornithology alone. The apprentices' library has 15,000 volumes. The Franklin institute has about 7,000 volumes, a news room, and a course of scientific lectures; the mechanic and inventive arts are especially favored in the plan of its operations. The university of Pennsylvania has a library of 5,000 volumes, and a fine anatomical museum. The Pennsylvania hospiial has a library of 10,000 volumes, and various other institutions possess considerable libraries. There are also a number of large private libraries.—The academy of fine arts was established in 1807; it holds annual exhibitions, and owns about 1,000 valuable paintings. The medical colleges of the city are celebrated. The oldest is the medical school of the university, which was established in 1765; it has 7 professors, and on its catalogue for 1860–'61 there are 466 students; the number of alumni is now about 8,500. The Jefferson medical college was established in 1825, and it has had extraordinary celebrity and success, the classes often numbering more than 600. The Pennsylvania medical college is a successful institution, with an annual class of about 200. There are several others, of more or less celebrity, including two female medical colleges. There is also a college of pharmacy, with 3 professors, for the instruction of druggists. The total number of students in the annual courses of these colleges is about 1,500. The literary colleges of Philadelphia, though generally successful, are not conspicuous. There are four whose organization and course of instruction entitle them to be so called: the university of Pennsylvania, the polytechnic college, the high school, and Girard college; though the last two are chiefly characterized by other features. The university has a law school, a regular collegiate department, and a scientific course. The Franklin institute has a scientific course, but does not confer degrees. The polytechnic college has a course described by its title. The high school, sustained by the city as the crowning feature of its free school system, has a thorough course of collegiate training, and confers the honor of degrees. The system of public schools of Philadelphia was established on a free basis in 1818. It is supported by city tax, and for the year ending Jan. 1, 1861, its total cost was $512,014. The whole number of schools at that date was 335, of which 2 were high schools, 54 grammar schools, 50 secondary, 170 primary, and 59 unclassified. The whole number of scholars was 63,522, and of teachers 1,197. The high school for boys had, at the beginning of 1861, 542 students; 11 were graduated from a 5 years' course, and 23 from a 4 years' course, in 1860. The girls' high school was organized in 1848, and during 1860 had 340 pupils. Its objects are mainly those of a normal or teachers' school. The public schools are in large, well built edifices, all owned by the city, and distributed so as to give access to them by the entire population. Text books are furnished by the city. Candidates for the higher grades undergo a rigid examination, but are subjected to no test even for graduation at the high school. The number of private schools of all grades is about 200, with an attendance of about 8,000. Girard college is a free school for orphans founded by Stephen Girard, and wholly a private charity, though placed under the guardianship of the city. In 1860 it had 340 students or beneficiaries, all of whom are domiciled and wholly supported at the college during their scholarship; but the period may be longer or shorter according to the capacity developed, and the judgment of the directors. On leaving, every student must be apprenticed to a trade or profession. The cost of the buildings alone was $2,000,000, including the principal one before spoken of. The cost of maintenance of the college in 1860 was $81,034. The estate, called the Girard trust, confided to the care of the city, is valued at over $2,000,000, but a large share of it is at present unproductive. The revenues beyond the wants of the college go to the improvement of the city, and to some minor charities; their total amount in 1860 was $193,749.—There are 18 daily, 4 tri-weekly, and 46 weekly newspapers in Philadelphia. Of magazines and periodicals the number is 44, about 30 of which are issued monthly. Two daily and 2 weekly journals are in the German language.—The benevolent institutions of Philadelphia are numerous. The Pennsylvania hospital was founded in 1752, wholly by private endowment. It has spacious buildings occupying a square near the centre of the city, and an insane department erected and maintained on a most liberal scale in the western suburbs. The hospital department treated 1,956 cases in the year ending with May, 1860, and the insane asylum had 274 patients under care; both have a class of patients who pay, though two thirds are treated without cost. There are, in all, 15 hospitals and dispensaries; 14 asylums, including 3 widows', 3 Magdalen, 4 orphan, and 2 insane asylums, and the U. S. naval asylum; 14 homes for the indigent, 7 of which are for friendless and destitute children, and one news boys' home; 4 lying-in charities; 7 societies for the relief and employment of the poor; 7 soup societies; 7 charity education societies, which include a school for feeble-minded children which is very successful; the house of refuge, which is in part penal; the institution for instruction of the blind; and the institution for the deaf and dumb. This last had 115 boys and 102 girls under its care at the close of 1860. The institution for the instruction of the blind is supported mainly by private endowment, but receives aid also from the state. It had 165 inmates on Jan. 1, 1861, of whom 8 were paying pupils. The indigent are employed as far as possible, goods to the value of $12,717 having been made in the year 1860. There are also a city pest hospital; a most important and useful prison society, which annually procures the relief of a large number of persons improperly committed; a society for the recovery of drowned persons; the union benevolent association, which expends $10,000 yearly in aid of the poor; a Friends' almshouse, and many other charity and benevolent trusts and societies. The secret beneficial societies number about 850, odd fellows, temperance societies, &c. The city almshouse occupies very extensive buildings west of the

Schuylkill; it had 3,091 inmates on Jan. 1, 1861. It is under the control of the board of guardians of the poor, who expended $224,935 for the almshouse and outside poor in 1860. The house of refuge for juvenile delinquents, maintained in part by the state, is a penal institution; it had 459 inmates at the close of 1860. It has extensive buildings erected at a cost of $350,000, work rooms, &c., and in 1860 cost for maintenance $46,383, one half of which was paid by the state; the eastern state penitentiary is in Philadelphia; its penal discipline is on the plan of solitary confinement, and it was here that this system originated; it had 464 convicts on Jan. 1, 1861. There is one large city prison only, which has departments representing the penitentiary, county gaol, and workhouse purposes. The total number of commitments in 1860 was 20,789, and the expenditure for its maintenance was $62,133. The police force numbers 733 men, all of whom are uniformed; they made 32,051 arrests in 1860. A police and fire alarm telegraph communicates with all parts of the city. The number of fires in 1860 was 398, and the loss of property by fire $363,232. There are 90 fire companies whose organization is recognized, and whose expenses are in part paid by the city, liberal appropriations being made for the companies, particularly those maintaining steam fire engines; but the system is voluntary. These companies have 26 steam fire engines, 46 hand engines, and 104 hose carriages. The active members number 8,000, and the total of active, honorary, and contributing members is 11,700. An association for the relief of disabled firemen numbers 500 members, and has a capital of $26,000.—The municipal government consists of a mayor, who is elected for 2 years; a select council, composed of one member for each ward, elected for 2 years; a common council, composed of one member for every 1,200 taxable inhabitants, for one year. The election is held on the first Tuesday in May. There are 24 wards, 24 members of the select council, and 95 members of the common council. In each ward aldermen are elected for 5 years, in number according to population, the whole number being 78 in 1860, who are also justices and committing magistrates. The revenue raised for support of the city government in 1860 was $2,724,709, produced by a tax of $1.75 per $100 on $155,697,669 of assessed valuation of real and personal property. The chief items of expenditure were: for highways, $404,536; police, $420,400; and fire department, $65,985. The funded debt of the city is $20,962,409. The total receipts of the city treasury for 1860 from all sources were $5,127,496, and the expenditures $5,508,704. The valuation of real and personal property in Philadelphia for 1861 was $154,038,707, of which only $2,712,702 was personal. The number of tax payers was 114,836.—Water works were first erected in 1799, the reservoir being in the present centre of the city at Penn square. In 1812 the Fairmount works were begun, and in 1827 the present admirable system of supply from them was completed. These works are remarkably beautiful, and have long constituted one of the principal attractions of the city. The water is elevated 92 feet to 4 reservoirs, which cover an area of about 4 acres, with 12¼ feet depth of water when full, and a capacity of 22,131,976 gallons. These reservoirs stand on a single block of rock, with no other elevations near it, the walks overlooking the city at a height of 100 feet. The entire present system of water supply is by 4 distinct works; that at Fairmount operates by water power; the Schuylkill works employ 4 steam engines; the Delaware works have 2 powerful engines, and the 24th ward works 2 engines. All the works in 1860 raised 7,465,740,277 gallons of water, or 75,886 tons daily, of which the Fairmount works supplied one half. The direct cost of raising the water was $1.74 per million gallons; the receipts for the year from water rents were $558,531, and the expenses of the works $198,269, leaving a profit of $360,262. The total length of water pipe in use in 1860 was 325⅓ miles.—Gas works were first constructed on a general scale in 1835; they were principally conducted by the authorities of the original city limits, and were very successful. In 1855 and 1856 the works owned by the municipalities were consolidated with those of the city proper; and in 1859 the works of two companies, previously independent, were purchased, bringing the whole service under the control of the city as its property. In 1860 the several works made 639,578,000 feet of gas, which was supplied to consumers at $2.25 per thousand feet. The total length of street mains is 383 miles; the total cost of the works $3,763,904; the profits of the business of 1860 were $408,435, exclusive of interest on the cost of the works. Great care was taken in the original establishment of the city gas works to secure the best improvements then effected in the manufacture of coal gas in European cities, and they have from the outset furnished gas cheaper than in any other American city.—The mint of the United States was founded at Philadelphia in 1792. It occupies a marble building in Chestnut street, erected at a cost of $200,000. It has coined up to June 30, 1860, of gold, $326,928,934; of silver, $93,951,766; of copper, $2,545,813; total coinage since 1793, $423,426,504. This is exclusive of coinage at the branches of the mint. The highest coinage of any year was $60,111,249 in 1853; the coinage of the year ending June 30, 1860, was $5,553,653. The amount coined varies very greatly, according to the course of exchanges, rather than the production of gold. In the early part of 1858 coinage was brisk for a few weeks, but generally the last 6 years have exhibited a coinage of less than $10,000,000 yearly, while from 1851 to 1854 inclusive the average was $50,000,000 yearly. Coinage is again rapid in the beginning of 1861, over $4,000,000 being coined per week at the first of February.—The system of street railroads for passengers only was introduced in its best form in Philadelphia in 1858, since which time 18 distinct roads have been laid within the city, having a total length of track of 155 miles. The plan of the streets particularly favors these roads in Philadelphia, and the fact that all are successful attests the immense use of them by the population of the city. They are laid with a broad rail as nearly as possible level with the pavement, and aid rather than hinder the use of the streets by carriages. The fare is uniformly 5 cents for any distance by one road, and 7 cents for an exchange ticket over two roads. The authorized capital of these roads is $8,500,000, but they were built at a cost of about $6,500,000. In 1860 they employed 500 cars, 3,000 horses, and 2,000 men. Cars for city railroads were built and sent to various parts of the United States, and even to England, during that year.—Several large market buildings, of a very superior character, have been erected in the city within 2 or 3 years past, generally by incorporated companies. There are 6 that contain from 300 to 500 stalls each, viz.: the eastern, 5th street; the farmers', Market street near 11th; the Franklin, 10th and Market streets; the western, 16th and Market streets; the union, 2d and John streets; and the farmers' western, 21st and Market streets. In parts of the city markets in the centre of the street still exist, owned by the city. For rents of markets the city in 1860 received $46,946.—There are 12 banks, with an aggregate capital of $12,106,855; 11 of these had, on Jan. 1, 1861, loans $26,991,290, specie $4,020,266, circulation $2,689,812, and deposits $15,261,925. The week's clearings were $17,805,734, and the balances $2,514,526. There are 15 savings banks, and 145 building, savings, and loan institutions. There are 3 incorporated commercial institutions, the board of trade, corn exchange, and merchants' exchange, each with halls, reading rooms, &c.—The business interests of the city are nearly equally divided between foreign commerce, manufactures, and the interior distributing trade. The value of foreign goods entered at the port of Philadelphia in 1860 was $15,190,755, and the estimated importation of steamer and other goods entered at New York by and for Philadelphia merchants was $30,000,000, of which $22,000,000 was foreign dry goods. The export to foreign ports from Philadelphia for 1860 was $7,843,510, the leading items of which were breadstuffs, provisions, and manufactures, each to the value of about $2,000,000. The coastwise commerce of the city is very large, and its export to other states of the Union is about $25,000,000 annually, and its coastwise import about $20,000,000. There were 592 foreign and 27,964 coastwise arrivals in 1860. The tonnage of the port on June 30, 1859, was 220,050; in 1860, 147 vessels were built, of 19,760 tons, and 84 foreign vessels were first measured, having 21,760 tons. The bar in the river below the city has 19 feet at low water and 25 feet at high water. The wharf front of the city has extraordinary depth of water, there being 57 feet at low water at the pier heads for half a mile, and not less than 30 feet for 3 m. of the river front. The occupied commercial front is 5 m. on the Delaware, and 1½ m. on the Schuylkill. There are 6 steam ferries to Camden and other suburbs across the Delaware, 3 leaving South street wharf, two from Market street, and one from Vine street. The number of steamboats plying up and down the Delaware between Philadelphia and the various towns is about 20. There are 14 steam lines to more distant points, the chief of which are the Boston line, two lines to New York, a line to Richmond, Va., one to Charleston, one to Savannah, two to Baltimore, &c. No regular trans-Atlantic steamship line now exists. A regular packet ship line to Liverpool employs 4 ships steadily; this was the first packet line established from the United States to that port. A number of sailing lines connect with southern ports. The coal trade outward employs 6,000 vessels, and in 1860 it carried 702,492 tons of coal to New England, 334,914 to New York, New Jersey, and Pennsylvania, 129,906 tons to the southern states, and 17,000 tons to foreign countries and California; total, 1,184,312 tons, worth on shipboard $4,250,000. The internal receiving and distributing trade is conducted on the Delaware and Raritan and Chesapeake and Delaware canals, which use capacious steam barges; on 4 railroad lines which reach the city from the east and New Jersey (the New Jersey central, by way of Trenton and the W. bank of the Delaware; the Camden and Amboy, at Camden; the Camden and Atlantic City; and the Camden and Cape May; the last just now (1861) completed), 3 railroads leading N. and W. (the North Pennsylvania, the Germantown and Norristown, and the Reading), and 4 leading S. and W. (the Pennsylvania central, the Westchester, the lower Westchester and Baltimore road, and the Philadelphia, Wilmington, and Baltimore). The weight of merchandise, mostly light goods, carried inland by railroad and canal, was about 400,000 tons in 1860. The central railroad alone carried 100,000 tons of through freight, and 67,000 tons of local freight westward from Philadelphia. The total value of goods sold to the interior was about $140,000,000, of which $78,000,000 was by jobbers of light goods. The railroads and canals carried to Philadelphia in 1860 very nearly 4,000,000 tons of coal, of the value of $14,500,000, and a heavy tonnage of produce, provisions, iron, and manufactured goods from interior works. The quantity of goods by the central railroad alone, exclusive of coal, was 278,780 tons; of which there was in cotton 14,336 tons, flour 52,000 tons, and grain 31,890 tons. The facilities for transacting heavy freight business are about to be increased by the extension of the central railroad across the lower part of the city to the Delaware.

city has from its foundation been conspicuously healthy. The separate municipalities constituting the aggregate city proved unfavorable to the preservation of order for a period of years previous to the consolidation. Minor riots were frequent between fire companies of the rival districts, and more or less of disturbance from this cause continued down to the better organization of the fire department in 1857. In 1835 riots were incited against the colored population, and again in 1838, when Pennsylvania hall, belonging to the anti-slavery societies, and occupied by their meetings, was burned by a mob. Other minor disturbances occurred from the same cause. In 1844 the districts of Kensington and Southwark were the scene of riots arising from the hostility between the Roman Catholics and "Native Americans;" the disturbance was protracted over a considerable time, the military were called out to enforce order, and some lives were lost.

PHILÆ, an island of the Nile in Nubia, just beyond the confines of Egypt, 6 m. S. of Aswan, in lat. 24° 1′ 34″ N., long. 32° 54′ 16″ E. It lies between the S. extremity of the island of Biggeh and the E. bank of the river, is a quarter of a mile long and about 500 feet broad, and is covered with picturesque ruins of temples, mostly of the times of the Ptolemies, with additions by the Roman emperors. These are principally at the S. end of the island. The chief temple is that of Isis, the portal of which bears the name of Nectanabis I., who reigned from about 374 to 367 B. C., while the wings were added by the Ptolemies a century or two later. Philæ is celebrated for its beauty, not only from its ruins, but from its palm trees and the grandeur of the surrounding scenery.

PHILEMON, an Athenian comic poet, born probably at Soli in Cilicia about 360, died in 262 B. C. He was the first writer of the new comedy in order of time, and inferior in celebrity only to Menander, from whom indeed he bore away the palm of victory in several dramatic contests. He began to exhibit plays about 330 B. C., and during his lifetime produced 97, of which not even the titles of many remain. The fragments of his extant works are usually printed in the principal editions of Menander. Philemon's subjects are chiefly love intrigues, and his plays are remarkable for their wit and elegance. According to one account, he died from immoderate laughter at seeing an ass eat figs from a countryman's basket; according to another, from joy at obtaining the prize in a dramatic contest.

PHILEMON AND BAUCIS. See BAUCIS.

PHILEMON, EPISTLE TO, a canonical epistle of the New Testament, written, according to the constant tradition of the ancient church, by the apostle Paul. Eusebius and Jerome attest its universal reception as a Pauline epistle in the Christian world, though the latter also remarks that, in consequence of the subject of which it treats, it was deemed by some in his day unworthy of a place in the canon. The Epistle to Philemon is one of the shortest portions of the Bible, containing only one chapter. It was written during Paul's imprisonment at Rome. After the usual introductory salutations, the apostle alludes to the good reputation which Philemon as a Christian enjoyed, and to the joy which the knowledge of this afforded him. He then introduces the main subject of the epistle. Onesimus, a servant or slave (δοῦλος) of Philemon, who had run away from his master, probably after having committed a theft, had been converted by Paul at Rome, and was sent back by him to his master, who is entreated to receive him "not as a servant, but as a brother beloved." Paul then pledges himself to make good any loss that Philemon may have suffered either through the dishonesty of Onesimus or through the want of his service; he requests Philemon to prepare him a lodging, as he trusted soon to visit him; and concludes with the salutations of some of his fellow laborers at Rome. The Epistle to Philemon has of late challenged in American theology particular study and comment, on account of its supposed bearing on the question of the relation of Christianity to slavery; and a number of religious organs in those states where African slavery exists have contested the correctness of the rendering of the Greek δοῦλος by "servant" in the common English version and in the new version of the American Bible union, insisting that "slave" would be the only correct rendering.—Of the life of Philemon nothing else is known. According to an ancient tradition, Appia, who is mentioned in verse 2, was his wife, and Archippus (in the same verse) his son. According to the Apostolical Constitutions he was bishop of Colossæ. The Roman Catholic church commemorates him as a saint on Nov. 22.

PHILIDOR. See DANICAN.

PHILIP II., the 18th king of Macedon, counting from Caranus, born in 382 B. C., assassinated at Ægæ in Aug. 336. The accounts of his early life are in many respects contradictory. He was the youngest son of Amyntas II. and Eurydice, and in 368 was given up by Ptolemy, then regent of Macedon, as a hostage to Pelopidas, who had marched into that country at the head of a Theban army. At Thebes Philip remained 2 or 3 years in the house of Pammenes, one of the principal citizens, and during his residence there undoubtedly acquired an intimate acquaintance with the strategetic art in its then most advanced state. When his brother Perdiccas had slain Ptolemy Alorites and had ascended the throne, he presented Philip, upon the advice of the philosopher Plato, with the government of a subordinate district. In 360 Perdiccas was slain in a battle with the Illyrians, and left the government in a distracted state. Beside the infant son of Perdiccas, the legal heir to the throne, there were claiming it his three half brothers, Archelaus, Aridæus, and Menelaus Pausanias, aided by a Thracian prince, and Argæus, assisted by the Athenians. Moreover, the country was threatened by incursions from the neighboring warlike tribes of Illyrians, Thracians, and Pæonians. Philip at first took charge of the government for his nephew Amyntas, but shortly after, probably in 359, ascended the throne himself, and immediately took vigorous measures to relieve himself from the difficulties by which he was environed. One of his half brothers he put to death; the other two saved themselves by flight. The Illyrians were bought off with presents and promises. The Athenians he contrived to detach to all intents and purposes from the support of Argæus, by withdrawing his garrison from Amphipolis, and declaring it a free city; and when that leader returned from his unsuccessful march upon Ægæ he was met at Methone by Philip and completely routed. The Athenian prisoners taken in the battle were treated with lenity and sent home, and these prudent measures, together with his pacific overtures, led to a treaty of peace between him and that people. Turning now his attention to nearer enemies, he subdued Pæonia, and in the same campaign reduced Illyria as far as Lake Lychnitis. These operations had taken up two years, and Philip, having freed himself from all danger of attack, began to act on the offensive. In 358 he commenced the siege of Amphipolis; and when ambassadors from that city implored the aid of the Athenians, their efforts were counteracted by the Macedonian envoys, who promised that the place if taken should be given up to Athens. Amphipolis fell, and Philip thus secured a convenient maritime port, commanding the country east of the Strymon, and in particular the gold region near Mt. Pangæus. The Athenians he continued to deceive with the promise of surrendering the city into their hands; and when the Olynthians, who now began to dread his growing power, sent embassies to Athens proposing an alliance, his partisans succeeded in having their proposals rejected. But while Athens was engaged in the sacred war, he suddenly formed an alliance with the Olynthians, and ceded to them Anthemus and Potidæa, the latter of which he had reduced. He had previously captured Pydna for himself, and although the siege of these places lasted long enough for aid to arrive from Athens, none came. Extending his conquests east of the Strymon, he took possession of the mining country opposite Thasos, and enlarged the city of Crenides, changing its name to Philippi. In the summer of 356, not long after the taking of Potidæa, three messages with good news reached Philip at once, informing him of the birth of his son Alexander, the defeat of the Illyrians by his general Parmenio, and the victory of one of his horses in the Olympic games. For a time he now laid aside active operations, but in 354 and 353 he began the siege of Methone, the only possession which Athens now held on the Thermaic gulf. After a vigorous defence the city at last surrendered, and Philip, master of this port, extended his incursions into Thrace, marching as far as Maronea, where he entered into negotiations against Athens with the Thracian prince Cersobleptes. He also threatened the Athenian possessions in the Chersonese, but was unable to reach them on account of the hostility of Amadocus, another Thracian prince. Turning his attention to Thessaly, he marched to the assistance of the Aleuadæ of Larissa against Lycophron, the tyrant of Pheræ; and the latter, unable to withstand the Macedonians, implored the aid of Onomarchus, leader of the Phocians, who sent into Thessaly his brother Phayllus with 7,000 men. Philip however defeated and drove him out of the country, whereupon Onomarchus, taking the field in person, marched into Thessaly, and routed the Macedonians in two battles, and with a loss so great that they were forced to withdraw into their own territory. After considerable difficulty in reviving the courage and devotion of his soldiers, Philip marched again into Thessaly, and, at the head of an army of 20,000 foot and 3,000 horse, signally defeated Onomarchus on the southern coast. He followed up this victory by the capture of Pheræ, which he made a free city, and of the maritime station of Pagasæ. He had on his march into Thessaly proclaimed himself the avenger of the Delphian god, and before the battle had decorated his soldiers with laurel wreaths. He now pushed on to the Phocian territory under the pretext of punishing the sacrilegious robbery of Delphi; but his entrance into that country was prevented by the Athenians, who guarded the pass of Thermopylæ. He now advanced toward the Chersonese, and began the siege of Heræum Teichos. The Athenians, alarmed by his rapid progress, made immediate efforts to equip a fleet for the defence of their possessions in that vicinity, but on a false report of his death they allowed their military operations to languish. About this time Demosthenes delivered his first philippic. Meanwhile the Olynthians, who had formerly been allies of Philip, now began to fear his power, and concluded a treaty with Athens about 352. No offensive operations on his part seem to have been begun until the middle of 350, when he seriously set to work to reduce the whole peninsula of Chalcidice, the pretext for the war against Olynthus being that his two half brothers had obtained a refuge in that city. The success of his arms in the peninsula was gradual but certain. City after city yielded to his power or was betrayed into his hands; and at last, master of Chalcidice, he marched directly against Olynthus and its two confederates, Apollonia and the Thracian Methone. Near the last named place he was wounded and lost the sight of one eye. Athens sent an expedition to the assistance of its ally, but the reënforcements were not sufficient to avail against the arts and arms of Philip. Olynthus was taken, probably early in the spring of

347, nearly as much by the use of money as by actual military strength. The inhabitants were sold into slavery, and Olynthus itself and the other cities of Chalcidice, 32 in all, were dismantled, and so thoroughly ruined that, according to a speech of Demosthenes 5 years later, their very sites were scarcely discernible. Athens now made a vigorous effort to unite the states of Greece in a common league against Macedon; but failing of much success, she listened to the overtures of peace which Philip indirectly offered. Negotiations were opened, which were skilfully protracted by Philip so as to subserve his own interests. The first embassy left Athens about Dec. 347, and returned about the beginning of March, bringing back a letter professing the most friendly feelings, but insisting as a condition of peace that each party should retain what it possessed. The treaty was adopted at Athens. But a dispute arose on the question of who were the allies included in the terms of the peace, the envoys of Philip refusing to acknowledge the Phocians as such. Before the second embassy reached him, he had conquered Cersobleptes, the Thracian prince and ally of Athens. The ratification of the treaty he delayed under various pretexts until he was at Pheræ, within 3 days' march of Thermopylæ. The Athenians, persuaded by Æschines and the other traitors of the Philippizing faction, did nothing for the defence of the pass. Phalæcus, the nephew and successor in command of Phayllus, thereupon concluded a convention with Philip, according to which he was to evacuate the territory with his mercenary soldiers, and with all Phocians disposed to accompany him; and the country fell immediately into the hands of the Macedonians. The amphictyons, assembling, invested Philip with the right of suffrage previously enjoyed by the Phocians, thus recognizing the Hellenic character of his nation; they moreover appointed him president of the Pythian games, which were held in Aug. 346, two months after the subjugation of Phocis. Athens, mortified and indignant at having been deceived and betrayed, was at first not disposed to concur in the vote giving him a place in the amphictyonic assembly, but was persuaded by Demosthenes not to display an anger at once dangerous and impotent. Master of Thermorpylæ, Philip now began his intrigues in the Peloponnesus, striving to excite the Messenians, Megalopolitans, and Argives against the Spartans. His active spirit was constantly at work throughout the whole of his dominions, confirming his authority in Thessaly, overrunning Pæonia and the Illyrian countries bordering upon Macedonia, and capturing cities on the Ambracian gulf. In 344 Athens, aroused by the eloquence of Demosthenes, sent embassies into the Peloponnesus to counteract his efforts, but they were attended with no success. Ill feeling prevailed between the Athenians and Macedonians for a long time before it broke out into open war. Philip began the siege of Perinthus in 340, but an Athenian fleet compelled him to retire; and a similar attempt to capture Byzantium failed in consequence of the presence of a fleet under Phocion, who moreover gained several advantages over him in land and naval actions. Philip therefore made peace with the Byzantines, withdrew his forces from that part of the country, and in the spring of 339 made a successful land expedition against the Scythian king Atheas; but on his return he was attacked by the Triballi, a Thracian tribe, defeated with the loss of his booty, and received a severe wound in his thigh. But about this time the amphictyons brought a new war into Greece, by resolving that the Amphissian Locrians, who had settled on the Cirrhæan plain, consecrated to the Delphian god, were to be punished for impiety. Philip was called in to execute the decree. He immediately began the march southward, and on his passage through Phocis seized Elatea and commenced refortifying that town. He declared his purpose to invade Attica, and sent envoys to Thebes, where a strong feeling against Athens prevailed, asking her assistance, or at least that a free passage through Bœotia should be granted. By the eloquence of Demosthenes, Thebes was persuaded to enter into an alliance with Athens, and the allied forces kept the field against Philip during the autumn and winter of 339 and 338, and gained over him several advantages. In Aug. 338, the battle of Chæronea was fought, in which Philip was signally victorious. The conquered Thebans he treated with severity, but motives of policy led him to adopt mild measures in regard to the Athenians, between whom and himself the treaty called the peace of Demades was negotiated, by which the Athenians recognized Philip as the head of Greece, and thus the great object of his ambition was secured. He now carried his arms into the Peloponnesus, and reduced the entire country, with the exception of Sparta, which it seems he did not attack. He held a congress of Grecian cities at Corinth, in which he unfolded his design of invading the Persian empire, and liberating the Asiatic Greeks. The congress voted him the leader of the Greeks, and decreed that the various states should furnish contingents. During 337 his preparations for the expected invasion went steadily on, and early in 336 a body of troops under Attalus and Parmenio was sent over into Asia. Not long before he had repudiated his wife Olympias, the mother of Alexander, on the ground of infidelity, and had married Cleopatra, the niece of Attalus. At the wedding banquet, incensed by a remark of Alexander, he tried to slay him, but, overcome by passion and drunkenness, fell to the floor. Alexander hereupon exclaimed: "Here is a man preparing to cross from Europe into Asia, who yet cannot step surely from one couch to another." He subsequently conducted his mother to her brother Alexander, king of Epirus. Afterward a reconciliation was effested between him and his father. To retain the good will of the king of Epirus while he himself was in Asia, Philip gave him his daughter in marriage; and festivities of great splendor were celebrated at Ægæ in Macedonia. Among the members of his body guard was a noble youth named Pausanias, who had in vain implored Philip to avenge an outrage committed by Attalus. Indignant at his failure, his hatred turned against his king, and his determination to assassinate him is said to have been encouraged by Olympias. As Philip was entering the theatre, Pausanias rushed forward and thrust a sword through his breast, killing him almost instantly. The assassin attempted to escape, but was overtaken and slain on the spot.—Philip was a man of great courage and activity, possessing military and diplomatic talents of the highest order. "Singularly fortunate, throughout the whole of his life, in being opposed to no great military leaders, he extended his conquests as much by corruption as by arms. He was of a strongly sensual temperament, as is evident from the number of his wives and concubines, was unscrupulous in his dealings, and careless of his promises. His patronage of literature and science was liberal. In addition to a manly presence and a powerful frame, he had a "ready eloquence, to which art only applied the cultivation requisite to satisfy the fastidious demands of a rhetorical age; quickness of observation, acuteness of discernment, presence of mind, fertility of invention, and dexterity in the management of men and things."

PHILIP V., king of Macedon, son of Demetrius II., born in 237 B. C., died in 179. His father died when he was 8 years old, but he did not succeed to the throne until the death of his uncle Antigonus Doson in 220. In the first year of his reign he was brought into the war then raging between the Ætolians and the Achæan league. Marching to Corinth with an army for the support of the latter, he presided over an assembly of the allied states in which war was declared against the Ætolians, and in the spring of 219 entered Epirus, but quickly returned to repel an invasion of the Dardanians. At the close of the year he suddenly showed himself in the Peloponnesus, and in a short campaign defeated an Ætolian and Elean army under Euripidas, captured Psophis, ravaged the Elean plain, and conquered Triphylia. In 218 he suddenly passed over into Ætolia, and took Thermus, the capital of that country, with all its treasures; and then, turning to the Peloponnesus, ravaged Laconia and defeated the Spartans under Lycurgus. The next year he captured Bylazora in Pæonia, and reduced the Phthiotic Thebes in Thessaly, but finally concluded a peace by which it was agreed that each party should retain what it possessed. At this time Philip began to turn his attention to the war then waged in Italy by Hannibal, and after the battle of Cannæ sent a messenger to conclude an alliance with the Carthaginian leader; but owing to the ambassador being intercepted by the Romans, the treaty was not made until 215. In 214 his fleet appeared in the Adriatic, took Oricus and laid siege to Apollonia, but was obliged to retreat on the arrival of a Roman force under Lævinus. The next year, however, he took Lissus and reduced the greater portion of Illyria. Meanwhile the character of Philip seemed to suffer a great change. In the beginning of his reign he had not only manifested military talents of a high order, but had been so distinguished for his moderation and generosity that the cities of Crete had placed themselves of their own accord under his protection. But now he broke with Aratus, his former friend and counsellor, and in 214 ravaged Messenia with fire and sword. In 211 an alliance was entered into against him by the Romans, the Ætolians, Scerdilaidas, king of Illyria, and Attalus, king of Pergamus. The war began in 210 and lasted until 205; and upon the whole Philip was successful, as the Romans were too much engaged with their Carthaginian war to render much assistance to their allies. The terms of the treaty were not much respected by the Macedonian king, who formed an alliance with Antiochus against Egypt; and having inflicted several injuries on the Rhodians, he became involved in a war with that people and Attalus. While besieging Chios, he was attacked and defeated by the combined fleet; but in another engagement off Lade, he was successful. The allies however equipping another fleet, it was with some difficulty that Philip was able to pass over into Europe in the spring of 200. The Romans, now free from their war with Carthage, listened to the complaints of the Rhodians, Attalus, and the king of Egypt, and declared war against Macedon. The contest was carried on until 196, at first somewhat to the advantage of Philip. In 200 he invaded Thrace, took Ænus and Maronea, penetrated into the Chersonese, captured Abydos, and returning entered Attica, nearly surprising Athens; but being foiled in this, he laid waste the country around the city. The following year he defeated the Ætolians, who had joined the Romans. The arrival of Titus Quintius Flamininus to take the command of the Roman army soon changed the aspect of affairs. A battle was fought in 197 at Cynoscephalæ in Thessaly, in which the Macedonians were defeated with a loss of 8,000 men killed and 5,000 taken prisoners. A peace was concluded in 196, according to the terms of which Philip was required to give up all his conquests in Europe and Asia, surrender his fleet to the Romans, reduce his standing army to 5,000 men, and pay the sum of 1,000 talents. One of the hostages for the fulfilment of these terms was his son Demetrius. Philip now acted outwardly as a zealous ally of the Romans, assisted them in their war against Nabis, king of Sparta, and subsequently not only refused to join Antiochus, but aided the Romans in their war with that monarch. So thoroughly were they satisfied with his conduct, that the portion of the fine unpaid was remitted, and his son Demetrius was sent home. But after the defeat of Antiochus they grew jealous of Philip, who was strengthening his power in every quarter. He was compelled to give up all his conquests in Perrhæbia and Thessaly, remove his garrisons from the cities of Thrace, and restrict his authority to the ancient boundaries of Macedonia. Demetrius was sent to Rome, and was received with so much favor and procured such advantageous terms that the jealousy of his brother Perseus was excited. The life of Philip was henceforth embittered by the dissensions between his two sons. In his domestic administration he also became more cruel, while he was engaged in secret preparations for renewing the war against the Romans. In an expedition into Pæonia, Perseus by means of forged letters succeeded in inducing his father to put Demetrius to death. The unhappy king was now overcome with grief and remorse, which were increased when he found that he had been deceived. He thought that he was haunted by the avenging spirit of Demetrius, and not long after died, in his last moments cursing his son Perseus.—Polybius said of Philip, that there were few monarchs of whom more good or more evil could justly be spoken. The early age at which he ascended the throne thwarted the development of his naturally good qualities, so that during the latter years of his reign he became tyrannical, perfidious, and cruel. In conversation he was a ready speaker, and possessed great power of repartee. In private life he was exceedingly licentious and fond of excessive drinking.

PHILIP II. Augustus, king of France, the 7th monarch of the Capetian line, born Aug. 22, 1165, died in Mantes, July 14, 1223. He was the son of Louis VII., was crowned at Rheims during the lifetime of his father, whom he succeeded in the following year (1180). His marriage with the daughter of the count of Hainault united the races of Capet and Charlemagne, and a second coronation was performed at St. Denis. He immediately banished all the Jews, confiscated their property, and persecuted the Waldenses. When his wife died without issue, the count of Flanders, her uncle, refused to give up Amiens, a part of her dowry, and a war broke out, in the course of which the count marched to the gates of Paris (1184). Philip, however, ultimately secured Amiens and nearly all of Vermandois. He was next involved in a war with the duke of Burgundy, who disputed his authority, and with Henry II. of England, whose sons he supported against their father. In 1188, on hearing of the fall of Jerusalem, he assumed the cross, and in 1190 the allied forces of France and England started on the third crusade. They reached the Holy Land in 1191, but, outshone by his rival Richard I., Philip soon returned to Europe, swearing on his departure to respect the dominions of the English king. Nevertheless, he soon found a pretext for invading Normandy, and made some conquests, while Richard was a prisoner in the hands of the emperor of Germany; but in 1194 he was repulsed from Rouen. After Richard's release a war, marked by no great military or political events, began between the two monarchs, and lasted till the death of Richard in 1199. The statesmanship of Philip in the end proved too much for the more soldierly qualities of the English king. During this war Philip recalled the Jews, being in need of money. Having divorced his second wife, and, in defiance of a papal bull, married in 1196 Agnes of Meran, a princess of the Tyrol, he was excommunicated, and his kingdom laid under an interdict. The death of Agnes of Meran enabled him to reconcile himself with the church, and the murder of Arthur by King John afforded him a plausible pretext for renewing the war with England. He summoned John to appear at his court and answer for the crime, and on his failing to do so adjudged him guilty of felony, and declared his dominions confiscated. Normandy was conquered in 1203, and Maine and Anjou soon afterward; and though Poitou and Guienne were not effectually subdued until the reign of Philip's son, the power of the English was broken. In Oct. 1206, a truce of two years was concluded, which Philip employed in strengthening his power, and developing the material resources of his dominions. About this time the crusade against the Albigenses began in the south of France, where the king scarcely exercised even nominal authority. Its early success encouraged the pope to excommunicate John, with whom a dispute had arisen, and to present England to Philip. Immense preparations were made for an invasion, but the French king was diverted from the execution of his purpose by the insubordination of Ferdinand, count of Flanders. He invaded the dominions of his vassal in 1213, and committed great ravages; but his fleet was defeated and destroyed at Dam by the English, under command of the count of Boulogne and the earl of Salisbury. The next year he was attacked on the side of Poitou by John, and on the side of Flanders by the nobles of the Low Countries commanded by Otho, emperor of Germany. John was beaten off by the dauphin Louis, and Otho was defeated in the battle of Bovines between Lille and Tournay, in which the counts of Boulogne and of Flanders were taken prisoners. After this the life of Philip is marked by no events of great military importance, except the expedition of his son Louis to England, to take possession of the crown of that country, to which he had been invited by a portion of the barons. Louis became master of nearly all the south, but in 1221 was obliged to leave the country. Philip himself took little interest in the military expeditions in which his son afterward engaged, devoting himself chiefly to the civil administration and the management of his revenues, amassing great wealth, which he divided among several legatees. He was the ablest king that had sat on the throne of France since the time of Charlemagne. The kingdom, limited at his accession to the Île de France and portions of Picardy and Orléanais, included in 1206 in addition all or nearly all of Vermandois, Artois, the Vexin-Français and the Vexin-Normand, Berri, Normandy, Maine, Anjou, Touraine, Poitou, and Auvergne. But it was less as a soldier than as an administrator that he was distinguished. He succeeded in part in establishing a central power by assembling about him a parliament of his grand vassals, of which he himself as suzerain was the head. He was still more successful in his efforts to free royalty from the power either of the pope or of the national clergy. In 1209 he seized the domains of the bishops of Orléans and Auxerre, who had refused their contingent dues for the fiefs they held, and, in spite of a papal interdict, compelled the prelates to admit his claim. He caused the streets of Paris to be paved, extended and heightened the walls, constructed numerous public buildings, conferred its chief privileges upon the university of Paris, and walled in and strengthened the principal towns of his kingdom. He favored the rights of the communes in the municipal towns, and his popular policy led them to prefer the government of the crown to that of their feudal lords. Under him royal power connected itself with social and material progress, and the French people made rapid advances toward consolidation into one nation.

PHILIP IV., the Fair, the 11th king of France of the Capetian line, born at Fontainebleau in 1268, died there, Nov. 29, 1314. He succeeded his father, Philip the Hardy, in Oct. 1285, and was crowned at Rheims in Jan. 1286. The beginning of his reign was disturbed by the war with Aragon begun in 1283, but this was speedily settled. He had long been meditating the invasion of Guienne, then held by Edward I. of England, when in 1292 a sort of piratical war waged between the sailors of the cinque ports and France gave him a pretext for summoning that monarch before the parliament of Paris. The English king, acknowledging the suzerainty of Philip, but detained by his contests with the Welsh and Scotch, sent his brother Edmund with full powers of negotiation; and this credulous prince was so outwitted through a fictitious treaty, that the surrender of all the fortresses in Guienne was procured. Philip then charged Edward with contumacy for not appearing in person, and declared his fiefs confiscated. The latter formed an alliance with the German emperor, Adolphus of Nassau, and the count of Flanders. A truce was however agreed upon, by the terms of which the question of Guienne was referred to the decision of the pope. In 1299 Flanders, which had not been included in the treaty, was reduced, and its count enticed to Paris and imprisoned. The dominions of Philip were now nearly equal to those of France in subsequent centuries. He engaged in a quarrel with Pope Boniface VIII., and in 1302 summoned a meeting of the states-general, in which it has been stated, but erroneously, that the *tiers état* were for the first time recognized. A rebellion broke out in Flanders, and in attempting to suppress it the French were defeated with terrible slaughter at Courtrai, July 11, 1302. The next year Philip marched into the Flemish territory at the head of a large army, but was unable to effect any thing; and about this time the expulsion of the French garrison from Bordeaux led to the restoration of Guienne to England (1303), and to a treaty of peace between the two crowns. In the mean while, his quarrel with the pope continuing, Philip summoned a meeting of the prelates and nobles, and accused Boniface of heresy, simony, sorcery, sensuality, and disbelief in the eucharist and in the immortality of the soul. An appeal to a general council was adopted. But Philip, trusting more to force than to pacific measures, sent into Italy William of Nogaret, who by the aid of the Colonnas made the pope prisoner; and although Boniface was released by a rising of the people, he shortly afterward died, probably from ill usage. He was succeeded by Benedict XI., who did not live long, and in turn was succeeded by Clement V., a pontiff wholly in the French interest, who transferred the papal residence to Avignon. Philip now prosecuted his Flemish war with fresh vigor, but little success, and a treaty of peace was finally concluded in 1305, by which the independence of Flanders was partially recognized. Actuated, it is supposed, by want of money, which had previously led him to persecute the Jews and depreciate the coinage, Philip next resolved to suppress the order of the templars. Charges of the most serious nature were brought against the body, and in Oct. 1307, all the knights of the order were arrested on the same night. Condemned by diocesan tribunals, numbers of them were burned, and others, who through fear of torture or death had confessed, were sentenced to minor punishments. To sanction the suppression of the order, the council of Vienne assembled in Oct. 1311, and in the spring of 1312 the pope pronounced it dissolved, and its property made over to the hospitallers. It did not however prove a very valuable endowment, the exactions and claims of the king's officers in the sequestrations being so enormous that the crown absorbed the greater portion of it. In 1314 two leading officers of the templars, Guy of Auvergne and the grand master Jacques de Molay, were burned for recanting their confessions; and on this occasion, it is said, the grand master summoned the pope and the king to appear before the judgment seat of God, the former within 40 days, the latter within a year and a day. Whether this summons was real or imaginary, both sovereigns died within the specified periods. The last years of Philip's life were taken up with the collection of taxes, and prosecutions and executions for political offences. In 1313 the wives of his three sons were charged with adultery; one of them was sentenced to perpetual imprisonment, and one, Margaret of Burgundy, wife of his eldest son Louis, was strangled in prison, while the third was acquitted. Involved in new difficulties with the Flemings, he was obliged by an insurrection of his own people to make a compromise with them. During his whole reign he was governed by the legists, who steadily strove for the overthrow of the feudal system, and to strengthen and render independent the royal authority. His power was of the most despotic character, and there was often much disaffection among the people in consequence of the enormous taxes and debasement of the coinage.

PHILIP VI. OF VALOIS, the 15th king of France of the Capetian line, and first of the house of Valois, born in 1293, died in Nogent-le-Roi, near Chartres, Aug. 22, 1350. He was the son of Charles of Valois, brother of Philip the Fair, and during the reign of Philip the Long headed an unsuccessful expedition against the Ghibelline party in Lombardy. On the death of Charles the Fair in 1328 without a male heir, though his widow was pregnant, Philip was intrusted with the regency. When the queen was delivered of a daughter, who was excluded by the Salic law from the throne, the right to the succession became a matter of dispute; but at last it was settled on Philip, who was crowned at Rheims, May 29, 1328. The same year he undertook an expedition against the Flemings, whom he defeated with considerable loss, and took the city of Cassel. The next few years were occupied in the civil administration of France, regulating the currency, settling disputed boundaries, and especally in determining the claims of Robert, count of Beaumont, to Artois. The pretensions of Robert were not admitted, and that prince, banished from the realm in 1330, took refuge in England. Philip entertained the project of a crusade against the Moors of Granada, but the demands he made of the pope were so exorbitant, that the matter came to nothing. In the mean while the assistance which he rendered to Robert Bruce, king of Scotland, irritated Edward III. of England, who claimed to be the heir of the French throne, and a war broke out in 1337, Edward forming an alliance with the Flemish burghers under James Artevelde. This war, which lasted through the reign of Philip, proved most disastrous to the French. In 1342 Philip issued an ordinance making salt a government monopoly. In Aug. 1346, Philip was defeated at Crécy by Edward III., who took Calais the next year. In 1348 the ravages of the plague prevented a general renewal of the war. Philip was somewhat compensated for his losses both from war and disease by the addition to the French dominions of the province of Dauphiné. In 1350 he espoused the princess Blanche of Navarre, but soon after died. He was succeeded by his son John II.

PHILIP II., king of Spain, born in Valladolid, May 21, 1527, died at the palace of the Escurial, Sept. 13, 1598. His father was Charles V., emperor of Germany and king of Spain, and his mother the empress Isabella, daughter of Emanuel the Great of Portugal. He was carefully educated, and showed some taste for science and the fine arts, especially for mathematics and architecture. Even in childhood he was thoughtful, cautious, and reserved. His father kept him surrounded by able statesmen, who early familiarized him with ideas of government. At the age of 16 he was married to his cousin the infanta Maria, daughter of John III. of Portugal, who died within two years, a few days after giving birth to the celebrated and unhappy Don Carlos. Philip was married a second time, July 25, 1554, at Winchester, to Mary, queen of England, with whom his father had negotiated the match. To make the husband equal to the wife in rank, Charles resigned to his son the kingdom of Naples and the duchy of Milan. The marriage was not a happy one, for Mary was very ugly, and Philip, though she doated on him with the most passionate fondness, treated her with coldness and was notorious for his infidelities. After a residence of somewhat more than a year in England, he was summoned to Flanders by his father, and in Sept. 1555, reached Brussels, where on Oct. 25 was fulfilled the famous act of abdication by which Charles transferred to Philip the sovereignty of the 17 provinces of the Netherlands. Three months later, Jan. 16, 1556, the emperor also ceded to his son all his remaining hereditary dominions, and shortly afterward resigned the elective crown of the German empire in favor of his brother Ferdinand. By his father's abdication Philip thus became sovereign of the most powerful and extensive empire in the world, including, beside the Netherlands, a great part of Italy, the whole of Spain, and the vast Spanish possessions in America, Africa, and the East Indies. He is described at this time as a small, meagre man, much below the middle height, with thin legs, a narrow chest, and the shrinking, timid air of a habitual invalid. He had a heavy, hanging lip, with a vast mouth and monstrously protruding lower jaw. His complexion was fair, his hair light and thin, his beard yellow, short, and pointed. He had the face of a Fleming with the manners of a Spaniard. He looked constantly on the ground when he conversed, was chary of speech, embarrassed and even suffering in manner. "This was ascribed," says Motley, "partly to a natural haughtiness which he had occasionally endeavored to overcome, and partly to habitual pains in the stomach occasioned by his inordinate fondness for pastry." He was considered by his contemporaries at that period to be sluggish in character and deficient in mental capacity. He had, however, an inclination for business amounting almost to a passion, and was an indefatigable writer of despatches, spending nearly all his time in his cabinet with his ministers and secretaries. His main object in life was to support and advance the Roman Catholic religion, of which he was a most devoted adherent. His ambition for the aggrandizement of his empire was always subordinate to his concern for the church; and he was accustomed to say: "Better not reign at all than reign over heretics." But although his piety and his position at the head of the Roman Catholic princes of Europe made him the natural ally of the pope, one of the first events of his reign was a war with Paul IV., who then occupied the papal throne. The pope had formed an alliance with Henry II. of France and with Solyman the Turkish sultan, the latter of whom agreed to make a descent on the Italian dominions of Philip, while a powerful French army led by the duke of Guise entered Italy for the conquest of Milan and Naples. Philip had intrusted the government and defence of the latter kingdom to the duke of Alva, and that able and experienced soldier in one campaign carried his arms to the walls of Rome, and in another drove the French out of Naples and compelled the pope to sue for peace, which was concluded Sept. 14, 1557. Meantime Philip in person was vigorously prosecuting hostilities in the northern provinces of France, having by his influence with Mary induced England to declare war against that country. Under his direction a powerful army, the actual commander of which was Emanuel Philibert, duke of Savoy, assisted by William of Orange, Egmont, and other officers of distinction, entered Picardy and laid siege to St. Quentin. A French army commanded by the constable de Montmorency, attempting to relieve the place, was defeated, chiefly by the brilliant valor of Egmont, in a decisive battle fought Aug. 10, 1557, the day of St. Lawrence; and in honor of that martyr, to whose interposition he ascribed the victory, Philip subsequently built the convent and palace of the Escurial. Two thirds of the French army were killed or taken prisoners. The town of St. Quentin soon after the battle was taken by storm. Other victories over the French rapidly succeeded, but the jealousies of his English and German allies prevented Philip from pressing his conquests by marching on Paris. In the following year the French under Marshal Termes invaded Flanders, and were signally defeated in the battle of Gravelines by a Spanish and Flemish army commanded by Egmont, who much enhanced by this achievement the reputation he had gained in the campaign before St. Quentin. These defeats induced the French king to accede to terms of peace, which were finally settled (April 2) by the treaty of Câteau Cambrésis, which was highly favorable to Philip and greatly raised his reputation in Europe as a sovereign and as a diplomatist. While negotiations were going on his wife Mary of England died, Nov. 17, 1558. Very soon after her death Philip made offers of marriage to her successor Queen Elizabeth, which were rejected. Philip did not take the refusal greatly to heart, and speedily sought and obtained the hand of the princess Elizabeth, or Isabella, daughter of Henry II. of France, who at the late treaty had been promised to Philip's son Carlos, for whom in years she was a much more suitable match than for his father, the prince and the princess being at that time both about 14. The marriage was celebrated at Paris, June 24, 1559, the duke of Alva acting as his sovereign's proxy. A few weeks later Philip sailed from the Netherlands to Spain, where he afterward always resided, and where he was joined by his bride early in the following year. He left the government of the Netherlands in the hands of his half sister Margaret, duchess of Parma, as regent, assisted by a council composed in part of William of Orange, Count Egmont, and Antoine Perrenot, bishop of Arras, subsequently better known as Cardinal Granvelle. Philip had not been many days in Valladolid, where the court then resided, Madrid not being made the capital till 1562, before he signalized his devotion to the church by attending an *auto de fé*, at which by order of the inquisition 14 Protestants were burned at the stake, two of them men of high rank and distinguished talents, Don Carlos de Seso and Don Domingo de Roxas. As the victims were led past the gallery in which the royal family sat to witness the spectacle, De Seso called out to Philip: "Is it thus that you allow your innocent subjects to be persecuted?" Philip replied: "If it were my own son, I would fetch the wood to burn him were he as wicked as thou art." In this spirit, soon after his return to Spain, Philip began to take measures for extirpating heresy in the Netherlands, where the doctrines of the reformation had already made great progress. For this purpose he had in conjunction with the pope added 14 new bishoprics to the 4 already existing in these provinces. This step caused great excitement among the Netherlanders, who looked upon it as but the prelude to the overthrow of all their rights and privileges and their complete subjection to the inquisition, which had already crushed Protestantism in Spain, and was now busily at work among themselves. The popular opposition to this and other measures of the Spanish court was led by Orange, Egmont, Horn, Montigny, and other eminent and influential nobles, some of whom were Catholics. Their energetic protests compelled Philip in 1564 to withdraw Granvelle from the country, the odium of these proceedings being popularly fixed on that prelate. The persecution of the Protestants was however continued, and in 1566 it is recorded that 17 were publicly burned at the stake. The people at length rose in insurrection, and in 1567 the cruel duke of Alva was sent with a powerful army to repress the rebellion and extirpate the heretics. Under the rule of this tyrant the most terrible barbarities were inflicted on the Protestants. Egmont and Horn and several other great nobles were arrested and beheaded, and during his administration of 6 years 18,000 persons perished on the scaffold, beside immense numbers put to death in battles, sieges, and massacres. This ferocity however failed to subdue the insurgents, who under the wise leadership of William of Orange maintained a heroic and generally successful struggle against Alva and his successors, Requesens, Don John of Austria, and the duke of Parma. In 1579 the seven United Provinces formed the union of Utrecht, and during the rest of Philip's reign maintained their independence and carried on a vigorous war with the Spaniards by land and sea. Among the remarkable incidents of this long contest was one strongly illustrative of Philip's character—the secret execution of the lord of Montigny, the younger brother of Count Horn. He was sent to Spain in 1566 by the nobles of the Netherlands as an envoy to the king to lay before him the real state of the provinces. Philip received him at first graciously, but detained him, and in Sept. 1567, committed him as a prisoner to the fortress of Segovia, and afterward to that of Simancas, where, in Oct. 1570, he was strangled in so secret a manner that his fate remained a mystery till a few years ago, when the opening of the archives of Simancas, in which the king's correspondence with his ministers had been deposited, disclosed the fact that Philip in his own handwriting had given the most minute directions for the murder and for its subsequent concealment by giving out that Montigny had died of a fever. The unfortunate nobleman, though he opposed the persecution of the Protestants, was a devout Catholic; and Philip, in communicating in a private despatch to Alva the real circumstances of his death, says: "If his inner man was penetrated with as Christian a spirit as he exhibited in the outer, and as the friar who confessed him has reported, God, we may presume, will have mercy on his soul." Another remarkable transaction, in which the personal agency and character of Philip may be clearly traced, was the assassination of William of Orange, the great leader of the revolt of the Netherlands. Against this eminent statesman and hero the king issued in 1580 a formal ban, declaring him an outlaw and an enemy to the human race: "And if any one of our subjects or any stranger shall be found sufficiently generous of heart to rid us of this pest, delivering him to us alive or dead, or taking his life, we will cause to be furnished to him, immediately after the deed shall have been done, the sum of 25,000 crowns in gold. If he have committed any crime, however heinous, we promise to pardon him; and if he be not already noble, we will ennoble him for his valor." Incited by this proclamation, various assassins attempted to kill the prince; and at length a Burgundian fanatic, Balthasar Gérard, having previously made known his design to the prince of Parma, who communicated it to Philip, murdered Orange at Delft, in 1584. Gérard was taken and put to death, but Philip rewarded his heirs with estates of great value and with patents of nobility. "Had it only been done two years earlier," said he on hearing of the murder, "much trouble might have been spared me; but 'tis better late than never." During the earlier part of the war with the Netherlands, Philip carried on almost constant hostilities against the Mohammedans. The famous siege of Malta by the Turks in 1565 was raised by his forces sent from Sicily. His persecution drove the Moors of Granada to a revolt in 1568, which was suppressed with rigorous barbarity. It was followed in 1571 by a war with the Turks, the principal event of which was the great naval victory of Lepanto, won by Philip's brother Don John of Austria, in which the Ottoman fleet was nearly annihilated. In 1578–'80, by the death of Dom Sebastian and of Henry the cardinal, the throne of Portugal became vacant, and Philip, as uncle of Sebastian, claimed the crown, and sent Alva with an army to enforce his right. This was successfully effected, and in 1581 Philip was recognized by the Portuguese estates as rightful sovereign of the kingdom. After the death of Orange, he bent all his energies and resources to the conquest of England, from which the Netherlands were continually receiving assistance in men and money. After long preparation the "invincible armada" was sent for this purpose in 1588, and was completely foiled and vanquished, partly by the elements, and partly by the English fleet commanded by Lord Howard, Sir Francis Drake, and other distinguished leaders. (See ARMADA.) Philip received the news of this terrible disaster with composure. "The will of God be done," he said; "I sent my ships to fight with the English and not with the elements." The relations of Philip with France during his long reign had been sometimes warlike and sometimes peaceful, but both his arms and his money were freely given to aid the Catholics of that kingdom against the Huguenots. He continued his hostility against Henry IV. even after that monarch had become a Catholic, and his intrigues led Henry in 1595 to declare war against him. The contest was not favorable to Spain, and in 1597 Philip was reluctantly compelled to consent to the peace of Vervins. In the next year a complication of distressing maladies, the consequence of early debaucheries, caused his death, which took place in the palace of the Escurial, which he had himself built, and which still remains the most magnificent monument of his power and wealth. One of the strangest transactions of Philip's reign was his treatment of his eldest son Don Carlos, which has frequently since afforded a favorite theme for historians, poets, and romancers. It was commonly believed until recently that the prince had been put to death by command of Philip, but the researches of Prescott and of other recent historians have shown that Don Carlos was probably insane, and that after vavious outrages on his father's friends and ministers he had formed the design of taking the king's life, and was consequently arrested and kept in confinement till he died about 6 months afterward of a fever brought on and heightened by the most extravagant recklessness of diet and exposure. Within 3 months after the death of Carlos his stepmother Queen Isabella died, it was reported at the time by poison administered by Philip's order. This calumny has also been refuted by recent researches, and it is now known that she died in giving birth to a daughter who did not survive her, and was buried in the same coffin. The queen died in 1568, and in 1570 Philip married as his fourth wife the archduchess Anne of Austria, daughter of the German emperor Maximilian II., who became the mother of his successor Philip III.—See Prescott's "History of Philip II." (3 vols., Boston, 1856–'9), and Motley's "Rise of the Dutch Republic" (3 vols., New York, 1856), and "History of the United Netherlands" (2 vols., New York, 1861).

PHILIP V., king of Spain, the first of the house of Bourbon in that country, born at Versailles, Dec. 19, 1683, died July 9, 1746. The 2d son of the dauphin Louis by Maria Anna of Bavaria, and a pupil of Fénelon, he was known as duke of Anjou until by the will of Charles II., who died childless, he was called to the throne of Spain, Oct. 2, 1700. In the following month he was declared king at Fontainebleau by his grandfather Louis XIV., and proclaimed at Madrid. His arrival in the peninsula was hailed with lively manifestations of popular satisfaction, while his power was acknowledged in the kingdom of Naples, Milan, the Netherlands, and the Spanish colonies of America. No opposition was offered to his accession by any European power except the house of Austria and the empire, who protested against the will of Charles II., and prepared for war. Philip nevertheless seemed to be firmly established, winning the favor of his subjects by attention to his duties, curtailment of useless offices, reform of abuses, and personal affability. But the rashness of Louis XIV., who, in contravention of express stipulations, endeavored to secure to his grandson the right of succession to the crown of France, alarmed Europe. A league between Austria, Holland, Great Britain, the empire, and Prussia was formed against France and Spain, to uphold the claims of the archduke Charles to the Spanish crown. The only allies of Philip V. at the opening of the contest were his uncle the elector of Bavaria, the duke of Savoy, whose daughter Louisa Maria Gabriella he had married, and the king of Portugal; but the last two were soon detached from his alliance by promises of territory, and finally joined the above coalition. The war opened in 1701 in Italy, where Prince Eugene at the head of Austrian troops gained the victories of Carpi and Chiari. Philip repaired to Italy in person and shared in the victory of Luzzara, Aug. 15, 1702, but was obliged to return in haste to Spain, which was attacked by the combined troops of Great Britain and Holland. The archduke landed in Portugal in 1704; and the king, marching against him, defeated the Portuguese on the frontiers, but was unable to retake Gibraltar, which had been captured by Admiral Rooke, Aug. 4, 1704. During 1705 the provinces of Valencia, Catalonia, and Aragon acknowledged the archduke, whom Philip unsuccessfully besieged in Barcelona. The disorganization of his army obliged him to retreat to Perpignan, but he soon reëntered Spain, and through Navarre and Old Castile returned to Madrid, where his presence was sorely needed. Scarcely had he reached the capital, however, when the approach of Lord Galway and the marquis of Las Minas forced him to retreat to Burgos, accompanied by a small band of faithful adherents; while the archduke, under protection of the English and the Portuguese, was proclaimed king with the title of Charles III. Philip's affairs were now so desperate that he was advised to emigrate to his American dominions; but, encouraged by his wife and the princess des Ursins, he refused to abandon the field, and rejected the overtures of peace that were made by his opponents. His constancy soon had its reward; supported by Marshal Berwick, whose skill and valor retrieved his fortunes, he reëntered Madrid after an absence of scarcely 9 months, and was reinstated on the throne by Berwick's brilliant victory at Almanza, April 25, 1707. The successful operations of the duke of Orleans in Valencia, Aragon, and Catalonia consolidated his power; but that commander, being charged by the princess des Ursins with views of personal aggrandizement, was recalled to France; and Philip's success in Spain was checked, while abroad he lost Sardinia and Port Mahon in 1708. In the campaign of 1709, however, Tortosa, Denia, and Alicante were taken by his troops; but in the following year the two victories of Count Stahremberg enabled Charles III. to return to Madrid, whence Philip had again to fly. The timely arrival of Vendôme from France gave another favorable turn to affairs, and in company with that brilliant general Philip boldly advanced to the capital, expelled his competitor, and reëntered it, Dec. 3, 1710. The decisive battle of Villaviciosa, fought Dec. 10, was the signal of his definite triumph. Catalonia and Aragon were reconquered, and the archduke having meanwhile by the death of his brother become emperor, the greatest obstacle to peace was removed, the European powers being unwilling to restore the vast monarchy of Charles V., and Philip V. on his part assenting (Nov. 5, 1712) to a formal renunciation of his claims to the French succession. By the treaty of Utrecht he remained master of the kingdom of Spain, Spanish America, and other colonies out of Europe; but he had to abandon Sicily to the duke of Savoy, and the Netherlands, Milan, and Sardinia to the house of Austria. Opposition at home was now quelled; and a treaty being signed with Portugal, Feb. 15, 1715, Philip was permitted to reign in peace for several years. The government had been heretofore mostly in the hands of the *camarera mayor*, the celebrated princess des Ursins, whom the queen had brought from France with her. This able woman had made and unmade ministers; she had assisted Orri in restoring the finances; she had even exercised her influence over the operations of war. The death of the queen, Feb. 14, 1714, seemed but to add to her power, and she so completely won the confidence of the king that it was rumored that she was to become his wife. By the advice however of Alberoni, she caused Philip to marry Elizabeth Farnese, whom she expected to govern as she had done her predecessor; but on her arrival Elizabeth unceremoniously banished the *camarera mayor* from Spain. Through her influence Alberoni was appointed prime minister (1716), and Spain seemed to be inspired with new life. Agriculture, commerce, and the arts revived; Sardinia and Sicily were reconquered, and Alberoni, rewarded with the dignity of cardinal, persuaded his master to undertake to restore the Stuarts in England by the assistance of Charles XII. of Sweden, to wrest the regency of France from the duke of Orleans, and to precipitate the Turks upon Austria. But, defeated in all these projects, Philip exiled the unsuccessful minister and joined the quadruple alliance, Feb. 17, 1720, giving up Sicily to Austria, while the duke of Savoy received Sardinia. He moreover, in 1721, abandoned Gibraltar and Port Mahon to the English, and by matrimonial alliances strengthened his union with France. His health had failed under his long trials; an invincible melancholy, aggravated by religious fears, preyed upon his mind; and, in spite of his wife's remonstrances, he abdicated, Jan. 10, 1724, in favor of his eldest son Louis, and retired to the monastery of San Ildefonso. But his son dying at the end of 8 months, he yielded to the entreaties of the queen and resumed the exercise of power, Sept. 6, 1724. Another change of policy now took place, and by the instigation of Ripperda, a Dutch adventurer, who had won the queen's favor, Philip entered into an alliance with the emperor Charles VI., by the treaty of Vienna, April 30, 1725, whereby the two sovereigns guaranteed each other's possessions, and the Spanish king promised to uphold the emperor's pragmatic sanction. The alliance proved far from advantageous. Philip made an unsuccessful attempt in 1727 to retake Gibraltar, and then becoming disgusted with Ripperda, whom he had made his prime minister, banished him from Spain, listened to proposals from Cardinal Fleury, sent plenipotentiaries to the congress at Soissons (1728), and finally signed with France and Great Britain the treaty of Seville, by which he obtained for Don Carlos, his elder son by Elizabeth, the reversion of the duchies of Tuscany Parma and Piacenza. He participated in the war for the succession of Poland (1733), and sent his son with the count of Montemar to Italy, where the latter, by his victory at Bitonto in 1735, conquered the kingdom of Naples, which was secured to the young prince by the treaty of Vienna (1738), while Tuscany was transferred to the duke of Lorraine, and Parma and Piacenza were assigned to the emperor. A dispute with England relating to American colonial affairs ended in hostilities, which were still going on when the war for the succession of Austria broke out. In this Philip, or rather his queen Elizabeth and her second son Philip, actively engaged; and the latter was in a fair way to win a kingdom in northern Italy when the king died. Notwithstanding his want of energy and enterprise, Philip's reign was upon the whole favorable to Spain; some useful reforms had taken place, especially in the administration of justice; the finances were managed with considerable regularity; the navy was restored to a state of efficiency; industry and commerce were fostered; and a royal library and academies of languages, history, and the fine arts were established. Philip had by his first wife two sons, viz.: Louis, who died after a reign of 8 months, and Ferdinand VI., his successor; by his 2d wife, Don Carlos, whom he left king of Naples, Philip, who became duke of Parma in 1748, and several daughters, 3 of whom married respectively Joseph, king of Portugal, Louis, dauphin of France, and Victor Amadeus III. of Savoy.

PHILIP I. and II. of Burgundy. See BURGUNDY.

PHILIP, one of the 12 apostles, born in Bethsaida, of which Peter and Andrew were also natives. Philip was the 4th of the apostles who attached themselves to the person of Jesus (John i. 43 *et seq.*), Andrew, John, and Peter having been called before him. The first act recorded of Philip is his bringing Nathanael to Jesus. When Christ fed the 5,000 people with five loaves and two fishes, he addressed to Philip the question: "Whence shall we buy bread that these may eat?" and it is added: "This he said to prove him, for he himself knew what he would do." (John vi. 1–7.) On another occasion Philip asked Jesus: "Lord, show us the Father, and it sufficeth us." (John xiv. 8.) From these two passages several of the fathers, as Chrysostom and Theodore of Mopsuestia, inferred that this apostle was weak in faith. In another place of the Gospel of John (xii. 20–22), we find that certain "Greeks" (proselytes of the gate) at Jerusalem, who wished to see Jesus, applied for that purpose to Philip, who, uncertain whether to comply with their wish or not, consulted Andrew, and both then went to tell Jesus. He is again mentioned in Acts i. 13, as being present with the other apostles at the religious assembly following the resurrection of Christ. According to Theodore he preached the gospel in Phrygia, according to others in Upper Asia, according to most in Scythia. All traditions agree that he met his death at Hierapolis in Syria. The Greek church commemorates him on Nov. 14, the Roman Catholic on May 1. A church at Rome claims to possess his body. Several apocryphal writings were ascribed to Philip; thus the Gnostics and Manichæans had an *Evangelium Philippi*, and the decree of Pope Gelasius denounces the forged "Acts of Philip."

PHILIP, King, sachem of Pokanoket, youngest son of Massasoit, and the successor in 1657 of his brother Alexander, killed Aug. 12, 1676. In 1662 he promised at Plymouth to continue the friendship heretofore existing with the English, to remain faithful to the king and colony, and not to dispose of any of his territory without giving them notice. In 1670–'71 rumors began to prevail that he was inclined to break the treaty. The tribe was frequently assembled, war preparations were constantly going on, and wanton murders were sometimes committed. The messengers from Massachusetts sent to mediate between the people of Plymouth and Philip held a meeting at Taunton, in which the latter renewed his covenant with his "ancient friends." But disregarding the condition, a new agreement was finally entered into, by which Philip admitted the superiority of the Plymouth government. For 3 years after this there was no disturbance, and it has been a doubtful point whether the storm which broke out so suddenly in 1675 was simply accidental in its origin, or the result of a real and deliberate plot. At any rate hostilities were precipitated by the rashness of some of the younger members of the tribe. Sassamon, a converted Indian who had informed the colony of the preparations going on, was killed. His murderers were tried, convicted, and executed, and in revenge the Indians murdered 8 or 9 white men. Philip thus became a rebel, although he is said to have wept when he heard that a white man's blood had been shed. The war was of the most desolating character, the Indians never meeting the enemy in the open field, but rapidly passing from one exposed point to another, burning villages, cutting off by ambuscades detached parties of troops, and shooting down every one who ventured to stray outside of the places of protection. Philip also formed an alliance with the powerful tribe of Narragansets, and in Dec. 1675, 1,000 men under the command of Josiah Winslow invaded their territory, stormed a fort in which there were said to have been 4,000 Indians, and utterly destroyed their village with all its stores. The war raged during the first half of 1676 with unabated fury, but the conquest of the Narragansets and the complete destruction of his own tribe soon left Philip without resources. Deserted by all, he was hunted from spot to spot, and at last, taking refuge at Mount Hope, was there attacked by a party under Capt. Church, and in attempting to flee was killed by an Indian. In this war 13 towns were completely destroyed and many others suffered severely; 600 buildings were burned, 600 of the colonists were slain, and the expenses were in the neighborhood of $500,000. The calamities of the war fell chiefly upon the Massachusetts and Plymouth colonies, Connecticut suffering comparatively little.

PHILIP, Pseudo. See Andriscus.

PHILIPPI, an ancient city in the E. extremity of Macedonia, enlarged by Philip, father of Alexander the Great, from whom it received its name. Previously it had been called Crenides, the "place of fountains," from the numerous streams in the neighborhood. Near it were gold mines, which were not very productive until worked by Philip, who obtained from them 1,000 talents a year. In 360 B. C. the city was in the hands of the Thracians, but was taken and fortified by the Macedonian monarch as a protection against the Thracian mountaineers. It was at Philippi that the battle between Brutus and Cassius on one side, and Antony and Octavius on the other, was fought in 42 B. C. There were two engagements on the same ground, 20 days apart, in the first of which Brutus gained the advantage over Octavius, and Antony over Cassius; but in the second the murderers of Cæsar were totally routed. Philippi was afterward made a Roman colony by Augustus. It was twice visited by Paul (Acts xvi. and xx.), and to the church founded there he addressed one of his epistles during his captivity at Rome. Subsequently Philippi became the ecclesiastical capital of Macedonia Prima, when that province was divided into two by Theodosius the Younger. It is now a mass of ruins, of which the chief are the remains of what appears to have been a palace, and of the acropolis, situated on a solitary height, and consisting of 3 towers and portions of walls.

PHILIPPIANS, Epistle to the, a canonical book of the New Testament, written, according to the unanimous testimony of the ancient church, by the apostle Paul. It is expressly referred to by Polycarp, by the churches of Vienne and Lyons in the 2d century, and by many of the earliest fathers. In modern times its authenticity has been doubted by Baur (*Paulus der Apostel Jesu Christi*, p. 458 *et seq.*), against whom it has been in particular defended by Lünemann (*Pauli ad Philippenses Epistolam contra Baurium defendit*, Göttingen, 1847). The epistle was probably written toward the close of the apostle's imprisonment at Rome. The occasion for it seems to have been given by a pecuniary contribution which the congregation at Philippi sent him through Epaphroditus (iv. 10-18). Epaphroditus was taken sick in Rome (ii. 27), and after his recovery was sent back with this epistle to the Philippians. The epistle may be divided into 3 parts. In the first (ch. i. and ii.) the apostle refers at length to his sufferings in Rome, which, however, fell out "rather unto the furtherance of the gospel." For this cause he declares himself willing to live and labor, though, as respected his personal feelings, he would "rather depart and be with Christ." He calls on the Philippians to maintain steadfastly their profession, and particularly urges union and humility. In the second part (ch. iii.) he warns them against the teachings of false Judaizing prophets, whom he calls dogs and evil workers. He shows that if Jewish descent and Jewish privileges were to go for any thing, no one could have stronger claims on this ground than himself; but he counts "all things but loss for the excellency of the knowledge of Jesus Christ," and he exhorts the Philippians to be likewise thus minded, and to strive after holiness. In the third part (ch. iv.) he addresses some exhortations to individual members, continues his general admonitions, refers again to his personal circumstances and to the aid received from the Philippians, and concludes with salutations and benedictions.—Good separate commentaries on this epistle have been written by Rheinwald (Berlin, 1827), Mathies (Greifswalde, 1835), Hölemann (Leipsic, 1839), Hengel (Amsterdam, 1839), Rilliet (Geneva, 1841), and in English by Pierce and Ferguson.

PHILIPPINE ISLANDS, a group of the Indian or Eastern archipelago, belonging chiefly to Spain, bounded N. and E. by the Pacific, S. by the seas of Celebes and Sooloo, and W. by the China sea; extending from lat. 5° 32′ to 19° 38′ N., and from long. 117° 21′ to 126° 8′ E.; area of the whole, about 200,000 sq. m.; pop. estimated at 5,000,000. The total number of islands is about 1,200, but the greater part are of little importance, being mere rocks. About 40 are of considerable size, and of these the principal are Luzon, Mindanao, Mindoro, Panay, Negros, Zebu, Bohol, Leyte, Samar, Masbate, and Palawan. Luzon is of very irregular shape, and consists of two portions connected by a narrow isthmus; its extreme length is 550 m., breadth 130 m.; area, 57,505 sq. m.; pop. 2,176,930. Mindanao is next in size to Luzon, and in shape somewhat resembles an isosceles triangle, measuring nearly 300 m. each way. Mindoro is about 110 m. long and 53 m. broad; Panay nearly 100 m. each way; Negros 130 m. long, with an average breadth of 25 m.; Zebu forms a narrow belt about 100 m. in length; Bohol is about 52 by 24 m.; Leyte 110 by 60; Samar 147 m. long with an average breadth of 50 m.; Masbate about 60 by 17 m.; and Palawan about 260 m. long with an average breadth of 40 m. In general characteristics all these islands bear a striking similitude. The coasts are much indented by arms of the sea stretching far into the land. A range of mountains traverses the entire group in a N. and S. direction, the summits of which seldom exceed 6,000 feet in height; many of them are extinct volcanoes, while some are still subject to dangerous eruptions. Among the mountains are many extensive valleys and plains, numerous marshes and bogs, and several lakes. Some of the rivers are of considerable size, and in conjunction with the arms of the sea that extend inland afford great facilities for internal communication. The geological formation consists of almost every kind of rock, but the structure is throughout volcanic. Gold is found in most of the larger islands, together with iron, copper, and lead, and mercury in Luzon. Sulphur is abundant, and coal has been worked to some extent on a small island off the E. coast of Luzon, and found in two places at the S. end of Mindanao. Carbonate of lime is very abundant, and marble is found in several places.—The climate is warm, and there is the same succession of seasons throughout the group as elsewhere in the Indian archipelago and upon the coasts of Hindostan. During the S. W. monsoon, from May to September, heavy rains fall upon the W. coasts, the low grounds become flooded, and violent storms are liable to happen, while the chain of mountains that traverse the group keep the weather on the E. shores serene and dry. The opposite monsoon, however, which begins to blow in October, brings similar weather on the E. coasts, keeps the climate constantly damp, and renders vegetation exceedingly luxuriant. The soil is remarkably fertile, and the principal productions of the group are rice, maize, cotton, sugar cane, coffee, cloves, pepper, indigo, hemp, tobacco, cacao, bananas, cocoanuts, and various other kinds of palms. Many tropical fruits and vegetables are grown, and the Spaniards have introduced several kinds from the temperate zones which have succeeded remarkably well. The mountains are covered with forests of large trees, which furnish excellent timber for various purposes, and several valuable gums and dye woods are procured. The buffalo is found wild as well as domesticated, and is used for ploughing and as a beast of burden. Antelopes, goats, pigs, foxes, monkeys, and wild cats are also found. The Spaniards introduced horses and horned cattle, many of which now run wild among the mountains. Sheep and all the domestic fowls were also introduced by them, and have thriven. The crocodile is found in the rivers and lakes; there are several species of tortoise, numerous serpents, some of which are poisonous, and a python said to attain the enormous length of 50 feet. Many kinds of water fowl are found on the lakes, and wild birds in the forests. A species of heron measuring 5 or 6 feet in height, and another from 2 to 3 feet high, are the most remarkable, the latter being often tamed by the natives and taught to dance to the sound of a flute or drum. The most numerous of the feathered tribes are those of the parrot and pigeon families; and there are jungle fowl and a species of pheasant. A bird called the *tubon* leaves its eggs in the sands of the sea shore to be hatched by the sun. The swallows which build the esculent nest so much prized by the Chinese frequent the limestone caves in great numbers. Fish are particularly abundant, and are said to be more so than in any other country; some of them are migratory, entering particular rivers from the sea for the purpose of spawning, at which times great quantities are caught with little trouble by the natives; 18 species found in Europe and the West Indies, and 41 peculiar to these seas, have been enumerated. A kind of sea slug, called *bêche de mer*, or by the Malays *tripang*, a Chinese delicacy, is found on the shores, together with a great variety of shell fish, including the pearl oyster, and the enormous *kima* cockle, some of the shells of which will hold a gallon and are used in the churches as fonts for holy water. Flights of locusts are sometimes experienced, but they are not very destructive. Mosquitoes and ants, including the termites or white ant, are numerous and troublesome on all the islands; but the common fly is not frequent, and fleas and bugs are almost unknown.—The group is inhabited by two distinct races of men, the Malayan and the negrito or oriental negro. The Malays form by far the most numerous part of the population, and are chiefly divided into two tribes, the Tagals and Bisayans. The negritos are found only among the mountains on the 3 principal islands, and are supposed to be the aborigines who have been driven from the more accessible parts by Malay invaders from the adjacent countries. Beside these races, the islands contain a considerable number of Chinese, who have recently settled there, and a comparatively small number of Spaniards and mixed breeds. The houses of the natives are formed of bamboos, raised on posts 8 or 10 feet above the ground, and covered with palm leaves.—The manufactures are not important, and consist chiefly of coarse cloth, straw hats, cordage, and cheroots. For the last named manufacture the islands are particularly famous, but it is a government monopoly, and at Manila employs a large number of hands. (See Manila.) Ship building is carried on to a small extent. The commerce of the Philippines is principally in the hands of foreigners. The value of imports and exports is estimated at $30,000,000 per annum, of which about half belongs to the British. During the year ending June 30, 1858, 51 vessels under the flag of the United States arrived at the Philippines, with cargoes valued at $463,659, and their return cargoes were valued at $2,299,744.—The civil, military, and naval administration of the Philippines and the Ladrone islands is in the hands of a governor general appointed by the crown of Spain, who resides at Manila. The islands are divided into provinces, each under a governor also appointed by the crown. In the parts not subject to the Spaniards, the laws are chiefly formed on the Koran, while among many tribes in the interior pagan customs and superstitions are the only guide. The people who have been fully subjected to Spanish rule have adopted the Roman Catholic religion, while some of the others profess the faith of Mohammed, and the remainder have a belief peculiar to themselves, which does not admit of any future state of reward or punishment. The native languages are barbarous; but the inhabitants of Malay descent are educated.—Many years before the nations of the West found their way into the eastern seas by the routes round the capes, the Arabs had established communication with the Indian archipelago along the W. shore of Hindostan and across the bay of Bengal. Some of their colonies were found in the Philippines when discovered by Magalhaens in 1521. The Spaniards sent a fleet from Mexico in 1565, which took possession of the group and named it in honor of Philip II. of Spain. Zebu was the first island attacked; and a few years afterward a descent was made upon Luzon, and a settlement effected at the mouth of the Manila river. The invaders proceeded to extend their conquests, but in consequence of the great extent of the islands and the warlike spirit displayed by the inhabitants their progress was slow, and even yet they are not masters of the entire group and all the smaller islands in its vicinity. In 1590 the sultan of Sooloo repulsed the Spaniards with heavy loss, and, in defiance of all attempts to conquer them, the inhabitants of that island continued for 3 centuries to maintain piratical fleets in the adjoining seas and to infest the coasts of the Philippines. Manila was attacked by a fleet of Chinese pirates in 1574. In 1639 about 30,000 natives of China had emigrated to Manila, but the Spaniards entertained such a hatred of the race that they slaughtered the greater part of them; and the Chinese, unless converted to Christianity, were not permitted to establish themselves on the islands till very recently. The English besieged Manila in 1762, and the place capitulated, paying $5,000,000 to redeem it from being plundered; but it was restored to the Spaniards when peace was concluded, after an occupation of nearly 2 years. In 1809 the authorities of the Philippines adhered to Ferdinand VII., and opened their ports to the British, since which time other nations have been admitted to the same privileges. The creoles and mixed breeds made an attempt to procure a liberal government in 1820, but the insurrection was suppressed by the Spaniards arming the converted natives. Several earthquakes have occurred since the islands have been known to Europeans, the most recent being in July, 1852.

PHILIPS, an E. co. of Ark., separated from Miss. by the Mississippi river, bounded N. E. by the St. Francis and L'Anguille rivers, and drained by Big creek and other smaller streams; area, 725 sq. m.; pop. in 1860, 14,876, of whom 8,941 were slaves. It has a level surface, swampy in parts, and a fertile soil. The productions in 1854 were 399,010 bushels of Indian corn, 6,473 of oats, and 11,300 bales of cotton. In 1850 there were 5 saw mills, 3 newspaper offices, 4 churches, and 95 pupils attending public schools. Capital, Helena.

PHILIPS, Ambrose, an English poet, born in 1675, died in London, June 18, 1749. He was graduated at Cambridge in 1696, and was one of the authors of the collection of verses published by the university on the death of Queen Mary. Among his earliest poetical compositions are six "Pastorals," which were printed in Tonson's "Poetical Miscellany" in 1709, the pastorals of Pope appearing in the same volume. The rivalry thus provoked led to a violent warfare between the two authors and their respective adherents, and Philips, whose verses are now forgotten, was esteemed by not a few the first of English rustic poets. Pope mercilessly ridiculed Philips's pastorals in a serio-comic paper in the "Guardian." In 1712 Philips produced a tragedy called "The Distressed Mother," founded upon Racine's *Andromaque*. It was played with great success, and received high praise from the "Spectator." In 1722 he brought out two other tragedies, "The Briton," and "Humphrey, Duke of Gloucester;" and soon afterward, in connection with Dr. Boulter, he commenced a serial paper under the title of "The Freethinker," which enjoyed great popularity. When Boulter was made primate of Ireland, Philips became his secretary, and was chosen representative of the county of Armagh in the Irish parliament. In Dec. 1726, he was made secretary to the Irish chancellor, and in Aug. 1733, judge of the prerogative court. Some years after the death of his patron he returned to London (1748), and published a collection of his poems, of which, according to Dr. Johnson, "at least half deserves to be read."

PHILIPS, John, an English poet, born in Bampton, Oxfordshire, Dec. 30, 1676, died Feb. 15, 1708. He was educated at Winchester and at Christchurch, Oxford, where he acquired considerable reputation by his poetical abilities and esteem by his personal virtues. In 1703 he published a burlesque poem entitled "The Splendid Shilling," which was so well liked that in 1705 he was urged to compose a gratulatory poem on the battle of Blenheim. His "Cider," in two books (1706), is an imitation of Virgil's Georgics. His verses are generally well constructed and pleasing, but he closely copied Milton, without possessing the genius which makes imitation pardonable. It has been noticed that in every one of his poems except "Blenheim" he takes occasion to praise tobacco.

PHILISTINES (Heb. *Pelishtein*), a tribe which gave to the Holy Land the name of Palestine, though possessing only the portion on the S. coast bounded by the hilly countries of Ephraim and Judah and extending S. W. to the confines of Egypt. Their origin is unknown, although many modern scholars suppose that they came originally from Crete. They were early settled in Palestine, and from fear of war Moses did not lead the Israelites through their country, which was the most direct route. From the time the Jews passed over into the Holy Land, they were engaged in a perpetual conflict with this warlike tribe, especially during the time of the later judges. Saul, the first Jewish king, fell in a battle against them. David defeated them in several battles, and to some of his successors they paid tribute; but generally they were independent and carried on war against the Hebrew monarchs. Their situation between the contending powers of Assyria and Egypt rendered their land a thoroughfare for the passage of hostile armies. In the time of the Maccabees Philistia was subject to Syria, and subsequently came under the power of the Romans. Its chief cities were Gaza, Ashdod or Azotus, Ascalon, Gath, and Ekron, which early became rich and powerful in consequence of a large transit and maritime trade, which was still further promoted by superior agricultural resources. The religion of the Philistines resembled that of the Phœnicians, the deity most worshipped being Ashtoreth, who was reverenced as Dagon or Decirto at Ascalon, Gaza, and Ashdod. Ekron was the principal seat of Beelzebub, and to the oracle there Ahaziah, king of Samaria, sent when he became sick. They had numerous priests and soothsayers, and in war carried about with them the images of their gods. Of the worship of Dagon a relic still exists in some parts of Syria in the care taken of certain holy fishes.

PHILLIPS, Charles, an Irish barrister, born in Sligo in 1789, died in London, Feb. 1, 1859. He was educated at Trinity college, Dublin, was called to the Irish bar in 1812, and in 1821 to the English bar, at which time he had acquired a considerable reputation as an effective though florid speaker. Some of his occasional addresses on miscellaneous topics were formerly popular, but his oratorical prestige was acquired principally by his professional efforts at the criminal bar. For some years he was regarded as the leading counsel at the Old Bailey. After the alteration of the bankruptcy laws he was appointed by Lord Brougham, then lord chancellor, to the district court of bankruptcy at Liverpool, whence in 1835 he was transferred to the insolvent debtors' court in London as one of the commissioners, a position which he occupied during the remainder of his life. As an author he is best known by his "Recollections of Curran and some of his Contemporaries" (2 vols. 8vo., 1818), of which a 5th edition appeared in 1857, and by a volume of speeches published in 1817, one of which, in the crim. con. case of Guthrie *vs.* Sterne, went through several editions. In the early part of his career he published some pieces of verse, and at various periods of his life pamphlets and historical sketches. His latest efforts in the last named department were "An Historical Sketch of Arthur, Duke of Wellington" (1852), "Napoleon III." (1854), and "Vacation Thoughts upon Capital Punishments" (1856).

PHILLIPS, Georg, a German historian, born in Königsberg in 1804. His parents were English. He was educated at Munich and Berlin, and subsequently went to England, where he passed some months in the study of the Anglo-Saxon laws. Upon his return he renounced Protestantism, and became an ardent defender of the Roman Catholic church, maintaining that it was the basis of all the institutions of Germany, and had of right an absolute supremacy in all things over the civil power. In 1833 he was named professor of civil law at Munich, and afterward royal counsellor at Landshut; but he never performed the duties of the latter office. In 1849 he accepted the professorship of canon law and of legal history at Innsbruck, which he exchanged two years later for that of legal history at the university of Vienna, which position he now holds. He has published works on Anglo-Saxon, English, and German laws, his most important work being *Kirchenrecht* (4 vols., Ratisbon, 1845–'51).

PHILLIPS. I. John, LL.D., an American merchant and scholar, born in Andover, Mass., Dec. 27, 1719, died in Exeter, N. H., April 21, 1795. He was graduated at Harvard college, studied theology, and preached for a time, but subsequently engaged in mercantile affairs. The wealth thus acquired was devoted in large measure to the promotion of education. He endowed a professorship in Dartmouth college, and contributed liberally also to Princeton college. He gave to Phillips academy at Andover $31,000, beside a third interest in his estate; and founded Phillips academy at Exeter in 1781, endowing it at first with $60,000, and subsequently making other donations, and a bequest to it, amounting in all to $84,000 more. II. Samuel, jr., nephew of the preceding, born in North Andover, Mass., in 1751, died in Andover in 1802. He was graduated at Harvard college in 1771, was a member of the provincial congress for 4 years beginning with 1775, a member of the constitutional convention of 1779, a state senator for 20 years following the adoption of the constitution, and for 15 years president of the senate, a judge of the court of common pleas from 1781 to 1798, commissioner of the state in Shays's insurrection, and lieutenant governor at the time of his death. He was also largely engaged in farming, manufacturing, and mercantile pursuits. He planned, founded and organized Phillips academy at Andover, the first incorporated academy in Massachusetts, and one of the earliest in the country. The theological seminary at Andover, which grew out of this academy, was a development of his plan. He gave the academy some lands, and procured endowments for it from his father, uncles, and cousin, to the amount of $63,000. At his death he left to the town of Andover a fund of $5,000, the income to be used for the purpose of aiding the professional acquirements of female teachers in the town, of extending the annual terms of instruction of its common schools, and for the purchase and gratuitous distribution of certain specified books to "poor and pious Christians."

PHILLIPS, John, an English geologist, born Dec. 25, 1800. He is the nephew of William Smith, the "father of English geology," and in 1815 became the pupil and assistant of his uncle, and accompanied him in the surveys made for the preparation of a series of geological sections and county maps. About 1827 he was appointed keeper of the museum of the Yorkshire philosophical society, and delivered courses of lectures in various parts of England on geology, general physics, chemistry, mineralogy, and natural history. After having successively occupied the chair of geology in King's college, London, and in the university of Dublin (1844), he was appointed in 1856, on the death of Dr. Buckland, professor of geology in the university of Oxford. As assistant general secretary of the British association since 1832, he has arranged and edited the numerous volumes of reports, including the proceedings, recommendations, and transactions of the association. In 1858 and 1859 he was elected president of the geological society. He has written various works on geology.

PHILLIPS. I. Richard, an English chemist, born in 1778, died in London in 1851. He was a pupil of Dr. George Fordyce, and one of the founders of the Askesian society for the discussion of philosophical subjects, established in 1796. He was successively lecturer on chemistry in various public schools, and in 1839 was appointed curator and chemist of the museum of economic geology, now the museum of practical geology, which office he held till his death. In 1821 he became the conductor of the "Annals of Philosophy," and upon the incorporation of that journal with the "Philosophical Magazine" he was retained as one of the editors. In 1822 he was elected a fellow of the royal society, and during 1849 and 1850 was president of the chemical society of London. He discovered the presence of phosphoric acid in uranite, a fact which had escaped the attention of Berzelius. II. William, an English geologist, elder brother of the preceding, born in London, May 10, 1775, died at Tottenham Green in 1828. He was one of the founders of the Askesian society, and in 1801 contributed to its proceedings a communication on the divining rod. He was an early member of the geological society, and in 1827 was elected fellow of the royal society. Mineralogy and crystallography are especially indebted to him for a large number of exact measurements of crystals by the reflecting goniometer of Wollaston. Beside contributing a number of papers to the "Transactions of the Geological Society," he wrote communications for scientific periodicals, and published works on mineralogy and geology, which had great influence in popularizing those branches of science.

PHILLIPS, Wendell, an American abolitionist, born in Boston, Mass., Nov. 29, 1811. He is a son of John Phillips, first mayor of Boston, was graduated at Harvard college in 1831, and at the Cambridge law school in 1833, and was admitted to the Suffolk bar in the following year. It was at this time that the excitement resulting from the agitation of the slavery question had spread throughout the country, rising to an unparalleled degree of intensity, and culminating in 1835 in numerous outbreaks of mob violence. A witness of the Boston mob of 1835 (see GARRISON, WILLIAM LLOYD), Mr. Phillips joined the abolitionists in 1836, relinquishing his professional practice in 1839, from unwillingness to act under his attorney's oath to the constitution of the United States. He made his first speech worthy of mention in Dec. 1837, on the occasion of a meeting of citizens in Faneuil hall, "to notice in a suitable manner the recent murder, in the city of Alton, of the Rev. Elijah P. Lovejoy, a native of New England, and citizen of the free state of Illinois, who fell in defence of the freedom of the press." At a moment when the purpose of the meeting seemed likely to be defeated, and its resolutions rejected, by the opposition of Attorney-General Austin, Mr. Phillips, who was among the audience, in an outburst of indignant eloquence, at once rebuked the attorney-general for the sentiments he had uttered, and secured the passage of the resolutions. Since that time he has been a prominent advocate of the doctrines of the Garrisonian school of abolitionists, who, believing the constitution of the United States to be an immoral compact between freedom and slavery, and the Union resulting therefrom the main prop of the slave system in America, refuse to swear to support the former, and consequently abstain from voting, and labor for the dissolution of the latter, as the best, if not the only, means of effecting emancipation. Mr. Phillips is also identified with the progress of the temperance and woman's rights movements, and with efforts for the amelioration of the criminal law. He is a frequent public lecturer on miscellaneous subjects. As an orator, Mr. Phillips is ranked among the very foremost that America has produced. His lectures and speeches have never been collected, but may be found in the pages of the Boston "Liberator" and the New York "Anti-Slavery Standard."

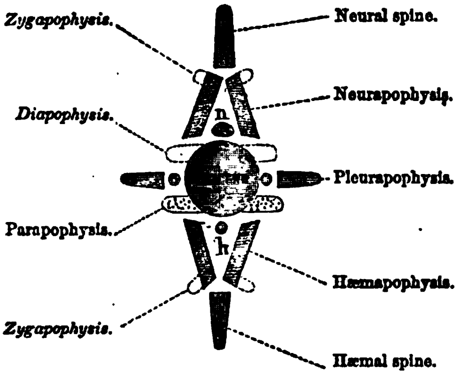
PHILO JUDÆUS, a Jewish philosopher of Alexandria. The place and time of his birth are uncertain, but from indications in some of his writings it may be inferred that he was born in Egypt a few years before Christ. He was of the priestly tribe, and was honored with important political trusts, among others with the charge of the embassy sent to Caligula, after the massacre of the Jews in Egypt, to defend that people against the calumnies of Apion. It is stated by Eusebius that, on a second embassy to the emperor Claudius, Philo became acquainted with the apostle Peter at Rome. With the exception of a visit to Jerusalem to which he alludes, nothing more is known of his history, except that he lived and taught at Alexandria, enjoying great personal popularity, and exercising by his writings a wide influence upon the opinions of his Jewish brethren. By the marriage of his son to a daughter of King Agrippa he was allied to the royal house of Judæa. He appears to have lived to old age, although no account is given of his death. Philo belonged probably to the sect of the Pharisees, but departed widely from the methods of that sect in his system of interpretation. While he held firmly to the law of Moses and to all the Jewish traditions, he was a Platonist in his ideas, and endeavored to reconcile the philosophy of the Grecian sage with the records of the Hebrew lawgiver. The method which he adopted of allegorizing the sacred history had already been tried in the schools of Alexandria, but was carried so far by Philo that it became in some sense a new science. His general purpose was to show that the Mosaic revelation contained in germ all that was afterward developed into the various forms of Greek philosophy. He finds the principal doctrines of the stoics and the Eleatics, not less than of the Platonists, in the Scriptures of the chosen people of God; and in his characteristic doctrine of the Logos and of the ideal and archetypal world, he anticipates the speculations of the Gnostics. The writings of Philo, which are numerous, are mostly on subjects connected with the narrative of the book of Genesis or the Levitical law, or suggested by some incident in that record. Some of his treatises are polemic and apologetic. They are of great importance, not only as showing the state of opinion among the Jews in that age, but also as illustrating the Christian and apostolic history in their allusions. The best edition of the works of Philo is that of Thomas Mangey (2 vols., London, 1742), but additional treatises were discovered by Cardinal Mai (1818), and others exist in Armenian versions (Venice, 1822). The only English translation of them is that by Mr. C. D. Yonge, in Bohn's "Ecclesiastical Library" (4 vols. 12mo.).

PHILOLOGY. See LANGUAGE.

PHILOPŒMEN, the last great general of the Greeks, born about 252, died by poison in Messene in 183 B. C. His father, Craugis, was one of the most prominent men of Megalopolis, and belonged to a noble family of Arcadia; but dying early he left his son to be brought up by his friend Cleander. The studies of Philopœmen were chiefly literature, philosophy, and war, the last of which he considered, according to Plutarch, "the most important and useful occupation of men, and despised those who were not versed in it." As soon as he became old enough to enter the military service, he eagerly participated in the incursions which were at that time often made into Laconia. He first appears prominently in 222, when Cleomenes III. of Sparta having seized upon Megalopolis by night, Philopœmen with a few others made a most determined resistance. The following year Antigonus Doson, king of Macedon, coming into the Peloponnesus to the assistance of the Achæan league, Philopœmen joined his army with 1,000 foot and a detachment of cavalry, and contributed mainly to the victory of Sellasia, where he refused to leave the field, though wounded in both thighs by a javelin. In this battle his generalship and courage had been so conspicuous, that Antigonus offered him a command in his army; but Philopœmen, who hoped to secure the unity and independence of Greece by means of the Achæan league, declined. As peace prevailed at home, however, he went to Crete and assisted the city of Lyttus in its war against Cnossus. Aratus, the founder of the Achæan league, having died in 213, Philopœmen on his return in 210 was made commander of the cavalry. Aratus had gained his successes by means of Macedonian mercenaries; but Philopœmen infused a love of military glory into the Achæan youth, and trained them to the use of arms. In 209 he accompanied Philip, the successor of Antigonus Doson, in the expedition against Elis, and in a battle near the river Larissus defeated the Ætolians and Eleans, and slew their leader, Damophantus, with his own hand. A war broke out between the Achæans and Machanidas, tyrant of Sparta, and in a battle fought at Mantinea Philopœmen totally routed the enemy, himself killing the Spartan king. He was hailed as liberator of Greece, and so seriously did his plans conflict with those of Philip of Macedon, that an unsuccessful effort was made by that prince to have him assassinated. In 202 Nabis, who had succeeded Machanidas in the government of Sparta, seized upon Messene, and Philopœmen, being unable to persuade Lysippus, then general of the league, to take the field, collected a body of armed men himself and drove the tyrant back into Laconia, and the following year, having been elected strategus, defeated his army at Scotitas with much slaughter. Being succeeded in the office by a partisan of Philip, he went to Crete a second time and took command of the forces of the city of Gortyna. Returning in 194, he found that Nabis had renewed his hostilities against Megalopolis, but that both he and Philip had been defeated by the Romans under Flamininus, who had formed an alliance with the Achæans. No sooner, however, had Flamininus left Greece than Nabis began the war again, invaded Achaia, and besieged Gythium. To relieve this town Philopœmen fitted out a fleet, which however failed to accomplish its purpose; but marching against Sparta, although he fell into an ambush, he defeated the enemy with terrible slaughter. Shortly after his return Nabis was murdered by his Ætolian auxiliaries, whereupon Philopœmen hastened to Sparta and induced that city to join the Achæan league. In 189, however, the party hostile to him gained the supreme power there, and the connection with the league was dissolved, 30 of Philopœmen's friends being put to death. Both sides appealed to Rome. An ambiguous answer was returned by the senate, which the Achæans interpreted in their own favor, and in 188 Philopœmen, as strategus, marched into Laconia. Sparta submitted, and was treated with great rigor. The walls of the city were razed, the exiles were all restored, all inhabitants brought in or enfranchised by Nabis were required to depart on a fixed day, the laws and institutions of Lycurgus, which had subsisted, either well or ill observed, for 7 centuries, were abolished, and the citizens were obliged to adopt those of Achaia. Of the disfranchised, 3,000 refusing to leave the country were sold as slaves. These severe measures offered an opportunity to the Romans of again interfering, who compelled the granting of a general amnesty and the restoration of the political exiles. In 183 Philopœmen was elected strategus for the 8th and last time. Messene now dissolved its connection with the league, whereupon the Roman ambassador, Flamininus, wrote to Philopœmen, desiring him to call together a meeting of the Achæans to discuss the affairs of that city. This he declined to do, and collecting a detachment of cavalry hastened forward to reduce Messene, but being repulsed was thrown from his horse and fell into the hands of the enemy. At night an executioner was sent to him with a cup of poison, and hearing that the troop he had led had retired in safety, he said: "Then we are not altogether unhappy," and drained the cup. The news of his death excited great indignation in Achaia, and Lycortas at the head of an army immediately entered Messenia and ravaged the country far and wide. Dinocrates the Messenian leader slew himself, and his accomplices in poisoning Philopœmen were stoned to death. The body of Philopœmen was burned, and the ashes put in an urn were carried to Megalopolis by the historian Polybius, in a solemn procession of the army, and statues to his memory were erected in almost all the cities of the league.

PHILOSOPHICAL ANATOMY, a department of anatomical science, based on data furnished by descriptive and comparative anatomy, embryology, and histology, to which are applied the philosophical principles employed in mental and moral science. It is also well called transcendental anatomy, as it seeks a fundamental unity in all the forms of nature, and, in the usual restricted signification of the term, aims to establish a primary plan or archetype of which all skeletons, at least of the vertebrata, are modifications. A brief sketch of the various systems from Oken to Owen cannot fail to render more intelligible the true character of the human skeleton, external and internal, by presenting the primitive type of which they are the extremely modified forms. Referring the reader to the concluding part of the article on Comparative Anatomy for the main features of its origin and progress, it will be sufficient here to say on these points that it was studied carefully by Oken and Carus in Germany, by Geoffroy St. Hilaire in France, and by Owen in England. Presuming that the reader has a knowledge of anatomical terms, without which all these systems will be unintelligible, we may at once introduce that of Lorenz Oken, who indisputably stands at the head of philosophical anatomists. As early as 1807 he made 3 cranial vertebræ, which he calls those of the ear, jaw, and eye, proceeding from behind forward; the auditory nerves traverse the 1st, the trifacial the 2d, and the optic the anterior or 3d; the petrous bone he considers a sense capsule of the ear; he recognizes the vomer as a 4th rudimentary vertebral body, with the lachrymal bones as laminæ or *neurapophyses*, and the nasals as spinous processes or neural spines; the palate bones he regards as the ribs of the head anchylosed; the squamous portion of the temporal bone of mammals and the tympanic of birds represent the scapula and ilium of the head; he recognized the arm, forearm, and hand in different parts of the upper jaw, and the corresponding bones of the posterior limbs in the lower jaw; the clavicles of the head were the pterygoid bones. In fact, the head was to him a repetition of the whole trunk with all its systems; he even goes so far as to state as a fundamental principle that the whole osseous system is only a repetition of a vertebra. This system was at first scoffed at, but the striking character of some of his homologies opened the eyes of his countrymen to the new light; after various modifications suggested by other observers or the results of his own researches, in 1843, in his "Physiophilosophy" (Ray society translation, London, 1847), he pursues his cranial homologies still further, always regarding the head as a repetition of the trunk, a doctrine strenuously combated by Owen. The present article will not permit any extended exposition of his theory, which is detailed at length in the work just quoted, pp. 318–422. His cranial vertebræ are: 1. The occipital, consisting of the body, 2 condyles, and crest of this bone; this is also the auditory vertebra, as it encloses the auditory bones, and cerebellum which gives off the nerves of hearing. 2. The parietal, consisting of the body of the posterior sphenoid, the greater wings, and the parietal bones; this is also the lingual vertebra, the maxillary and lingual nerves passing through the wings. 3. The frontal, composed of the body of the anterior sphenoid, orbital or lesser wings, and 2 frontals; this is also the optic vertebra, the optic nerves passing through the orbital plates; it also surrounds the cerebrum. 4. The nasal, consisting of vomer, ethmoid, and 2 nasal bones, containing the olfactory nerves. The skull contains, therefore, a vertebra to each sense; the sense of touch is disseminated over the whole body, and its vertebræ are 35, 15 in the neck and chest, 5 in the abdomen, and 15 in the lumbar, sacral, and caudal regions. This system is normal only in the human type, animals being irregular men. He says the pectoral and abdominal muscles are ennobled in the muscles of the face; the mouth is the stomach in the head, the nose the lung, the tongue the end of the intestine converted into muscle, and the salivary glands the liver.—The poet Goethe first suggested to anatomists the idea of representing the mutual relations of the bones by figurative diagrams; he had conceived the idea of the cranial vertebræ as early as 1790, but did not make it public until after Oken's inaugural dissertation in 1807. In his essays on comparative anatomy (1819–'20) he made 6 vertebræ in the mammalian head, 3 on the posterior part enclosing the "cerebral treasure" and its delicate subdivisions, and 3 anterior communicating with the external world; these vertebræ are the occipital, posterior and anterior sphenoid, palatal, upper jaw, and intermaxillary. Duméril (*Magasin encyclopédique*, 1808) showed the analogy of the cranial segments and their muscles to the spinal vertebræ and muscles; he regarded the basi-occipital bone as a vertebral body, the condyles as oblique processes, the occipital protuberance as a spinous process, and the mastoid as a transverse process. He considered the body of the sphenoid as perhaps a 2d vertebral centre, but rather inclined to the opinion that the head consisted of a single huge vertebra, with similar form, use, and muscular attachments as a spinal vertebra. Spix (*Cephalogenesis*, 1815) adopted the number and composition of the cranial vertebræ of Oken's system, only giving them new names. De Blainville (1816) taught in his lectures that the head consists of a series of consolidated vertebræ, developed in proportion to the nervous system contained within them, with simple appendages (ribs), or compound (jaws, limbs, &c.); this is further developed in his *Ostéographie* (1839) and *Histoire des sciences de l'organisation* (1845). Bojanus (*Isis*, 1818) made 4 cranial vertebræ, the 4th being the nasal, whose neural arch he determined, and the ribs of the tympanic; he named the vertebræ acoustic, gustatory, optic, and olfactory.—Geoffroy St. Hilaire (*Annales du muséum d'histoire naturelle*, 1807, vols. ix. and x.) recognized the homology of the pectoral fins of fishes with the anterior extremities of birds, of the bony apparatus of a sternum and its annexes with these parts in higher vertebrates; he attempted the determination of the cranial bones in the crocodile, dividing them into those of the mouth, nose, eye, ear, and brain, regarding the skull as a kind of house with chambers for the lodgment and protection of the brain and organs of sense, but he did not at that time appear to have had the idea of cranial vertebræ; he showed that the cranium of birds was composed of the same bony pieces as that of man and mammals, recognizing a unity of plan of organic composition in all the vertebrata. His *Philosophie anatomique* (2 vols. 8vo., Paris, 1818–'22) developed his ideas on the homologies of the vertebrate skeleton; in the *Mémoires du muséum d'histoire naturelle* (vol. ix., 1822, pp. 76–119) he has given his ideas on the structure and typical form of the vertebra, and a representaview in fig. 5. In the *Annales des sciences naturelles* (vol. iii., 1824) he explains in a synoptic table (plate 9) the composition of the bony head of man and vertebrates; he makes 7 vertebræ as follows, from before backward: the labial, nasal, ocular, cerebral, quadrigeminal, auricular, and cerebellar. He studied the homologies of the hyoid arches more carefully than his predecessors; he made 9 pieces in each vertebra, combining, however, some of the parts of the external or dermal skeleton to which the vertebral theory does not apply; he regarded the branchial arches of fishes as the homologues of the tracheal rings of terrestrial vertebrates. With all his errors, Geoffroy St. Hilaire gave a great impetus to the study of philosophical anatomy in France. His most powerful and constant antagonist was Cuvier, who treated with ridicule and contempt this form of German philosophy; these two anatomists carried on their discussions, both by lectures and writings, with all the eagerness and often the bitterness of a partisan spirit; ability and brilliancy were on the side of Cuvier, but truth and the more philosophical treatment of the subject were with Geoffroy St. Hilaire. Thus opposed to each other, the science of philosophical anatomy, instead of making progress in France, at the death of these two colleagues had fallen into a very chaotic and unsatisfactory condition.—Carus of Dresden (1828) was the most successful cultivator of philosophical anatomy after Oken; in his *Grundzüge der vergleichenden Anatomie und Physiologie* (translated into French by Jourdan, Brussels, 1835) he gives fair credit, though slight mention, to French anatomists, and lays great stress upon the researches of Germans in this direction; he says incidentally that philosophic osteology owes nothing to the English and Italians, an assertion since contradicted by the appearance of the works of Richard Owen, who, if any one, may be said to represent the present opinion of the scientific world in matters of philosophical anatomy. Carus maintains that the same relation exists between the 3 cranial vertebræ and the 3 cerebral masses pertaining to the 3 great sensorial nerves (of hearing, vision, and smell), as between each spinal vertebra and the ganglionic swelling of the cord which it envelopes. He gave the name of dermatoskeleton to that which in solidifying separates an animal from the external elementary substance, air or water; this external elementary substance also penetrates within the animal, requiring a more or less solid limitation internally, in the alimentary and respiratory systems, constituting the splanchnoskeleton; the neuroskeleton is that which limits and protects the nervous system, being peculiar to the vertebrates, the most perfectly developed and in proportion to the nervous system. The dermatoskeleton is the first and lowest in the animal kingdom; it appears as horny envelope, shell, scales, osseous plates, and skin; it is increased from without, permanent or deciduous, and reproduced by the coagulation or calcification of the integument. The splanchnoskeleton is also inferior in rank, cartilaginous, but capable of undergoing bony transformation in the higher animals; tracheal rings, branchial arches, and teeth belong to this skeleton; the neuroskeleton is formed as indicated in the article BONE. He divides the cerebral mass into 3 portions, cerebellum, cerebrum, and optic lobes between them, with 3 pairs of ganglia in front; the spinal ganglia, in man, are 30. He constructs the skeleton on geometrical principles, starting from the hollow sphere, double cone, and cylinder; he makes what he calls proto-, deuto-, and trito-vertebræ; the 1st (ribs) enveloping the body and its viscera, in relation with vegetative life; the 2d (vertebræ) protecting the nervous system; and the 3d (limbs) becoming the osseous framework which sustains the muscular and locomotive organs. His 3 principal cranial vertebræ correspond to the 3 cerebral masses, and are the occipital, centricipital, and sincipital; the 3 facial vertebræ form the nose and its cartilages, and the 3 intervertebræ, he names auditive, optic, and olfactory. It has been found, however, that it is impossible to explain the vertebrate homologies by his diagram archetype; for this the reader is referred to the work above cited. In fishes we find the first development of the neuroskeleton, as distinguished from the splanchnic and external skeletons, but at its lowest stage, being cartilaginous or partially osseous; it is of inferior vitality, and the component parts are imperfect in form and number; in this class the sexual organs predominate. In reptiles the neuroskeleton is for the first time bony; the splanchnic skeleton is truly cartilaginous, and the external truly corneous; the abdominal region or the digestive system predominates. In birds the thoracic region or respiratory system predominates, extending even into the cavities of the bones and feathers. In mammals the cranium predominates and the nervous system; the neuroskeleton being the highest developed, with a corresponding inferiority of the external and splanchnic skeletons. Carus divided the vertebra into 6 portions, and the skeleton generally into this number or its multiples, while Oken adopted the number 5.—Meckel did not materially affect the progress of philosophical anatomy, but he confirmed many previous principles and homologies by his minute and accurate descriptions, his knowledge of individual formations, and his history of development.—Prof. Owen has given the greatest extension to the science of philosophical anatomy in various writings and lectures since 1838, among which may be mentioned his various "Hunterian Lectures," "Lectures on Comparative Anatomy" (invertebrates and fishes), "On the Archetype of the Skeleton," "On the Nature of Limbs," and "On the Principal Forms of the Skeleton and Teeth;" the last is the most popular, and has been reprinted from "Orr's Circle of Sciences" at

Philadelphia (12mo., 1854). As far as the skeleton is concerned, the aim of philosophical anatomy is to discover the original idea which presided at its construction, or the archetype to which all the modifications of the vertebrate series can be referred. The archetype refers principally to the neuroskeleton, which alone appears to have any typical pattern; beside the other skeletons already defined by Carus, and of which good examples (of the dermatoskeleton) may be found in the plates of the sturgeon, crocodile, and armadillo, and the carapace of the tortoise, he mentions a scleroskeleton, or bones developed in tendons, ligaments, and aponeuroses. In order to understand his terms, and to comprehend his archetype skeleton, it will be useful to study his typical vertebra, here given:



In the above figure the names printed in Roman letters are the autogenous elements, or those which are ordinarily developed from distinct and independent centres; the names in Italics indicate the processes which are continuations of some of the preceding elements; the latter are the *diapophyses* or superior transverse processes, and the *zygapophyses* or oblique articular processes of human anatomy. The autogenous elements enclose generally foramina which form canals in the vertebral chain; the most constant and extensive canal is that marked *n*, above the central body, for the lodgement of the spinal cord or neural axis, composed of the laminæ hence called *neurapophyses;* the second canal, marked *h*, below the centrum, is more irregular and interrupted, lodging the central vessel and the great trunks of the vascular system, and is formed by the lamellæ hence called *hæmapophyses.* On the sides of the centrum, most commonly in the region of the neck, is a canal circumscribed by the *pleurapophyses* or costal processes, the *parapophyses* or inferior transverse processes, and the *diapophyses* or superior transverse processes. Thus a perfect or typical vertebra, such as is found in the thorax of man and most of the higher vertebrates, and in the neck of many birds, with all its elements, presents 4 canals around a common centre; in the tail of most reptiles and mammals the hæmapophyses are joined to the lower part of the centrum, protecting only the artery and vein; but when the central organ of circulation is placed within it, the hæmal arch is largely developed, as in the thorax, where the pleurapophyses (ribs) are much elongated, and the hæmapophyses (costal cartilages) are removed from the centrum and placed on the end of the ribs, the bony circle being completed by the hæmal spine or sternum; the neural spine is the equivalent of the superior spinous process. He shows the fallacy of Cuvier's definition of a vertebra; the latter maintained that vertebræ have a special number of pieces arranged in a definite manner, looking more at their position in the series than at their composition; his prejudices against the vertebral theory led him into many untenable and contradictory statements and definitions. Cuvier divided the bones of the head into cranial and facial, making 8 annular segments of the former; the anterior comprised the frontal and ethmoid, the middle the parietals and sphenoid, and the posterior the occipital, the temporals being intercalated between the occipital, parietal, and sphenoid; he does not apply this to the lower vertebrates, in which it is most evident, nor to the face, or he would have found that these divisions do not include the same bones in all animals, the same being in one a cranial and in another a facial element; this again involved him in many inaccuracies and contradictions. Owen divides the endoskeleton of the human head into 4 segments, as follows, beginning behind: 1. Occipital or epencephalic vertebra, with the following composition: centrum (c.), the basi-occipital portion of the occipital bone; parapophyses (p.) and neurapophyses (n.), coalesced into the lateral or condyloid portions, the former marked by the ridge for the *rectus lateralis* muscle; neural spine (n. s.), the proper occipital bone; pleurapophyses (pl.), the scapulæ; diverging appendages (d. a.), the bones of the upper extremity; hæmapophyses (h.), the coracoid processes of the scapulæ; and hæmal spine (h. s.) deficient. The clavicle and first segment of the sternum, which complete the mammalian scapular arch, are the hæmapophyses and hæmal spine of the atlas or first cervical vertebra. 2. The parietal or mesencephalic, with c., the basisphenoid or posterior part of the body; p., mastoid processes; n., greater wings of sphenoid; n. s., parietal bones; pl., styloid processes; d. a., greater cornua of hyoid bone; h., lesser cornua; and h. s., body of hyoid. 8. Frontal or prosencephalic, with c., anterior body of sphenoid; p., external angular processes of frontal (post-frontals of fishes); n., lesser wings of sphenoid; n. s., frontal bone; pl., tympanic portion of temporal; d. a. deficient; h., articular portion of lower jaw; and h. s., dental portion of same. 4. Nasal or rhinencephalic, with c., vomer; n., *ossa plana* of ethmoid; n. s., nasal bones; pl., palate bones; d. a., pterygoid and malar bones, with *squamous* and zygomatic portions of temporal; h., superior maxillary bones; and h. s., intermaxillaries. The splanchnoskeleton of the head consists of the petrosal and ear bones, the turbinated bones, and the teeth; the external skeleton consists of the lachrymal bones. These 4 cranial vertebræ, according to the organs of sense, would be: 1, auditory, related to the organ of hearing; 2, gustatory, with the organ of taste, whose nerve (gustatory or trifacial) pierces the neural arches of this segment or passes between it and the frontal; 3, optic, with the organ of vision between this and the nasal segment; and 4, olfactory, with the organ of smell always in front. Agassiz, in the first volume of his *Poissons fossiles*, arguing from the fact that the cephalic extension of the *chorda dorsalis* is arrested in the embryo fish at the region of the greater sphenoidal wings, maintained the "existence of only one cranial vertebra, the occipital, the rest of the head remaining foreign to the vertebral system;" this is refuted by Owen, and probably its author does not now adhere to it. Owen also combats the idea of Oken that the head is a repetition of the whole trunk; he maintains that the jaws are not the limbs of the head, but are the modified hæmal arches of the 2 anterior segments; the anterior limbs are diverging appendages of the occipital segment, and the posterior of the pelvic segment with its hæmal arch, both variously displaced from their hæmal arches in different vertebrates. The diverging appendages of the ribs of fishes, reptiles, and birds, arising from their posterior edge, are essentially limbs, rudimentary arms and legs, though they never become such; in this view angels' and Cupid's wings, and the arms of the mythological Briareus, are philosophical possibilities from the development of one or more of these divergent appendages, though zoological nondescripts. As the cranial segments are in number according to the special nerves of sense, so the development of the vertebral bodies and neural arches in the trunk depends on the junction of the nerves with the spinal cord; the condyloid foramen of the occipital bone gives passage in man to the hypoglossal nerve. The cranial bones of fishes are exceedingly complicated, and have taxed the ingenuity of most comparative anatomists, and tried to the utmost the patience of their readers; those who wish to try the experiment are referred to Owen's "Comparative Anatomy of Fishes" and "Homologies of the Vertebrate Skeleton," where the author labors very hard, and not always very satisfactorily, to reduce every thing to his archetype. It will be interesting and instructive to give a few of the most striking characters of the skeletons of the different classes of vertebrates, according to Owen. In the fish not only the jaws, but the arms and legs, may belong to the skull, which accordingly is developed out of proportion to the rest of the body; the diverging appendages of the frontal vertebra are the chain of opercular bones, and of the parietal the branchiostegal rays; of the first spinal vertebra the pleurapophysis is short and simple, and the hæmapophysis is the clavicle; in the abdominal segments the pleurapophyses support simple rays as diverging appendages, and the hæmal arches are fibrous; the hæmapophysis of the pelvic segment is ossified into an ischium sustaining the ventral fins or posterior limbs, in some instances united to a rib; this pelvic arch is most remarkably changed in position, being as above mentioned in the so called abdominal fishes (like the salmon, herring, and pike), or joined to the scapular arch as in the thoracic fishes (like the cod and perch families), according as the ischium is joined to the coracoid by a longer or shorter development. The bony and fibrous parts of the hæmal arches contract rapidly beyond the abdomen; the parapophyses increase gradually, curve downward, and complete the arch as in the cod, or the pleurapophyses contribute to form it with them as in *lepidosteus*, or the arch is closed by the former, with the latter anchylosed below and diverging at the points, as in the tunny. The bodies of some of the terminal segments in typical osseous fishes are consolidated together, and support several neural and hæmal arches and spines, which form the more or less expanded base of the caudal fin. The dorsal, anal, and caudal fins are folds of the skin supported on spines between the neural and hæmal spines to which the fin rays are articulated; they form no part of the typical vertebrate skeleton, and are peculiar to fishes. As compared to his archetype figure, the fish skeleton departs from it in the excess of development, principally in the diverging appendages of the cranium, and in the arrest of development in most of the other segments; the principle of repetition predominates, and the segments resemble each other more than in the higher classes. In the reptile skeleton, the hæmal arches of the anterior 2 cranial vertebræ, the jaws, are more developed, while that of the parietal is feebly so, and they are more or less displaced backward; in the occipital segment the hæmal or scapular arch is still further displaced backward and entirely separated, to it is attached an additional single bone, the humerus, and the divisions of the terminal segments are reduced to 5, a number not surpassed in any of the higher vertebrates. A part of the body of the atlas is developed separately, and is united to the 2d cervical vertebra, forming the odontoid process; the 9 segments after the cranium are cervical vertebræ, movably articulated, the hæmal arches not being ossified, and the pleurapophyses feebly developed, but free or floating; the 9 to 12 following are dorsal vertebræ, the elongated ribs with the hæmal arch completing the circle, the pieces of which are movable; the next 2 are the lumbar, without free and bony ribs, but with hæmal arches; the next 2, united, form the sacrum, bearing the pelvic arch, consisting of pleurapophyses (ilium), hæmapophyses (ischium and pubis), with the divergent appendages of the posterior limbs, a higher development than in fishes; beyond the sacrum all the vertebræ are caudal, in which the pleurapophyses become gradually shorter, a few of the first attached to diapophyses, and the hæmapophyses articulated between and to 2 vertebral bodies. In this class we see for the first time regions of the body. In the bird skeleton the premaxillary is much more developed than the maxillary, the reverse of what is seen in reptiles; the greater volume of the brain requires an increased cranial cavity, which is obtained by the expansion of the neural arches and spines without the addition of any new bones; the cervical segments have short and free pleurapophyses or ribs, which are early united to the neural arches, forming numerous simple vertebræ, and giving length and flexibility to the neck; the detached hæmapophyses of the atlas are usually joined together at their extremities, forming a thin osseous arch, the furcular bone; in the thorax the latter are ossified into sternal ribs, the pleurapophyses being the vertebral ribs, bearing diverging appendages, pointing backward, which serve to unite the ribs and to render the thorax more solid; the hæmal spines of the anterior thoracic segments are developed into the broad sternum characteristic of birds, with its keel on the median line large in proportion to the powers of flight. The sacral region is greatly developed, both in the extent and in the number of bones firmly united to form it, and in its enormous pleurapophyses, especially the ilium; the sacrum includes some of the last dorsal, the lumbar, the sacral, and even some of the caudal vertebræ as limited in the reptile skeleton; after the sacrum come 5 or 6 caudal, more or less united, the last compressed laterally and directed upward. The pelvis has only 2 hæmapophyses, the pubis and the ischium, not united on the median line, except in the ostrich for the former and the nandou (*rhea*) for the latter, the rule being that the pelvis of birds is open below. The diverging appendages of the scapular and pelvic arches, or the anterior and posterior limbs, agree in having only 2 bones in the carpus and tarsus, and 3 united in the metacarpus and metatarsus, supporting in the former the 2d, 3d, and 4th phalanges, that of the 2d very rudimentary; in the metatarsus the 3 bones are, except in the penguins, united for their whole length, including also the 2 tarsal bones; the rudimentary metatarsal of the great toe is not anchylosed, and is directed backward, supporting the hind toe with 2 phalanges; the 2d toe has 3 phalanges, the 3d 4, the 4th 5, the 5th or little toe being wanting; by the number of phalanges we know that, in the African ostrich, the external or shortest toe of the 2 by its 5 joints is the 4th, and the internal the 3d, longer than the other, though having only 4 joints. In the mammal skeleton the cranial cavity is expanded, as in birds, chiefly at the expense of the neural spines, frontal, parietal, and occipital; but in most the squamous portion of the temporal bone forms part of the cranial walls; the occipital is articulated to the atlas by zygapophyses or condyles developed from the neural arches, and the hæmal or scapular arch is generally far removed from the skull; the hæmapophyses of the atlas, or clavicles, vary much in extent, degree of ossification, and even in their presence; the pleurapophyses of the cervical vertebræ are very short, and are generally united to the other elements, circumscribing the foramen for the vertebral artery. The number of the cervicals is 7, except the alleged 6 in the manatee and the 8 or 9 in the 3-toed sloth; this number depends on the existence of the diaphragm, &c., determining the number and distribution of the pairs of cervical nerves; in some whales and armadillos they are more or less consolidated. In the dorsals the pleurapophyses or ribs are movable, and the anterior ones are articulated between 2 vertebræ; the hæmapophyses are the costal cartilages, and the hæmal spines are generally a distinct chain of bones, in the highest consolidated into a sternum; toward the loins the pleurapophyses become shorter, and are attached to their respective vertebral centres and to the diapophyses; the hæmapophyses become shorter, and finally free and floating. The caudals vary much in number, size, and form; the short pleurapophyses in the anterior ones are developed at the end of diapophyses, and the hæmal arch, when it exists, is articulated directly to the bodies. The limbs (except in cetaceans, where the posterior are wanting) are much alike, whether adapted for flying, digging, swimming, running, or climbing, as will be seen under the homotypes below. In the fish and reptile the vertebral column is straight or nearly so; in the bird the skull forms a right angle with the neck, the latter having a sigmoid curve, and the tail bent upward; in the springing mammals, like the carnivora, there is a convergence of the spinous processes toward the 11th dorsal, and in most there is a similar convergence toward the 4th cervical, these two regions being the centres of special movements of the column; in bulky animals, like the elephant, which move with a rigid spine, these processes are all inclined a little backward, as in crocodilians. In man the spine has several slight and graceful curves, destined to prevent shocks to the nervous system from movements incidental to the erect position; the curvature of the sacrum and coccyx are greatest compared with the number of vertebræ, and the anterior and posterior diverging appendages reach the maximum of development, especially the latter as compared to the length of the spine; the thumb, the least constant in the rest of the class, becomes in him the most important, constituting a hand proper; in like manner the great toe, the first obliterated in other mammals, is characteristic of the genus *homo*, as on it depend principally the erect posture and biped gait of man; even the highest monkey has a posterior thumb instead of a great toe. In the class of serial homologies, or homotypes, may be mentioned the homology of the scapula with the ilium, the humerus with the femur, the ulna with the fibula, radius with tibia, carpus with tarsus, metacarpus with metatarsus, fingers with toes; in the skull, the basi-occipital, basi-sphenoid, pre-sphenoid, and vomer are the homotypes of the vertebral bodies; the coracoid, superior maxillary, clavicle, pubis, ischium, chevron bones, sternal or abdominal ribs and cartilages, and tendinous intersections of the *rectus abdominis*, are all homotypes and hæmapophyses. This system of homotypes is far more natural, satisfactory, and intelligible than that of Oken, Spix, and Carus, who speak of the scapula, ilium, femur, humerus, &c., of the head, regarding each part as a repetition of the whole; an idea which Cuvier ridiculed in the most scornful manner.—This is a fair representation of the principal points of philosophical anatomy, as given in the writings of Owen; in many points it is very unsatisfactory, and he labors very hard oftentimes to make out his homologies and to refer them to his archetype. With such sources of error and room for variation, it would be useless to expect perfect agreement among authors; from the nature of adaptive organization, it must be difficult if not impossible to reduce skeletons and their parts to unexceptionable laws; organic systems will not be bound down to any such narrow and clearly defined rules, and are constantly presenting to naturalists instances of inexplicable departure from what have long been considered natural laws; the common fallacy that an exception proves a law plainly shows that many of our most firmly established principles in natural science are but approximations to and fragments of eternal truth. Philosophical anatomy will probably always be an uncertain and ever changing study, assisting but not constituting the science of anatomy. Admitting the 4 cranial vertebræ of Oken and Owen, there may still be recognized with as much propriety other vertebral centres in advance of the vomer, analogous to the coccyx at the other end of the column, with no nerves belonging to them. The usual reason for making 4 cranial vertebræ seems to have been, both with Oken and with Owen, the existence of 4 organs of sense in the head, auditory, gustatory, optic, and olfactory; on this principle there would seem more reason for the admission of only 3. In the first place, there are 3 cerebral vesicles, corresponding to what become cerebellum, optic lobes, and cerebral hemispheres, or according to some anatomists the *medulla oblongata* may be substituted for the cerebellum; in the next place, there are only 3 special senses in the head, hearing, seeing, and smelling, taste being a compound sense, made up of smell and touch; the flavor of substances we get from the sense of smell, as the result of a common cold in the head and of artificially preventing the entrance of air by holding the nose sufficiently show; the rest of the sense of taste is a delicate modification of the sense of touch, placed for protective purposes at the commencement of the alimentary canal; it is absent in many of the lower vertebrates, and has no more claim to be reckoned among the special senses than similar modifications of the sense of touch in the wing of the bat or in the genital mucous membrane; the origin, development, and mode of distribution of the gustatory nerve, which is only a branch of the 5th pair, moreover are not such as belong to special sense organs. There are also only 3 sense capsules in the head, the petrous portion of the temporal bone, the sclerotic in the eye (as in the tunny), and the ethmoid for the sense of smell. As each vertebra of the trunk corresponds to a spinal nerve, there ought to be, according to the view here maintained, 3 pairs of nerves in the head; excluding the 3 special sense nerves, the 1st pair of cranial nerves would be made up of the *motores oculorum*, pathetic, external motor of eye, and the facial (or the 3d, 4th, 6th, and 7th) for the motor portion, and the 5th or trifacial for the sensitive portion; the 2d pair of cranial nerves has the glossopharyngeal and spinal accessory for its motor portion and the *par vagum* for the sensitive; the 3d pair of cranial nerves is the hypoglossal, which, though all motor in man, in reptiles (*frogs*) has the sensory ganglion of an ordinary spinal nerve; in the same manner in reptiles the 7th is seen to belong to the 1st, and the glossopharyngeal and spinal accessory to the 2d series. We have, then, 3 cerebral vesicles, 3 special senses, 3 sense capsules, and 3 pairs of cranio-spinal nerves, which would seem to indicate 3 cranial vertebræ, with a rudimentary nasal or other vertebral bodies in front, without nerves belonging to them, corresponding to the coccyx posteriorly. There is no regularity in the manner in which the nerves, both spinal and cranial, come out of the vertebral canal; the 2d cranial nerve comes out at the jugular foramen, between the occipital and parietal vertebræ; some of the nerves of the 1st pair make their exit from the cranium by the *foramina rotundum* and *ovale*, and some by the sphenoidal fissure, that is, both through the 2d and between the 1st and 2d; in the human spine the nerves come out between the vertebræ, but in the dorsals of many mammals they pierce the middle of each vertebra. As to the hæmal arches, Prof. Owen finds it very difficult so to divide his tympanic series as to get the hyoid arch and lower jaw as appendages to the 2d and 3d vertebræ; there is considerable doubt as to whether the diverging appendages of the cranial vertebræ are as yet properly determined. Admitting 3 cranial vertebræ, with a rudimentary 4th or nasal centrum, let the occipital segment claim the scapular arch; the lower jaw may be appended to the parietal and the upper jaw to the frontal segment, the hyoid arch, as Carus and others maintain, being placed with the tracheal rings in the splanchnoskeleton; or, leaving the hyoid arch in the endoskeleton (which is probably more correct), and pertaining to the parietal segment, the upper and lower jaws may be made the double hæmapophysial appendages to a single rib, as the ischium and pubis are to the ilium. There are some facts favoring the latter view, such as the development of both jaws from a single arch; in the cyclostome fishes the mouth is an arch, in which it is hard to say which is upper and which is lower jaw; in *myxine* there is no under jaw, the inferior portion of the mouth being made up of the anterior part of the tongue bone. Not to multiply instances of other doubtful and debatable points, these will suffice to show that philosophical anatomy has not yet reached a positive and unassailable foundation.—Though Owen's conclusions are accepted by most anatomists as coming nearest the truth, Mr. Maclise, in the article "Skeleton" of the "Cyclopædia of Anatomy and Physiology" (vol. iv., London, 1852), looks at the osseous framework from another point of view, and comes to very different results, at only a few of which can we glance here. He denies that there is any such *ens* as a typical vertebra, and maintains that vertebræ are unequal quantities, varying in different regions of the trunk; according to him, the cervical, lumbar, and sacral vertebræ develop costal appendages as well as the dorsal; the first 7 thoracic costo-vertebral figures are complete, and all other parts of the mammalian spinal axis are more or less modified from this archetype; the mammalian cervix is not limited to 7 vertebræ, and may contain from 5 to 9 without anomaly, the number depending on how many have the ribs developed only to the cervical degree; all the spinal segments of the vertebrata are only as the variable proportionals of sterno-costo-vertebral archetypes. The hyoid apparatus consists of the metamorphosed ribs of the cervical vertebræ, and the ventral apparatus (as in the crocodilians) of those of the lumbar; clavicles and coracoid bones he regards, like ribs, as identical parts of the costo-vertebral archetype, and as belonging, not to the atlas, but to the 7th cervical vertebra; in like manner, marsupial bones, pubic and ischiatic bones are rib-like in their nature, and belong to the lumbar and sacral vertebræ. In the head he makes 6 vertebræ: 1, occipital, the rib and sternum being the styloid process and the upper half of the hyoid bone with its lesser cornu; 2, petrosal, with its costo-sternal quantity the tympanic bone coiled upon itself and enclosing the bones of the ear; 3, temporal, having no centrum, but the temporal and parietal bones for neural arch and spine, the lower jaw articulating like a rib to the glenoid cavity; 4, post-sphenoid, with greater sphenoidal wings for neural arch, and the zygoma and upper jaw for rib and sternum; 5, anterior sphenoid, with lesser wings for neural arch, and palate bone for costo-sternal portion; and 6, ethmoidal, with the ethmoid for centrum, frontal for neural arch, and nasals for rib and sternum. The lower portion of the hyoid bone with the greater cornu is the sternal quantity and rib of the atlas, the thyroid cartilage of the axis, the cricoid of the 3d cervical, the tracheal rings of the 4th, 5th, and 6th, and the clavicle of the 7th cervical. He makes out these 6 cranial vertebræ also from the disposition of the nerves; as in the spine a nerve passes between 2 adjacent vertebræ, and 5 nerves would correspond to 6 vertebræ, he finds 5 cranial nerves for his 6 cranial vertebræ; the 1st nerve is the olfactory; the 2d, a group containing the optic, 3d, 4th, and 6th nerves, motor and sensory, passing through the *foramen lacerum;* the 3d, branches of the 5th passing through the *foramen ovale;* the 4th, the auditory and facial; and the 5th, the par vagum, glossopharyngeal, &c. The fore limbs are homologous to one another and to the posterior limbs; the scapula and ilium are the homologues of the posterior laminæ of a dorsal vertebra, the acromion and inferior iliac spinous processes correspond to transverse processes, and the head of the humerus and femur to the head of a rib.

PHILOSOPHY (Gr. φιλος, loving, and σοφια, wisdom), the universal and absolute science, aiming to explain phenomena by ultimate causes; to grasp the nature of real as distinguished from phenomenal existence; to systematize the forces and the laws which prevail in the activities of God, man, and nature; to reduce the universe to a principle of unity; and to exhibit at once the impulse and the goal of destiny. The origin of the name is, upon questionable authority, attributed to Pythagoras, who preferred to be called a philosopher, or lover of wisdom, rather than a sophist or sage. It was appropriated and first popularized by Socrates, who made it the distinctive appellation of his teaching in contrast to the arrogant designation of the sophists. Originally assumed in modesty, the term did not retain its etymological and Socratic meaning, but returned to that of σοφια, or wisdom. Among the most significant definitions of philosophy are the following: "the knowledge of things divine and human" (attributed to Pythagoras); "a meditation of death" (μελετη θανατου), and "a resembling of the Deity in so far as that is possible to man" (Plato); "the art of arts, and science of sciences" (Aristotle); "that part of human learning which hath reference to the reason" (Bacon); "the science of things, evidently deduced from first principles" (Descartes); "the science of effects by their causes, and of causes by their effects" (Hobbes); "the science of sufficient reasons" (Leibnitz); "the science of things possible in so far as they are possible" (Wolf); "the science of the connecting principles of nature" (Adam Smith); "the science of truths, sensible and abstract" (Condillac); "the science of the relations of all knowledge to the necessary ends of human reason" (Kant); "the science of the original form of the Ego, or mental self" (Krug, with which that of Fichte substantially agrees); "the science of the absolute, or of the absolute indifference of the ideal and real" (Schelling); "the science of reason, in so far as the latter is the conscious idea of universal being in its necessary development" (Hegel); "the substitution of true ideas, that is, of necessary truths of reason, in place of the oversights of popular opinion and the errors of psychological science" (Ferrier); "the knowledge of effects as dependent on their causes" (Sir William Hamilton); "the science of first principles, that, namely, which investigates the primary grounds, and determines the fundamental certainty, of human knowledge generally" (Morell); "the science of the ultimate principles and laws of nature and freedom, as also of their mutual relations" (Tennemann); "the science of the reason of things" (Alaux); "the explanation of the phenomena of the universe" (Lewes).—Philosophy agrees with religion in revealing the infinite, in regarding individual objects as products or shadows of an ultimate absolute principle. But it requires evidence and logical sequences, while religion rests upon mystery and faith, upon instinctive and spiritual certainty. The one systematizes the totality of things in the domain of knowledge, the other in that of feeling. In the order of history religions are the preludes of philosophies. The former divinize phenomena, the latter establish between them relations of cause and effect. Faith grasps the substance, reason furnishes the form. The mode of conception and statement in the two are entirely different. Philosophy gives *explicite* the abstract ideas and tendencies which are involved *implicite* in the conceptions of religion. Poetry or art also, like philosophy, is a revelation of the infinite; but its ideal is beauty, while that of philosophy is truth. The one moves according to principles of taste, the other by logic; the law of the former is the imagination, that of the latter the reason. A complete philosophic system may have an æsthetic character, and a finished work of art may be analyzed as philosophy analyzes the universe; yet if each were perfect, the former would be abstract and absolute, the latter would be concrete, an imitation, but not an explanation or a justification, of nature. Philosophy, as the science of ultimate principles, differs from special sciences whose objects are finite phenomena and proximate causes. It transcends them, and deals with objects only in the light of the absolute. Even the whole circle of the natural sciences does not constitute a system of philosophy, which, if empirically established at all, would only be so by combining the results of all departments of scientific inquiry as the basis of a higher generalization. Each particular science seeks a principle of unity, a force and law which will account for the phenomena in its own realm. This principle becomes an element in universal science or philosophy, which seeks after absolute unity. The individual has the ground of its existence in the species, the species in the genus, the genus in some broader classification, and so on till an ultimate substance be reached, from which all things are developed, and which is the goal of philosophy. The final attainments of the sciences are the elementary data of empirical philosophy. Yet philosophy, in its higher manifestations, has not started from the results of science, but from the suggestions of consciousness and the postulates of reason.—Philosophy embraces the two departments of psychology, which investigates the faculties and operations of the human mind, and ontology, which seeks the nature and laws of real existence. The former deals with the phenomena of consciousness, the constitution of the mind, the laws of thought; the latter with the essential characteristics of being *per se*, the constitution of the universe, the laws of things. The former is descriptive, and the latter scientific metaphysics. The transition from the one to the other, the demonstration of objective reality from subjective conception, is the leading philosophical problem. The aim of psychology is the description and analysis of mental experience. Even when combined with logic, it can furnish a knowledge only of phenomena and relations. It marks, first, the changing facts which succeed each other in the mind; secondly, the faculties or permanent powers to which these facts are severally related; and thirdly, the affirmation of personal existence and identity. The multiplicity of facts are all manifestations of powers of thought, feeling, and volition; and these powers are the diverse operation of a simple personal principle which we accept as an axiom of consciousness. *Cogito, ergo sum,* the Cartesian proof of personality, of the distinction of one thinking being from every other, remains true, though the mind be regarded as a collection, not of faculties, but of sensations, as by Condillac, or of impressions and ideas, as by Hume, or of categorical laws, as by Kant. The phenomena of consciousness, however classified, are usually distinguished as sensitive, intellectual, and volitional. To the first class belong sensations and emotions, the former an affection through the body, the latter through the mind. To the second class belong perception through the organs of sense; conception, when these organs are not concerned; memory, which is conception with individual recognition; imagination, by which conceptions are combined in a different order from any in which the originals were perceived; belief, with or without evidence; and reasoning, which is either contingent or demonstrative. To the third class belongs only the act of willing, but as this may be exerted in the control of other mental operations, there results a new class of mixed intellectual and voluntary operations, as attention, abstraction, comparison, classification, generalization. The term ontology, which by present usage means the same as the ancient metaphysics, was first introduced into philosophical language by Wolf to designate the primary department in his quadruple classification of philosophy—psychology, cosmology, and theology being the other three. He intended by it the science of abstract (not absolute) as distinguished from real being, the science of the possible, of the necessary and contingent, of quantity and quality, of substance and accident, &c. It expounded rational laws, without reference to whether any thing actual obeys them, or to the laws of intellect by which we believe them. Kant condemned under this name the whole theory that our subjective ideas imply real objects, veritable existences, corresponding to them, and particularly confuted the ontological proof of the divine existence. From his time ontology has been opposed to psychology, and comprehends investigations into every real existence, which, without being a direct object of consciousness, may be deduced from the possession of certain feelings, or principles, or faculties of the human soul. Its three objects are the soul, nature, and God, to which correspond Kant's three ideas of pure reason, and the three departments of rational psychology, cosmology, and theology. Its goal is an organic system of the spiritual and material universe, an intuition of unity. The whole modern philosophy of the absolute is ontological, while positivism denies that we can pass beyond the phenomenal, and Sir William Hamilton denies that we can be scientifically certain that our faculties adequately represent objective realities. —Every system of philosophy is the speculative development of a principle, a coherent chain of thoughts, whose first member is accepted as an axiom, and whose last is the remotest consequence resulting from it. Between the two lie all the phenomena of the universe and of human life. Systems develop progressively what the reason contains as a possibility and demands as an ideal. The adherents to the method and tendency of a system constitute a school of philosophy. The system is developed by analytical or synthetical processes, according as the goal to which it tends or the axioms from which it proceeds were first apprehended by the mind. A principle being given, synthesis unfolds it till it takes in the totality of things in its consequences. A result being assumed, analysis considers the road which must be followed and the premises which must be framed to justify it. The order and direction of ideas are diametrically opposite in the two procedures. If the thought be analytical, the guiding point is a problem, a goal hovering before the mind to be attained at all events. If the thought be synthetical, the guiding point is an axiomatic premise, and the course of ideas is but a series of legitimate conclusions. The former method is that of solutions, the latter that of deductions. They are counter-processes, correcting each other, analysis being properly the foundation and synthesis the conclusion of philosophical thought. Historically the latter usually precedes the former, furnishing the preconceived hypothesis which guides analytic researches and which is confirmed or corrected by them. Boldness in synthesis has been more common than precision in analysis. "With regard," says Samuel Bailey, "to the philosophy of mind, which must always constitute the foundation of non-physical science of every description, I venture to repeat the prediction that no great progress will be made by those who prosecute it, and that they will continue to move in a circle, until they consent to do what successful physical inquirers do, namely, to dismiss all figurative statements of fact, all fictitious entities and occurrences, all abstractions except as mere forms of expression, all hypotheses except such as may be professedly put forth in the character of tentative suppositions; and to confine themselves to real objects, actual events, literal statements, and rigorous conclusions." Carus describes the history of philosophy as "the natural history of the human reason, its pursuits and products." It presents a genealogy of systems, and shows the progress of reason through abstract schemes like that of the soul through successive religions and civilizations.—It is a peculiarity of Indian speculation that it esteems life the greatest of evils, and looks to annihilation as the highest bliss. To extinguish individuality in absorption, to close the circle of metempsychosis, to be finally rid of being, is the goal to which both religion and philosophy point. The orthodox and probably oldest system of Hindoo philosophy is that of the Vedanta or the Mimansa. It embodies traditions of Brahminism, interpretations of the Vedas, and results of speculation. The second Mimansa, which is specially called Vedanta, develops the idea of Brahma as at once the operative and material ground of the universe, both the principle and the result of creation, both immanent in the world and transcendent above it, both the source and destiny of all things. Return into Brahma and blissful extinction is the desire and goal of all souls. Unable to determine the relation between Brahma and the world, abstract essence and concrete nature, being and becoming, rest and movement, unity and multiplicity, Indian philosophy divided into two schools, which respectively maintained Brahma and the world as the only real existence, each excluding the other. According to the Vedanta, the world is a delusion, a phantom, like the image of the moon on water; the senses are deceptive, and Brahma alone exists. The phenomenal universe is the mistake of our own eyes, and our subjective conception of self or of any distinction between the person knowing and the thing known is in like manner false. The wise man escapes from the snare of this distinction, and from all unreal appearances, and rises to unimpassioned repose, pure contemplation, transcendent freedom, to union with Brahma. He becomes conscious of himself only as the changeless, eternal, and universal Brahma, and the whole circle of individual life, birth, old age, and death, is to him but a phantasm. Asceticism is the ethical result from this theory. The Sankhya philosophy, whose mythical founder was Kapila, is the rationalism of Brahminism, and starts from the dualism of spirit and matter, unlike the Vedanta, which identifies subject and object. It regards spirit not as the pervading soul of the world, but as an infinitude of individual souls, which from the beginning have acted in union with nature. Every soul, when it has once penetrated the mask of material things, and discovered its own absolute independence, attains a pure gnosis, but may continue to exist though its end be gained, as a wheel may still roll after the impulse has left it. Thus illumined, however, it obtains a final and absolute liberation from life at the death of the material body; but of its former condition, whether any conscious or unconscious personality remain to it, nothing is said. As the Vedanta doctrine proceeds from the idea of abstract unity and substance, the Sankhya proceeds from the data of individual consciousness, from the antagonism of the individual soul and nature. The former declares the phenomena of this antagonism unreal and delusive; the latter denies an all-absorbing divinity. The goal of the soul, according to the one, is absorption into Brahma, and according to the other, escape from nature. In either case, the soul once free is subject to no further peril of existence. Beside these two principal systems, there are the Nyaya (logic), the atomistic Vaiçeshika, and the later Yoga, which aimed to unite with the Sankhya theory the idea of a creative Deity. The Nyaya, ascribed to Gautama, though it contains no account of the syllogism and is but a superficial code of ratiocination, has had an influence on all the schools of India corresponding to that of the *Organon* of Aristotle on western philosophy. The Vaiçeshika regards the universe as composed of eternal atoms, which it reduces to 6 categories, 9 substances, 24 qualities, and 5 movements. The Yoga is a system of mysticism, inculcating the union of the individual with the infinite soul in contemplative ecstasy. The whole Indian philosophy has in connection with its ontological doctrines a psychology of remarkable subtlety and obscurity. In no other country has the struggle between matter and spirit, sense and reason, been more strikingly characterized. Spirit and reason triumph, but only to extinguish every finite personality in one infinite life.—The basis of Chinese philosophy is the book of principles (*Y-King*, "Transformations") attributed to Fu-hi. The lines which he is supposed to have inscribed on the back of a dragon are abstract categories of the ethical and physical worlds. A continuous straight line represents the heaven, and a broken line the earth, and their combination according to a numerical law explains all things. The senses thus triumph in the efforts of the reason, making a system of linear symbolism. In the 6th century B. C., Lao-tse and Confucius became the chiefs of opposite schools. The former, from the hypothesis of a primordial unity, explains the origin and destiny of beings by a scheme of pantheism; the latter, avoiding purely speculative questions as inaccessible to the reason, sought only a practical philosophy as a means of moral perfection. Preeminent among the disciples of Confucius was Mencius. His precepts were founded on no theory of virtue, and had no reference to a divine power. A school of Neo-Confucianism was formed about the 10th century, the founder of which was Tcheu-lien-ki, and the chief Tchu-hi, which treated specially of cosmology. An original principle, having both active and passive modes of being, and generating the 5 elements, fire, water, earth, wood, and metal, from which all things proceed, is the fundamental conception of the system. Man is the flower of creation, but though his soul returns to heaven after death, it loses its personality. The whole Chinese philosophy seems but the effort of a prosaic people to give a light-and-shadow sketch of the more palpable facts of heaven, earth, and man.—The Persian dualism and the Hebrew monotheism belong to the history of religion rather than philosophy; and the wisdom of the Egyptians is known to us chiefly from its supposed influence on Greek speculation. In Greece first, says Hegel, was the light concentrated into the lightning of thought. The first problem of Greek philosophy was to explain the enigma of external nature, to account for the spectacle of the material universe, to solve the problem not of the soul but of the world. By an imperfect analysis some hypothetical element was attained, which by a hasty synthesis was integrated into the principle of all things. The Ionic and the Italic schools, which on opposite sides of the Greek peninsula opened the series of Hellenic speculations, embodied this tendency. Thales of Miletus (about 600 B. C.), the first of the Ionic philosophers, made water the primal and universal principle, the fundamental agent in creation and movement. He thus conformed to the poetical tradition that "Oceanus is the father and Thetis the mother of things," but has the merit of advancing from a mythical to a scientific representation. His disciple Anaximander assumed as the original essence an ethereal principle, filling space, which by successive combinations constituted the universe. He seems only to have given a philosophical expression to the conception of chaos in the old cosmogonies. Anaximenes, the third of the Ionic sages, made air the original element, from which by rarefaction and condensation he derived all things. Thus water, an original chaotic matter, and air were the three substrata to which Ionic speculation attained as the ultimate principles of unity and goals of philosophy. The Italic school, represented by Pythagoras (540-510 B. C.), advanced from a sensuous to a symbolical principle. Number is made the essence of the mental and material universe. The occult relation of numbers is the key to philosophical attainments. The harmony of the universe and the music of the soul are the highest objects of knowledge and culture. Thus the relations and harmonies of existence take the place in Italic speculation which had been occupied by substance and cause in the Ionic. The latter, also, limited itself to physical nature, while the former reduced the moral and material worlds alike to a principle of rhythm. Another step in advance was taken by the Eleatics, who, transcending both a sensuous and a symbolical ultimate principle, conceived of one sole substance as the only true being, and pronounced the phenomenal world an empty appearance. An immutable and eternal principle of intelligence was thus attained. "One and all," was the motto of Eleatic speculation. Its pantheistic character, incompletely developed in Xenophanes, who conceived of the Deity as symbolized by a sphere, was perfected by Parmenides (460 B. C.), who represented the absolute being as affected by love, yet without relation to space or time, divisibility or movement, and who therefore could not account for the phenomena of multiplicity and change. Melissus and Zeno continued this tendency, and in the interest of pure being sacrificed nature and all finite existence. The transition from abstract to concrete being, from the Eleatic principle of unity to the world of phenomena, was attempted by Heraclitus (about 520 B. C.). "Every thing flows," was his motto, and he thus introduced a principle akin to the German conception of becoming (*werden*). An original energy was substituted for the Ionic original matter and for the Eleatic universal but abstract being. The flux, which constitutes the world, is the product of conflicting opposites, of the One warring with itself and harmonizing with itself, like the accord of the bow and the viol. An all-pervading fire is the principle of formation and dissolution. The attempt to account for perpetual flow and movement gave rise to new theories of the origin and principles of nature by Empedocles (440 B. C.) and the atomists. The former, a thaumaturgic naturalist, originated the theory of the 4 elements, fire, air, earth, and water, which dwelt together by the principle of friendship, till strife broke their union, and occasioned the formation of the world. Thus in connection with the elements he introduced two moving powers, combining the love of Parmenides with the conflict of Heraclitus. The soul he regarded as formed from the 4 elements, and having its seat chiefly in the blood. Leucippus and Democritus (about 400 B. C.), who represent the atomic philosophy, supplanted the 4 elements by an unlimited number of constituent atoms as the ground of things, and the moving energies of love and conflict by unconscious necessity. Atoms, of like quality but unlike form, moving eternally in a vacuum by an absolute law, constitute the universe. According to Democritus, the soul consists of globular atoms of fire, and thought is derived from impressions on the senses by images that emanate from external objects. "Parmenides, Heraclitus, and the atomists," says Hegel, "all sought for the abstract universal. Parmenides found it in being; Heraclitus in the process of being *per se*; and the atomists in the determination of being *per se*." The atomic system was more complete than any that preceded it, and may be called the perfection of a purely mechanical explanation of nature, since all subsequent atomists have only repeated its fundamental conceptions. Anaxagoras (born about 500 B. C.) rose above any materialistic philosophy of nature, and recognized by the side of matter a superior world-forming intelligence, working freely and by design. "When," says Aristotle, "he announced that in nature, as in men, there was a mind causing the arrangement and order of the universe, he seemed alone to have preserved his reason amid the follies of his predecessors." He rather postulated than developed the doctrine of mind as the superior and vital energy of nature; and Plato therefore complains that he gave a mechanical instead of a truly teleological view of the origin of being, introducing only a *deus ex machina* to explain effects for which no other causes appear. Yet a spiritual principle, apart from matter, was now attained as the result of the effort to conceive how the cosmos began and continued to move. A breach was thus effected between the subjective and the objective; the soul no longer sought the truth abroad, but in itself; and the sophists were able by subjective dialectics to deny objective reality. Though the sophists were, according to Grote, a profession of teachers and not a sect of theorists, and though they had no body of common doctrines, yet the general tendency of their speculations was sceptical. With the motto of Protagoras that "man is the measure of all things," they developed the principle of subjectivity to the destruction of the authority of custom, law, and religion, the validity of reason, and any solid foundation of truth. While they tended to overthrow the whole edifice of thought which had been thus far built up, Socrates (470-399 B. C.) created a new epoch in philosophy by directing observation on man himself for the purpose not of denial but of affirmation. The subjectivity which they regarded as empirical he made absolute; and henceforward the study of mind became the prime and central object of philosophy. He availed himself of self-consciousness to establish, as they had done to destroy, a true objective world. Hegel has remarked that in pronouncing Socrates the wisest of men the Pythia virtually abdicated; from that time oracles for the conveyance of truth from without should be silent before the power of inward reflection. Confining his study to human as distinguished from divine affairs, he sought to establish the notions of moral and religious obligation, and left the single positive doctrine that virtue is knowledge or wisdom, a foundation stone in the scientific treatment of ethics. He gave to philosophy definition and induction as its method, self-knowledge as its point of departure, and moral perfection as its goal. His partial disciples were Antisthenes and the cynics, Aristippus and the Cyrenaics, and Euclid and the Megarians. Each of these adopted from him the principle that all men should have one supreme aim after an ideal perfection. The cynics sought after a life according to nature, in contempt of customs, arts, sciences, and even personal wants; the Cyrenaics made it the chief end of man to follow the instinct of pleasure, making present enjoyment the test of wisdom and virtue; and the Megarians applied Eleatic dialectics to ethics. These schools prepared the way respectively for Epicureanism, stoicism, and scepticism. The interpreter of the Socratic philosophy, the first who attained to a systematic representation of the world of ideas, was Plato (430-347 B. C.). Beginning with the soul, as an independent existence, he distinguishes in it two components, the divine and the mortal, the reason and the appetites, which are united by an intermediate link, the heart (θυμός) or generous sentiments. The activity of the soul culminates in the pure thought of the reason. To explain its connection with matter, he refers to its origin. In the beginning, in the choir of gods, it moved happily around the divine essence, in the contemplation of which it delighted. Misled and fallen, it lost its wings, and is confined in the body as a place of expiation. Still, amid the miseries of the present life, it sometimes recalls dim reminiscences of its former state, of the truth and melody in which it then lived. All philosophy is reminiscence. The earth is as a cavern open on one side to the light, in which the prisoners only see the shadows and hear the echoes of the voices of the persons without. The luminous external region is the region of ideas. By purification and discipline man rises through opinion, belief, and rational knowledge to that pure intuition which introduces to this higher realm. The culture of the sciences, of geometry, astronomy, and music, is preliminary to dialectics, whose function is to distinguish what is phenomenal and accidental in things from what is essential, permanent, and ideal. It thus grasps beneath the current of phenomena the types which are eternal. The highest idea, and the ground of all other ideas, is that of the good, at once moral and metaphysical, which is the goal of thought, as the idea of the beautiful is the goal of love. The Deity is the architect of the world, which he has fashioned in his likeness, making it an organism of order and beauty. Man, also, should aspire after resemblance to God, and should reflect the divine ideas in his own works. In a polytheistic age and country, Plato placed a paternal Providence; while his contemporaries wasted their energies in the sterile contemplation of phenomena, he revealed divine types; amid thinkers who were certain of nothing, he was the preacher of immortal being. His theories have reappeared in special power whenever the human mind has risen from repose or from errors to advance to a higher stadium in its progress.—While Plato esteemed only abstract types, Aristotle laid stress on concrete individualities, assailed the theory of ideas as baseless and fantastic, and proposed instead the theory of causes. He recognized four metaphysical causes or principles, matter, form, motive power, and end, which all resolve themselves into the fundamental antithesis of matter and form. The form, which is life, being added to matter, to which also is ascribed an element of desire, transforms potentiality into actuality; thus a statue results from matter in the quarry and form in the mind of the artist, and nature is but an evolution of the forms of divine intelligence. These forms, unlike the Platonic ideas, are not accomplished, self-subsistent, and permanent entities, but constitute at once an eternal energy or entelechy and its eternal product. The actual does not follow but coincides with the potential; the form or essence of nature is nothing else than the way to nature, its realizing activity and also its proper end. The ideal and real elements which Plato had set apart were thus closely bound together. Forms, as motive principles pervading the universe, have their source in God the first mover, who is being in perfect activity, and bears nothing in himself which is merely potential. As Platonism culminated in the conception of ideas, Aristotelianism culminated in that of motion, energy, or life, working in all things, and the ground of their existence and development. Reality belongs only to particulars; complete knowledge requires complete experience; but all possible determinations of being are contained in 10 categories, their relation to which may be discovered by syllogistic reasoning. The Aristotelian system of logic was scarcely improved until the present century. The systems of Plato and Aristotle are illustrious examples of the ideal and real, or *a priori* and *a posteriori* schools, which have existed in every age of speculation.—The decline of the Greek spirit and civilization was marked by three systems of philosophy, conceived with indifference to speculative truth. The scepticism of Pyrrho denied the possibility of certitude concerning any thing objective, and proposed a thoughtless and aimless acquiescence in the impulses of nature as the law of life. His system was maintained by the leaders of the new academy, Arcesilaus and Carneades, and anticipated the absolute doubt of Ænesidemus and Sextus Empiricus. Epicurus proposed as the goal of philosophy a scheme of morals that should inevitably lead to happiness. The aim of his physics was to rid mankind of the terrors that come from belief in God and immortality, and the aim of his logic was to banish the troubles that come from error. The universe is an aggregation of atoms, moving by chance; the soul terminates with death; and in a remote space the gods lead a changeless, careless life, ignoring all management of affairs. Plutarch reproached this system with total sterility of great men and great actions. Stoicism, on the contrary, was recommended by its heroes. Founded by Zeno, and developed by Cleanthes and Chrysippus, it sought to establish a discipline of virtue in an age of degeneracy. Assuming that all the materials of knowledge are furnished by sense, it maintained that assent or the free exercise of reason is also required to constitute opinion, and thus proposed a subjective criterion of truth. Nature is composed of passive matter and active ruling reason, and to live harmoniously with nature or conformably to reason is the moral law. Intellectual or rational existence is thus alone recognized; passions, pleasures, and pains are to be ignored and despised.—The Romans, to whom the results of the Greek schools were made known by Cicero, originated nothing in the progress of philosophy. Epicureanism was represented among them by Lucretius, and stoicism by Seneca, Epictetus, and Marcus Aurelius, but neither acquired new speculative elements: the former inspired the lower, and the latter, which was an anticipation of the national genius, inspired the higher qualities of Roman life. Seeking only a rule of conduct and government, excelling only in the arts of legislation, they aimed to apply rather than discover principles, and borrowed the ideas not only of Greece, but also, through the Ptolemies and Seleucidæ, of Egypt and Asia.—In Alexandria, where the Orient and the Occident, and the three great religions, Judaism, Christianity, and paganism, came into contact, the genius of antiquity made its last efforts in philosophy. The leading systems had degenerated into matters of tradition and erudition, when the Alexandrian Neo-Platonic school sought to combine in opposition to Christianity the most brilliant elements of classical and oriental speculation. Hellenic ideas were mingled with a vague symbolism, with theories of ecstasy and divine union, and with the chimeras of theurgy. The result was at once a philosophy and a religion, an original creation and an eclectic *résumé*. Founded by Ammonius, it continued nearly 4 centuries, till with the death of Proclus, in A. D. 485, the golden chain of the Platonic succession was finally broken. Its chief thinker was Plotinus, whose writings contain the germs of the whole doctrine ascribed to Orpheus, Pythagoras, and Plato, and who was a Platonist in method, a mystic in temper, and a pantheist in his results. He was succeeded by Porphyry and Iamblichus, who sought from polytheism and demonology magical powers and religious inspiration for the revival of philosophy, and who made the school the centre and representative of paganism on the eve of the conversion of Constantine. The fruitless career of Julian, the fate of Hypatia, the vigorous controversies of the fathers of the church while the philosophers occupied themselves with commentaries, had proved their cause to be desperate, when Proclus made the last protest against the triumphing religion. Philosophy had now transferred its seat to Athens. He was a type of the luxury of mysticism, and amid the severest asceticism, while insensible to outward impression, avowed that his imagination enjoyed all the delights of sense. His system, like that of Plotinus, confounds man and God, matter and spirit, nature and the creator. He admitted and admired an original and perfect unity, but declared it superior to existence, and separated it from reality and life, reducing it to an abstract conception. The origin of the world he explained by hypostases distinct from this supreme principle. The most eloquent of hierophants, rather than a philosopher, he has been called the pontiff of all religions, and, excepting the Christian, he sang the praises of all gods. Greek philosophy terminates with the closing of the schools of Athens by Justinian in 529.—The period of the scholastic or mediæval philosophy has been called an interregnum in the history of the human mind, when faith occupied the throne of reason. Two distinct currents run throughout scholasticism: the one, rigorously logical, derived from Aristotle and Boëthius; the other, wholly mystical, derived from the Neo-Platonists of Alexandria and Athens through Scotus Erigena and Averroes. In religious and social influence, in general dominance over the habits of thought and life, mysticism was the leading element in the middle ages. After the closing of the schools of Athens by Justinian, and the dispersion of the philosophers, Arabia and France became the centres of philosophical speculation. Philoponus, Damas, and other peripatetic Christians presided over the intellectual development of the Arabians, and interpreted to them the writings of Aristotle. The patronage of the caliphs Haroun al Rashid and Almamoun, about the time of Charlemagne, made the Arabians preeminent for scientific studies. As learned Aristotelian logicians Alkindi (800) and Alfarabi (died in 954) excelled. Al Ashari and his disciples sought to solve the problem of evil by the synergy of the divine and human wills. Avicenna is the principal representative of the physical speculations of the Arabians. Applying to the universe the forms of logic and metaphysics, he developed a fantastic system founded on a sort of alchemistic mysticism. Certain material abstractions were made the principles which by combination and by clothing themselves with accidents evolved the physical world. Algazzali, an absolute sceptic, and also one of the most zealous Mussulman theologians, denied the foundation of all philosophical systems whatsoever, and affirmed that the revelation of the Koran was the only resource against universal doubt. All of these reproduced peripateticism in different phases, but the oriental mystical tendency prevailed in other thinkers. Tophail of Cordova wrote a romance entitled the "Man of Nature," the hero of which rises through many degrees of contemplation to a union with the Deity. Averroes explained the origin of things by the doctrine of emanation, each object developing its form from an inward germ, and distinguished in the soul the active and the passive intellect, the former of which knows universal truths and is a common substance in all men, and the latter deals with material phenomena and is a special substance in each man. Thought is a product from the union of these two faculties. Theology he regarded as an expression of relative truth, of vulgar beliefs, while to philosophy alone belonged the province of absolute truth. Some of his doctrines were developed by his disciple, the Jew Maimonides. The Mussulman theologians declared that the philosophic schools were of fatal injury to religion, and the philosophers maintained against all the sects the eternity of matter and the limitation of the divine knowledge to the general laws of the universe. The speculations of Arabian scholars transmitted the forms of the Aristotelian logic, with which Christianity next came in contact after its conflict with Neo-Platonism. Scholasticism, a philosophy of dogmas, resulted from this synergy of faith and reason, and dominance of the former. Its elements were doctrines which the authority of the church made indisputable, and which were esteemed absolute truth; its aim was to interpret, not primarily man or nature, but the creed, to give to the contents of revelation a scientific form; and its method consisted in drawing inferences from acknowledged statements, and accumulating distinctions concerning words. Propositions were substituted for the *a priori* numbers, ideas, and forms of ancient philosophy, and syllogistic reasoning, founded on them as premises, became the only instrument for the discovery of truth. The facts of nature were overlooked in the development of an artificial logical scheme; and Roger Bacon alone seems to have regarded experiment, even in physics, as fit to precede and guide rather than to follow and illustrate theories. The objective world had lost its dominance in philosophy with the decay of the Hellenic life, the mind was turned back upon itself, and the problem of being was raised under the form of questions concerning the nature of our ideas of universals and individuals. The first period of scholasticism, from the 9th to the 11th century, represented by Erigena and Anselm, displays a blind but absolute realism, holding to the objective reality of generic ideas. Erigena by his unrivalled erudition, which is supposed to have included an acquaintance with Indian speculations, gave the impulse, and Anselm by his motto, *Credo ut intelligam*, gave the direction, to philosophical thought. The latter first proposed the ontological proof of the divine existence, founded on our idea of infinite perfection, which was afterward revived by Descartes. In the second scholastic period, extending to the 13th century, Roscellinus combated Anselm by ascribing to every generic or universal idea only a verbal reality, affirming it to be a vain abstraction of the mind, and thus introduced the controversy between the nominalists and realists, which Abelard sought to reconcile by the doctrine of conceptualism. Hugh and Richard de St. Victor and St. Bernard indicated a mystical tendency, a reaction against the reigning dialectics, while Peter Lombard, the "master of sentences," appealed to positive studies, collecting extracts from the church fathers without attempting to solve difficulties, and John of Salisbury ridiculed the current abuses of logic. The classical period of scholasticism was the 13th and 14th centuries in which flourished its two greatest masters, the Dominican Thomas Aquinas and the Franciscan Duns Scotus, in which realism was triumphant, and in which the Arabico-Aristotelian system was completed. The entire works of Aristotle were now first introduced from Constantinople. In discussions whether universals existed *in posse* or *in esse*, and concerning human liberty and the grounds of virtue, the Thomists exalted the understanding as the highest principle of the mind, and the Scotists exalted the will or the power of determining universals to particulars. To this period belong Alexander of Hales, Albertus Magnus, and the mystic Bonaventura. Nominalism was revived by Occam, and by distinguishing thought from being, and separating the theoretical from the practical, its effect was to give to philosophy a wider range and freer spirit. Amid the discussions of this later period of scholasticism, Raymond Lully cultivated a cabalistic natural science, under the forms of a mechanical logic, and Tauler and Gerson took refuge from the disputes of the schools in religious mysticism. The fruitlessness of the scholastic method as a means of discovery, and its inability to contain and systematize the growing knowledge of physical and historical facts, was the occasion of its overthrow. The transition to modern philosophy is marked by three classes of reformers, with respectively ideal, empirical, and mystical tendencies. To the first belong Ficino, who revived Platonism at Florence, Ramus, an able and violent opponent of the Aristotelian logic, and Giordano Bruno, the most interesting thinker of his age, who with the genius of a poet and wit as well as philosopher reproduced the Alexandrian pantheism. To the second belong Telesius, who maintained that heat and cold are the only immaterial and active principles, Pomponatius, and especially Campanella, who with mingled irony and seriousness aspired to reform every art and science, and to give to them a foundation in metaphysics. To the third belong Agrippa, Paracelsus, Van Helmont, Cardan, and Robert Fludd, who advanced experimental knowledge by alchemistic researches. Most of these precursors of a new philosophical era were remarkable for their passionate and adventurous characters and their profound enthusiasm for the wonders and secrets of nature.—Modern philosophy is related to that of the middle ages as the Greek philosophy was to that of the Orient. The oriental abstract divinities of nature-worship were succeeded in Greece by the culture of individual humanity, and the fantastic conceptions of mediæval metaphysics were finally supplanted by a vigorous observation of mental processes. Modern philosophy begins with doubt, doubt so complete that nothing remains certain but the doubt itself or the energy of conscious thought. Two systems result, empiricism and idealism, according as the objective world or the thinking subject, experience or consciousness, be advanced as the test of certainty. Bacon and Descartes stand at the head of these systems, the development of which in a double line was the task of philosophy till the time of Kant. Francis Bacon, the greatest philosopher of England, holds the same relation to empiricism that Descartes holds to dogmatic idealism and Kant to the developments of the critical school. In an age of physical discovery, he proclaimed that the intellectual world like the material world should be advanced beyond its former boundaries, and that discovery, by which alone knowledge is increased, should be reduced to a method instead of being left to chance. This method is induction, the key of natural philosophy, which from a comparison of similar instances ascertains the essential conditions of phenomena, and thus derives axioms from experiments. He treated human knowledge not as a science, but as an art, whose object is to extend and establish the dominion of man by the application of physical forces to human purposes. There is no such application without discovery, no discovery without philosophy or an acquaintance with the laws of things, no philosophy without natural science, no natural science without an interpretation of nature; and this can be accomplished only according to the measure of our experience. Nature, he maintained, had previously been anticipated instead of interpreted; conceptions and judgments had preceded actual experience; and science had, therefore, remained occupied with sterile speculations. These anticipations of the mind he names idols, the *ignes fatui* of science, which should for ever be discarded. He thus substituted nature and observation for ideas and logic; made utility instead of theory the object of research; opposed efficient to final causes, and individual things to generic notions; and denied every thing that would render an interpretation of nature teleological, idealistic, or abstract. Throughout his writings, experience is taken for granted; the first question of all philosophy as to how we know, and whether we can know any thing, was not asked by him. He gave a new direction to thought, but he neither created nor aimed after a definite philosophical system. The empiricism which he founded was heightened in its sensualistic and nominalistic tendencies as it logically advanced, and at last resolved itself into scepticism. According to him, all the sciences, even morals, politics, and religion, were to be founded on natural science, which was thus made the basis of the whole moral world. The development of this view, the derivation of moral and civil order from the natural state of man, was the task of Hobbes, the politician of the Baconian philosophy. To gather discovery from experience was the goal of Bacon. Locke began with inquiry as to the nature of experience, and how it can be attained by the human mind. The problem of knowledge was thus raised by him. Bacon had affirmed that to think correctly we must first get rid of all preconceived notions; and Locke compared the human mind prior to experience to a *tabula rasa*, perfectly void of ideas. From original emptiness nothing can proceed, and human culture therefore arises from external influences. We perceive outward objects, according to Locke, by sensation, and the consequent action of our own mind by reflection. No idea is possible unto us except through these two sources. We can therefore perceive only the outward qualities, never the intrinsic nature or substance of things, and can affirm the objectivity only of the primary qualities of bodies, as form, number, hardness, and softness, and of the causal connection of phenomena. Though not always logically consistent, his empiricism was rigidly carried out by his successors, and both parts of the residue of human knowledge which he had aimed to secure were, one after the other, abandoned. Berkeley denied the primary qualities, and Hume the principle of causality. Though the philosophy of Berkeley bears the name of idealism, it belongs to the family of sensationalism, and has no resemblance to Platonic speculations. He agreed with his predecessors that we perceive not things in themselves, but only their copies in the mind; but he differed from them by affirming that there are no real originals behind the copies, that all seemingly objective qualities are mental phenomena. Nothing exists but our perceptions or ideas, and thus nature is resolved into a creature of the human mind, and all human knowledge into an empirical self-knowledge. He gave a religious character to his theory, and exhibited in one respect an affinity with Malebranche, by affirming that the Deity originates our perceptions, which are the data to lead us to Him. The negative tendency of English philosophy culminated in Hume. He agreed with Bacon that all our knowledge is experimental; with Locke, that all experience is sensational; and with Berkeley, that sensuous perceptions imply no objective reality. The relation between objects is as unreal as the objects themselves, since the idea of causality is founded on a belief that a certain antecedent has a certain consequent, this belief on a feeling, this feeling on a habit, which is itself nothing but an oft-repeated experience. Thus even within the region of phenomena to which knowledge is limited, there is no perfect certainty, but only habit or probability. Experience, which Bacon had presupposed and accepted as the instrument of philosophy, is thus brought into the foreground as its problematic object. The effort to explain it introduced a new epoch in speculation, when philosophy passed from dogmatism to criticism, and sought in the transcendental or pure faculties of the human mind the powers which constitute the essence of humanity, and which precede and legitimate experience.—The philosophy of Descartes begins with methodical doubt, to which only one thing remained *certain*, viz., the certainty of thought. No one before him had so distinctly separated the human consciousness from matter, making them independent of and foreign to each other. He rendered the service of conquering nature, so that it remained a problem of thought, but was no longer a power in the mind. The basis of his system is the dualism and antagonism of spirit and matter, of subject and object. The *Cogito, ergo sum* forms a subjective dogmatic circle, around which lies the objective realm of phenomena. These two finite substances constitute the actual world. They are opposed, and mutually exclude each other, and no direct union of them is possible. Yet man is the synthesis of the two, and knowledge is the penetration of thought into nature. Only as the spiritual and natural combine can human life be conceived of. To explain the problem at once of this antagonism and this union, Descartes introduces the absolute substance or God as the copula between spirit and matter. Our idea of an infinite substance, a perfect being, could not be derived from finite thought; it therefore implies and represents an external existence; it is a divine datum in us, an innate idea, a mark left by God upon his work, like the monogram of an artist upon his production. With this idea the mind ceases to be certain of itself exclusively, and gains the possibility and principle of objective knowledge. The monologue of subjectivity terminates when the sun of the infinite rises on our thought and illumines the universe. By the consideration of the divine attributes we determine the truth of outward things. The test of certainty concerning objects is that our ideas of them be clear and distinct, because such ideas are innate, implanted by God. Nothing is true in nature which may not be distinctly grasped by thought. The theories developed by Descartes in physics have been overthrown by the progress of science. His metaphysical system was ineffectively opposed by the Epicureanism of Gassendi, and was modified by Geulincx and Malebranche. Both the latter admitted the antagonism of the two substances, and the impossibility of their union. Yet it is an indisputable though inexplicable fact that they are determined by each other, that the will moves the body and sensation affects the mind. This fact is, according to Geulincx, the miraculous work of God, who employs the will and the object of sensation as occasions of his own agency. The Deity is the actual cause of all mental and physical phenomena. His theory therefore bears the name of occasionalism. Malebranche also conceived that the antagonism is overcome only in God, but omitting the notion of miracle he tended to blend the infinite and the finite spirit, and regarded all human knowledge as a divine act. We see all things only in the Deity. The three substances which had formed eccentric spheres in the Cartesian system became concentric in that of Malebranche. A more important successor of Descartes was Spinoza. He remarked that in Cartesianism the absolute substance always remained in the background, and had been introduced as a theological resource, a *deus ex machina*, to solve a difficulty that presented itself in philosophy. The two finite substances were the actual heroes in the drama of the world. The scheme of Spinoza reduces the three Cartesian substances to unity, to one infinite original substance, the ground of all things, that excludes from itself all negation or determination, and is named God or nature. To this belong an infinite number of attributes, of which two only are known to us, thought and extension. Modes are the changing forms of these attributes. To regard finite things as distinct individualities is the mistake of our imagination; the reason contemplates them only as the *natura naturata* in which the *natura naturans* is revealed. This scheme is ontological, developed from *a priori* axioms, and is the most elaborate of all systems of pantheism. While Spinoza escaped from the dualism of Descartes by affirming that there is but one substance, of which all things are modes, Leibnitz increased to infinitude the number of substances. The universe is an aggregate of intelligent, self-active, immaterial points, which he calls monads, and which combine as elements to form every thing. They are unlike each other, but each follows the law of its own being, and cannot be affected by any thing external to itself. The soul therefore cannot work upon the body, and the relation between them is due to a preëstablished harmony, God having so constituted them in the beginning that they operate in perfect concord though independently. Our mental ideas proceed *pari passu* with external realities, though they have no connection with each other. God is the *monas monadum*, the sufficient cause of the universe, which is the best one of an infinitude of possible worlds that were contemplated by the divine intelligence. The theories of Leibnitz were systematized by Wolf, and from his time to Kant German philosophy assumed no new standpoint. In psychology Leibnitz prepared for Kant by seeking the distinction between necessary and contingent truths, maintaining that, though no ideas are innate, the mind by its own energies, apart from experience, generates necessary truths according to innate principles. The speculations of Jonathan Edwards, the greatest metaphysician of America, chiefly on the theological and ethical bearings of philosophy, belong to the school of Descartes and Leibnitz.—Meantime the empirical tendency of Bacon and Locke was developed in France and opposed in Scotland. Condillac reduced Locke's two sources of knowledge to one, regarded all ideas as transformed sensations, and made metaphysics, as Destutt de Tracy admits, a branch of zoology. His system triumphed over Cartesianism not so much by favoring observation of facts instead of deduction from ideas as by linking itself with social and ecclesiastical reforms, occupying itself with natural and public law, and encouraging abstract justice and right in political organizations. Helvetius, the moralist of sensationalism, esteemed self-love the only motive of human action. The tendency culminated in the reckless materialism and atheism of La Mettrie and D'Holbach, who deemed every thing spiritual an illusion and physical pleasure the only worthy object. In Scotland Reid undertook the refutation of Berkeley and Hume, by denying the hypothesis of representative ideas and affirming the authority of common sense. His negation at least called attention to abuses of language, and overthrew any meaning of idea in the sense of an intermediate image between the object and the mind in the act of perception. His affirmation has remained with modifications the peculiarity of the Scotch school. By common sense he means a kind of intellectual instinct. We believe by the very constitution of the mind in connection with every sensation in the existence of some external object as immediately and certainly as in our own existence. The sensation implies the object, and we require no proof to justify the testimony of our faculties. He applied the Baconian method to the mind, and by his analysis of the phenomena of perception gave a new prominence to psychology in metaphysical researches. In connection with empirical truths he maintained the existence of necessary and spontaneous judgments, laws of mind, instinctive principles, *a priori* intuitions, truths of common sense, which are not derived from experience, and which are the data of speculative philosophy. A more complete analysis of these fundamental laws or constituent elements of human reason was made by Dugald Stewart, who illustrated the system with peculiar beauty of style; but neither he nor his successor Dr. Brown removed the characteristic difficulty of the school to determine what mental phenomena are native and *a priori* and what adventitious and contingent. The Scotch philosophy was reproduced in America, with some modifications, by Prof. Upham.—Thus modern philosophy had culminated in the formal rationalism of Wolf in Germany, the materialism and scepticism of Condillac and Hume in England and France, and the protest in the name of ill-defined principles of common sense in Scotland. Kant now discovered the critical point of view, and took the same position with reference to experience and knowledge that had been taken by Bacon with reference to nature. Analyzing the phenomena of experience, he sought the powers or faculties which constitute it, the conditions which as necessary functions precede it, and which he called transcendental. He did not, like the followers of Descartes, presuppose knowledge in innate ideas, nor like the sensationalists presuppose experience in mental impressions, but aimed after the knowledge-forming faculties which precede all knowledge, and which make physics, mathematics, and metaphysics possible. The results of his critical examination were: that our intellectual nature is the product of 3 factors, sense, understanding, and reason; that all the material of our knowledge is furnished through sense in a formless mass; that the understanding reduces this material to shape and distinctness, to the unity of a notion, in accordance with its 12 categories, the matter of experience thus filling the form of conception; and that the reason, which rises above finite notions, and has no reference to objects, finds the unconditioned principles, the pure ideas, for the conditioned knowledge of the understanding. Now, as the objective world is known to us only in the form into which it is transmuted by the categories of the understanding, as our knowledge of things is thus purely subjective, as even the ideas of the reason are only our own modes of thinking, therefore ontology is scientifically impossible. Kant saves himself from pure subjective idealism only by retreat to his practical philosophy. Consciousness reveals to us the autonomy of the will, expressing itself in the supremacy of conscience, which is the categorical imperative. This moral nature implies freedom as its necessary condition; the existence of a God, as otherwise there would be a law without a law-giver or judge; and the immortality of the soul, for the completion of our moral existence. The practical reason affirms the reality of these things, not as theoretical dogmas, but as the necessary postulates and premises of our moral constitution and action. They lie beyond the bounds of actual science, but are the undemonstrable certainties of a rational faith. The ablest opponent of the Kantian philosophy, Jacobi, took the standpoint of faith in opposition to that of criticism in order to give theoretic certainty to the postulates of the practical reason. The absolute, which is unattainable by the reason, may be grasped by feeling, the *salto mortale* of the mind, which gives immediate knowledge requiring no other evidence. In his later writings he identified faith or intuition with the Kantian reason, claiming for the latter the faculty of objective knowledge. Fichte, the direct successor of Kant, introduced the philosophy of the absolute, proposing a single principle in opposition to the Kantian dualism of mind and the postulated objective world. All that is immediately true to us is our sensations, perceptions, and ideas, the phenomena of consciousness; and he therefore made *self* or the Ego the absolute principle, which by its own development becomes the universe, nature, and man, and appears as a spectacle unto itself. The individual consciousness is the manifestation of this absolute Ego, the phenomenal shadow of an ultimate reality, which is our essential self. The world also is but the sensized material of our practical life, the means by which we place before us, as object, the aim and end of our existence. Nothing exists but a certain subjective activity, of which the universe is the apparent reflex, and God the ideal or law. Thus Fichte consummated the subjective idealistic tendency. "We know nothing," says he, "but by consciousness; consciousness is but a phenomenon; the images present to us are formed of images and by images; all reality is changed into a wondrous dream, without a life to dream of and without a mind to dream, a dream composed of a dream of itself. Perception is a dream; thought is the dream of that dream." The speculative result is thus nihilism, but by his practical philosophy he postulated on the authority of faith the existence of God as the moral order of the world, and defined duty as the fulfilment of individual destiny, and destiny as the realization by humanity of the absolute Ego, of the ideal standard of reason. In his later system he approached the principle of identity, regarding the world and consciousness as both alike the image and impress of the divine life. This principle was fully developed by Schelling, who proposed an infinite, self-existent, self-unfolding mind, from which every thing else is developed, as the only absolute reality, forming of itself the real essence of the universe. Spirit and matter are in it identical. According to Fichte, the object is created by the subject; according to Schelling, both object and subject are emanations of the absolute, which works by a blind impulse in nature, comes to self-consciousness in mind, and is evolved by the necessary law or rhythm of its being through the whole material and mental universe. Every mind is a reflection and exemplar of the infinite mind; and therefore by gazing inwardly on our own mental processes we may learn the principle or process of the divine development. The organ of philosophy is an ecstatic intellectual intuition, superior to the laws of consciousness, which immediately knows the absolute, and to which subject and object are indifferent. By this intuition the mind becomes absolute and identical with the Deity; the process of thinking is therefore the same as that of creating; thought and being are one; and our logical deductions are the formulas of development in all the forms and regions of creation. The world is thus autonomic, presenting only individualizations of a common principle. The subjective idealism of Fichte, and the objective idealism of Schelling, were succeeded by the absolute idealism of Hegel. The absolute idea, logically and by its inherent energy developing itself through the forms of creation, and completing the circle of its activity in the rational self-consciousness of man, is the fundamental conception of Hegelianism. Logic is the basis of the system, the law of ideal evolution, the *a priori* science of the universe, the very substance of being. The world is visible logic. His absolute is neither the universal substance of Spinoza, nor the transcendental self of Fichte, nor the universal mind of Schelling, but it is the dialectical process or law of development. Nature is the idea externalizing itself, the transformation of abstractions into realities, and its aim is to raise itself to self-consciousness. "It is a dumb intelligence striving to articulate." Spirit is the idea having emancipated itself from nature, and waked to consciousness in man; and it is by this awaking that the universe, as such, is produced, since thought and existence are identical. The perfection of spirit is in revealed religion or absolute philosophy, in which the conscious idea attains to universality, and reproduces from itself the whole natural and intellectual universe. The atomic metaphysics of Herbart, the mysticism of Baader, the scheme of Trendelenburg, founded on the idea of individualism and personal destiny, and the pantheism of Kuno Fischer, are the more important of the minor German systems. The transcendental philosophy, unable to attain to the absolute through the consciousness, was obliged in each of its forms to assume the existence of a principle superior to consciousness. Some strict psychologists have therefore charged it with resting upon and describing purely imaginary and impossible mental operations. Its earlier results were made known and discussed in England by Coleridge and in America by James Marsh.—The reaction against sensationalism in France, which under the name of ideology reached its last results in the physiological psychology of Cabanis, the ethics of Volney, and the logical deductions of Destutt de Tracy, began with the admission by Laromiguière of an active as well as passive element in the mind in perception, with the adoption of the Scotch philosophy by Royer-Collard, and with the stress laid on the power of the will by Maine de Biran. Cousin succeeded with the system of eclecticism. The results of all philosophical research, according to him, had been either sensationalism, idealism, scepticism, or mysticism, each of which contains a truth in excess. The eclectic method proposed to disengage the truth from each of them, and to combine these elements in a system which should be a harmonious expression of complete truth. The capital questions had been profoundly and repeatedly explored; all that remained to be done was to conciliate the results. The criterion of truth is the impersonal and divine reason, in which all rational beings share, and which is the source and test of absolute ideas. Jouffroy and Damiron were the principal followers of Cousin. Meantime an ecclesiastical and traditional tendency in philosophy was illustrated by De Maistre, Lamennais, and Bonald, whose aim was to substitute faith for knowledge and authority for investigation. Man as an individual, according to Lamennais, has no criterion of truth; but the universal beliefs of the whole race, the authoritative traditions of all time, are to be accepted as a divine revelation. He sought, therefore, to prove that the Christian religion, either in its purity or in offshoots and counterfeits, had been universally recognized by the faith of mankind, and constitutes the only attainable system of truth. His later writings contain an ontological system akin to Neo-Platonism. Another tendency appeared in the socialistic mystics St. Simon, Fourier, and Pierre Leroux. St. Simon aimed to extinguish individualism in social order, and maintained that true philosophy should be sought historically, that it existed in minds rather than in mind. From history and not psychology he derived his law of development, which was to be at once a system of religion, philosophy, and government. Fourier excelled in the analysis of the passions, which alone, according to him, constitute the real man, and inferred that the Newtonian principle of attraction was applicable to them, and might be made to harmonize social life. By the principle of universal analogy he proposed theosophic doctrines of cosmogony and destiny beyond the possible scope of induction. Leroux regarded individual man as a mere abstraction, the whole of humanity as the only real existence, tradition as the source and organic social life as the object of philosophy.—A peculiar philosophical school has flourished in Italy during the present century, the representatives of which are Rosmini, Mamiani, and Gioberti. According to Rosmini, the starting point of all philosophical investigation, the apodictical element of all thought, the primitive and necessary intuition, is the idea of possible being. This idea, the first psychological fact, being associated with a perception of sense, the first ontological fact, loses its indeterminate character, and is transformed into knowledge. The former belongs to the domain of philosophy, the latter to that of physiology. The notion of time is the synthesis of the idea of possible being with that of the contingent duration of phenomena, and the notions of space, cause, and substance are similarly formed. Instead of seeking, like modern psychologists, his point of departure in the individual consciousness, he introduces an *a priori* element, a hypothesis anterior to all mental experience, as the abstract condition and foundation of thought, which has only to be developed and applied in connection with sensation to constitute all intellectual acts and a system of the universe. The aim of Mamiani was to demonstrate a dogmatic philosophy, to prove the objective reality of ideas. Combining the *a priori* and the empirical methods, he made the criterion of truth an immediate intuition, which involves the assent of all the faculties. His principal merit is in the methodical arrangement of principles borrowed from all schools, and in directing attention to the natural laws which govern the applications of human thought. His character as a philosopher appears in his aspiration for the time "when, in the heart and mind, instinct, religion, and science shall become one and the same thing, when instinct shall be rational, philosophy profoundly religious, and religion perfect wisdom." Gioberti and Rosmini have been characterized as the Plato and Aristotle of modern Italy. The former developed what has been called a "philosophy militant," designed to reconstruct all modern science and society. Psychology he pronounces the essence of philosophical and religious heterodoxy, and the attempt to develop the universal from the contingent totally fruitless. He proclaims the intuition, not like Rosmini of possible being, but of real being, of the active Deity, as the absolute source of existence, and proposes the formula *L'ente crea esistenze* as the supreme formula by which every thing is explained. Real existence in the act of creation is the goal of thought alike in metaphysics, physics, ethics, æsthetics, and politics. Philosophy is founded on revelation and perpetuated by the church, which is the depositary of truth, and which creates civilization. The Italian school is remarkable for its *a priori* method and its respect for ecclesiastical and national tradition.—More influential at the present time than any other system since that of Hegel are the philosophy of the conditioned of Sir William Hamilton and the positive science of Auguste Comte. The former adheres to the traditions of the Scotch school by affirming that our consciousness in the act of perception makes us immediately cognizant of something external and extended. Our knowledge is conditioned by our faculties: we have no faculty for comprehending the infinite and absolute; and all human philosophy, therefore, treats only of the relative and phenomenal. The whole matter of the absolute is declared to be *nihil cogitabile*, and is transferred from the province of philosophy to that of religion, from reason to faith. We can know only finite phenomena, but faith assures us of the unconditioned, though we cannot conceive it. That our faculties are inadequate, that several of the fundamental laws of thought are results of the imbecility of the mind and not positive affirmations of intelligence, is demonstrable; but faith forbids us to admit that the mind, though weak, is false. The positivism of Comte develops the negative, and denies the positive side of this composite system of science and faith. It affirms that we can know nothing but phenomena, their resemblances, coexistences, and successions; that psychology, the pretended self-contemplation of the mind, is an utter illusion, and objective facts alone can be observed; that the endeavor to penetrate into ontology is hopeless, the knowledge of essences and causes being beyond our possible scope. There are three eras of human development. In the first, theological hypotheses were proposed to explain phenomena; in the second, metaphysical hypotheses; but in the third the futility of both is perceived, and mankind, ceasing to make ontological inquiries, accepts all facts as mere phenomena, and classifies them by the relations of succession and similitude which they bear to each other. The perfection of positive science would be a complete view of all phenomena in their relations. This system is represented with modifications, in England, by John Stuart Mill, G. H. Lewes, and Herbert Spencer.—The principal general histories of philosophy are: Brucker, *Historia Critica Philosophiæ* (5 vols., Leipsic, 1742–'4); Tiedemann, *Geist der speculativen Philosophie* (6 vols., Marburg, 1791–'7); Tennemann, *Geschichte der Philosophie* (11 vols., Leipsic, 1798–1819; an English translation of an abridged edition was made by Arthur Johnson, Oxford, 1832, and revised by J. D. Morell, London, 1852); Windischmann, *Die Philosophie im Fortgang der Weltgeschichte* (4 vols., Bonn, 1827–'32); Hegel, *Geschichte der Philosophie* (3 vols., Berlin, 1833–'6); Ritter, *Geschichte der Philosophie* (12 vols., Hamburg, 1836–'53; partly translated by Morrison, 4 vols., London, 1838); Schwegler, *Geschichte der Philosophie* (Stuttgart, 1848; translated by Seelye, New York, 1856); De Gérando, *Histoire comparée des systèmes de philosophie* (2d ed., 4 vols., Paris, 1822–'3); Cousin, *Cours de philosophie morale* (1840–'41); Enfield, "History of Philosophy" (2 vols., London, 1791); and Lewes, "Biographical History of Philosophy" (London and New York, 1857). The best special history of occidental philosophy is by Röth, *Geschichte unserer abendländischen Philosophie* (2 vols., Mannheim, 1846–'58). The principal special accounts of ancient philosophy are: Zeller, *Die Philosophie der Griechen* (Tübingen, 1844); Matter, *Histoire de l'école d'Alexandrie* (Paris, 1840); Jules Simon, *Histoire de l'école d'Alexandrie* (2 vols., Paris, 1845); Vacherot, *Histoire critique de l'école d'Alexandrie* (3 vols., Paris, 1846–'51); and W. A. Butler, "Lectures on the History of Ancient Philosophy," edited by Thompson (2 vols., Cambridge, 1856). Special works on the scholastic philosophy are: Rousselot, *Études sur la philosophie dans le moyen âge* (3 vols., Paris, 1840–'42); Caraman, *Histoire des révolutions de la philosophie en France* (3 vols., Paris, 1847); and Hauréau, *Histoire de la philosophie scolastique* (2 vols., Paris, 1850). The principal histories of modern philosophy are: Kuno Fischer, *Geschichte der neuern Philosophie* (5 vols., Mannheim, 1854–'70); K. L. Michelet, *Geschichte der letzten Systeme der Philosophie in Deutschland* (2 vols., Berlin, 1837–'8); Chalybäus, *Entwickelungsgeschichte der Philosophie* (translated into English, Edinburgh, 1854); Rémusat, *De la philosophie Allemande* (Paris, 1846); Willm, *Histoire de la philosophie Allemande depuis Kant jusqu'à Hegel* (4 vols., Paris, 1846–'9); Debrit, *Histoire des doctrines philosophiques dans l'Italie contemporaine* (Paris, 1859); Taine, *Les philosophes Français au XIXe siècle* (Paris, 1860); and Morell, "An Historical and Critical View of the Speculative Philosophy of Europe in the 19th Century" (2d ed., 2 vols., London, 1857; republished in New York). The most valuable cyclopædias of philosophy are: Krug, *Encyclopädisch-philosophisches Lexikon* (5 vols., Leipsic, 1827–'9); and Franck, *Dictionnaire des sciences philosophiques* (6 vols., Paris, 1844–'52). The principal periodical devoted entirely to metaphysics is the *Zeitschrift für Philosophie und speculative Theologie*, which has been published in Germany since 1837.

PHILOSOPHY, MORAL. See MORAL PHILOSOPHY.

PHIPPS, CONSTANTINE JOHN. See MULGRAVE, BARON.

PHIPS, or PHIPPS, SIR WILLIAM, governor of Massachusetts, born in Woolwich, Maine, Feb. 2, 1651, died in London, Feb. 18, 1695. He was one of 26 children, was at first employed as a shepherd, and at the age of 18 bound himself to a ship carpenter, and subsequently went into business on his own account, although his early education had been so neglected that he was unable to read or write. These defects, however, he soon repaired to some extent. A few years after coming of age, he went to England in order to procure means for an expedition to recover a Spanish vessel, loaded with treasures, which had been wrecked near the Bahamas. With a national vessel furnished him by the admiralty he made the expedition, but did not succeed in his search; but a second attempt, in which the means were supplied by the duke of Albemarle, was crowned with success. He recovered from the wreck treasure to the amount of £300,000, of which £16,000 was given him as his share, and in addition he received the honor of knighthood, and was appointed high sheriff of New England. In this capacity he returned to his native country, and remained for some time in Boston; but disagreeing with some other officers, he went back to England. In 1690 he commanded the fleet which captured Port Royal, and in the same year a much larger one sent against Quebec, which failed of success. He arrived in Boston in November, and was made a magistrate of the colony, but soon departed to England in order to induce the government to send another expedition to Canada. At this time the agents of Massachusetts were endeavoring to obtain from King William the restoration of the old charter; but not succeeding in this, a new one called the province charter was granted them in 1692. Phips was a member of the North church of Boston, of which Cotton Mather was pastor, and was noted for his zeal for Puritanism; and out of deference to the wishes of Increase Mather, the agent of Massachusetts in England, he was appointed captain-general and governor-in-chief of the province, and arrived in Boston May 14, 1692. In 1694 he was summoned to England to answer complaints which had been brought against him; but while there, and when it seemed that the difficulties would be settled in his favor, he suddenly died. He was a lover of his country, and aimed to discharge the duties of his office justly; but the violence of his temper led him constantly to commit acts which weakened his influence. He was, says Bancroft, "of a dull intellect, headstrong, and with a reason so feeble, that in politics he knew nothing of general principles, in religion was the victim to superstition." He is strongly eulogized by Cotton Mather, with whom he coöperated in the witchcraft delusion. (See "Life of Sir William Phips," by Francis Bowen, in Sparks's "American Biography," vol. vii.)

PHLEBITIS (Gr. φλεψ, φλεβος, a vein), inflammation of the veins. Phlebitis is one of the numerous diseases which modern observation has added to the domain of medicine. First noticed by John Hunter in 1784, numerous isolated cases were soon after published, and in the early part of the 19th century the disease was fully illustrated by the labors of the French pathologists. Phlebitis is of two kinds, adhesive and suppurative. Adhesive phlebitis is a local disease, occasioned generally by some mechanical injury done to the coats of a vein, or by some source of local irritation in its neighborhood. It is marked by a dull pain in the part, by swelling, hardness, and tenderness of the affected vein, and, when this is a main venous trunk, by œdema of the parts whose blood is returned by it; phlegmasia dolens is thus properly a phlebitis. The effect of adhesive phlebitis is to determine the formation of fibrinous clots which adhere more or less strongly to the walls of the vein, blocking up its caliber. After a time the adhesions become loosened, the clots are absorbed, and the circulation through the vein is restored. The disease, except where the blocking up of a main trunk may cause embarrassment to the circulation, is not a serious one; rest and perhaps the application of a few leeches along the course of the affected vein are all that is necessary for its cure.—In suppurative phlebitis the local symptoms are often so little marked as to attract no attention, while the general symptoms are of the gravest character. The latter ordinarily commence by a marked chill, and this is repeated at irregular intervals, in some cases several times a day, throughout the disease. The chills are followed by heat of skin and great frequency of pulse, and these terminate generally in a profuse sweat. The vital powers are commonly early depressed, and the patient complains of great weakness. The appetite is totally lost, the tongue is red and dry, sometimes sordes of the teeth and mouth are present, and sometimes there is copious and offensive diarrhœa. In the course of the disease abscesses may make their appearance at different points in the subcutaneous cellular tissue, or one or more of the joints may become distended with pus. On examination after death pus is often found in the veins, with numerous (multiple) abscesses in the parenchyma of the lungs or liver. The disease is almost necessarily fatal. and medicine can do little to retard its progress; to support the system of the patient by appropriate food, by quinine and stimulants, seems the principal indication.

PHLEBOTOMY. See Bloodletting.

PHLEGMASIA DOLENS, or Phlegmasia Alba Dolens, an œdematous swelling of one or both of the lower extremities, commonly called milk leg, attended with pain, and occurring soon after childbirth. The disease was first noticed at the commencement of the 17th century. It was for a long time attributed to deposits of milk in the affected leg, and afterward to obstruction of the lymphatics, &c. In 1823 Dr. Davis of London and Dr. Bouilland of Paris both published post-mortem examinations of cases of phlegmasia dolens, in which the femoral vein in the affected extremity was found inflamed and obstructed by fibrinous deposits. A few years later Dr. Robert Lee traced the inflammation from the femoral to the uterine veins. It would seem, then, well established that the disease is simply an adhesive phlebitis, having its origin generally in the uterine veins. The attack comes on commonly within 2 or 3 weeks after delivery, with pain in the lower part of the pelvis, extending rapidly below Poupart's ligament in the course of the femoral vein, or perhaps commencing in the calf of the leg. The pain, which is commonly attributed to rheumatism, is soon followed by swelling. This may be moderate in amount and confined to the leg, or it may be enormous and involve the whole extremity. When the swelling is great, the limb is white, hard, hot, and does not pit on pressure. The inflamed vein can be commonly traced below the groin as a hard, painful cord. There is fever, loss of appetite, and sleeplessness. The disease is ordinarily without danger, the swelling gradually subsiding after a time, though more or less œdema is sometimes permanently left. Rest, the application of a few leeches along the course of the inflamed vein, and an unirritating diet are all that is necessary for the cure of the disease.

PHLIASIA, a division of the Peloponnesus, bounded N. by Sicyonia, E. by Cleonæ, S. by Argolis, and W. by Arcadia. It consists of a small valley, 900 feet above the sea level, and is enclosed by mountains. The river Asopus flows through the middle of the plain. In antiquity this territory was renowned for its wine. The only place of importance was the city of Phlius, which was a Doric state, and usually governed by an aristocracy, although once subject to the tyrant Leon, a contemporary of Pythagoras. It sent 200 soldiers to Thermopplæ and 1,000 to Platæa, and during the Peloponnesian war was the faithful ally of Sparta. Afterward a division arose in the city, and the friends of the Lacedæmonians were banished; but in 393 B. C. the Phliasians received from Iphicrates so severe a defeat that they were forced to admit a Lacedæmonian garrison for their defence, which however did not restore the exiles. In 380 and 379 it sustained from Agesilaus, at the head of a Spartan army, a siege of one year and 6 months. Having surrendered, it remained faithful to Sparta during the Theban war, was governed by tyrants after the death of Alexander, and subsequently joined the Achæan league. Phlius was the birthplace of Pratinas, the inventor of the satyric drama. In the present kingdom of Greece Phliasia forms part of the nomarchy of Achaia and Elis.

PHLOGISTON. See CHEMISTRY, vol. v. p. 24.

PHOCION, an Athenian general, born about 402 B. C., put to death in 317. The son of a pestle maker, he studied under Plato and Xenocrates, and first distinguished himself in the naval victory gained at Naxos in 376 by the Athenians under Chabrias over the Lacedæmonians, but for many years after was not prominent in public life. Sent into Eubœa about 350 at the head of a small force to assist Plutarch, tyrant of Eretria, he was betrayed by the latter, and for a time was exposed to imminent danger; but he finally gained a complete victory at Tamynæ over the party of Philip. In 340 he was despatched with a fleet to the relief of Byzantium, then closely besieged by the Macedonians, and was enabled to force Philip to retire from the Chersonesus. Although so successful in war, Phocion was always an advocate of the temporizing policy of the peace party, and thus stood in direct opposition to Demosthenes. When Thebes, on the reported death of Alexander, declared itself independent of Macedon, the Athenians were prevented by his influence from giving them assistance, and occupying the pass of Thermopylæ. A little later he advised compliance with the demand of Alexander that the 10 leaders of the anti-Macedonian party should be given up, which proposition was indignantly rejected; but he nevertheless headed the second embassy, by the agency of which the demand was waived. After the death of Alexander, Phocion attempted to discourage the effort of the Greeks to free themselves from the Macedonian yoke. When the effort proved unsuccessful, he was one of the envoys sent to Antipater, and only succeeded in concluding a treaty on the hard conditions that the Athenians should pay a sum equal to the whole cost of the war, should surrender the anti-Macedonian orators, should receive a Macedonian garrison at Munychia, and should abandon their democratic constitution, and disfranchise their poorer citizens. He was now at the head of the Macedonian party in Athens, and while in that position was suspected of complicity with Nicanor, the general of Cassander, commander of the Macedonian garrison, and subsequently with Alexander, son of Polysperchon, who was besieging Nicanor. On the return of the Athenian exiles, and the restoration of the democratic government, he was compelled to flee to Polysperchon in Phocis, by whom he was sent back to Athens for trial. With 4 others he was condemned to drink the hemlock. He charged his son not to hold evil memory of the Athenians, and it is said was called upon to pay for his own execution, inasmuch as the poison having been exhausted the gaoler refused to procure any more without compensation; whereupon Phocion, borrowing 12 drachmæ, remarked that it was very hard a man could not even die gratis at Athens. Shortly after Cassander obtained possession of the city, the oligarchical party regained power, and celebrated Phocion's funeral obsequies at the public expense, erected a statue in his honor, and punished his accusers. Phocion was a man of great courage, a good general, and above all free from the least suspicion of personal corruption. By his reputation among the Athenians for this last quality he acquired in great measure his influence with the people, so that he was elected the unparalleled number of 45 times to the office of general of the city, without having solicited the position or having been present at the choice. Although not a professed orator, his brief and powerful speeches and his sarcastic manner exerted so great an influence, that Demosthenes, on seeing him rise, once said: "Here comes the cleaver of my harangues." In outward manner he was severe and surly, although said to be kind-hearted. He had a contempt for the people which he never affected to hide; and once, when tumultuously applauded in a public assembly, he turned round to a friend and inquired: "What folly have I uttered, that these men applaud me?" His probity was never shaken by the tempting offers of money and favor held out by Philip, and afterward by Alexander, who entertained for him a high regard. But he did gratuitously for the Macedonians what others did for pay, and lent the influence of his undoubted patriotism to that temporizing policy which ultimately involved Athens and the other Grecian states in a common ruin.

PHOCIS, a country of central Greece, bounded N. by the Locri Epicnemidii and the Locri Opuntii, E. by Bœotia, S. by the Corinthian gulf, and W. by Doris and the Locri Ozolæ. At one time it also comprehended a port on the Eubœan sea, called Daphnus. The principal city of Phocis was Delphi. The next in importance was Elatea, on the left bank of the Cephissus, commanding the road leading from the north of Greece to Bœotia and Attica. Beside these, there were several other cities of importance, such as Cirrha, the port of Delphi; Anticyra or Anticirrha, renowned for its preparations of hellebore; and Abæ, distinguished for its ancient oracle of Apollo. The largest river is the Cephissus, which flows through the northern portion of the country, and falls into Lake Copais in Bœotia. The country is exceedingly mountainous. The Parnassus range extends over the greater portion of it, the southern branch of the chain called Cirphis touching the Corinthian gulf between Cirrha and Anticyra. Below this range are several fertile valleys, of which the largest was the celebrated Crissæan plain. Between Parnassus and the Locrian mountains on the N. is the valley of the Cephissus, which embraces a few fertile though narrow plains. The chief importance of Phocis is due to the fact that the oracle of Delphi was within its boundaries. The Phocians proper, who inhabited both banks of the Cephissus, formed a confederation, which assembled at Daulis in a building called Phocicum. This confederation maintained its freedom, although frequently attacked by the Thessalians; and the latter, at the time of the invasion of Xerxes, led the Persian troops into Phocis, and destroyed 12 cities. Originally the temple of Delphi had been in their power, but they were early deprived of it by the Delphians, who held it till 450 B. C. It now came again into the hands of the Phocians, and both Lacedæmonian and Athenian forces marched into their territory, the one to attack, and the latter to defend. They held possession of the temple until the peace of Nicias (421), having been during the Peloponnesian war firm allies of the Athenians. But by the terms of that peace, the Delphians resumed their sovereignty over the temple, which remained in their hands until the sacred war. After the battle of Leuctra in 371, the Phocians came under the dominion of the Thebans, and remained in that condition until the death of Epaminondas, when they asserted their independence. For this the Thebans persuaded the amphictyons to enforce an old edict ordering the Phocians to pay a fine for having occupied a tract of land near Cirrha belonging to the temple of Apollo at Delphi. Their refusal gave rise to the sacred war, which lasted from 355 to 346 B. C., in which the Phocians maintained themselves by despoiling the temple, and were only reduced by the strategy of Philip of Macedon. A decree was hereupon issued by the amphictyons that the towns of Phocis, numbering 22, should be destroyed with the exception of Abæ, that the inhabitants should be scattered into villages, that no village should contain more than 50 dwellings, and that the inhabitants should repay to the temple the treasure they had taken, contributing each year 50 talents. The operations of the war which Philip afterward carried on against the Thebans and Athenians were principally in Phocis, and its people fought at the battle of Chæronea on the side of Greek independence. Phocis and Phthiotis together now form a nomarchy of the kingdom of Greece, their population amounting in 1856 to 91,944, and their capital being Lamia.

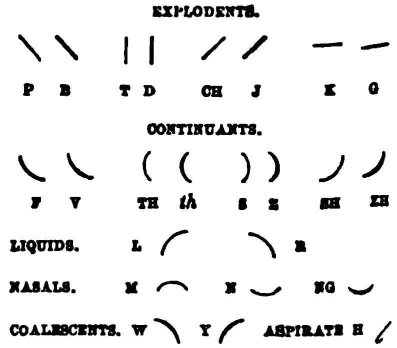
PHŒBUS. See Apollo.

PHŒNICIA (Gr. Φοινικη, from φοινιξ, a palm tree), the name given by the Greek and Roman writers to the narrow region which lies between the hills of Palestine and the mountains of Syria on the E. and the Mediterranean on the W. By the Phœnicians themselves their country was called Canaan. Its northern boundary in a political sense was near Aradus in lat. 34° 52′ N., and its southern near Joppa in lat. 32° 2′ N., and its length about 200 m. The breadth never in any part exceeded 12 m., and was generally much less. The total area therefore was less than 2,000 sq. m. From Aradus to Tripolis the coast forms a bay into which several rivers fall having a short course from the mountains. Tripolis, now called Tarablus, stands on a promontory ½ m. broad and extending a mile into the sea. A chain of 7 small islands running out to the N. W. protects its harbor from the prevalent winds. S. of Tripolis a low range of chalk hills borders so closely on the sea that there is no room for a road between them. Further S. they recede a little from the sea, and on a narrow strip stands Batroun, the ancient Botrys; and still further S., on a hill by the shore, stood the city called Byblus by the Greeks. A little S. of Byblus is the river Ibrim, the ancient Adonis, which was said to be annually changed into blood, and which still assumes in summer a red color derived perhaps from the ferruginous sands of the mountains from which it flows. A few miles further S. stood Berytus, now Beyroot, on the most projecting headland of the coast, with the mountain range of Lebanon in full sight across a plain of luxuriant fertility. Berytus, though not much celebrated in profane history, was one of the oldest of Phœnician towns. The plain in which it stood extends southward 10 m. to the mouth of the river Damour, the Tamyras of ancient geography, beyond which the hills again press closely on the sea for several miles. There, on the slope of a small promontory, is seen the site of Sidon, the oldest and one of the most famous of the cities of Phœnicia. The plain of Sidon is prolonged as far as Sarepta, the Zarephath of the Old Testament, 8 m. to the south. From Sarepta the plain again widens and continues as far as Tyre, with an average width of about 2 m.; near that city it widens to 5 m.; 8 m. S. of Tyre it terminates in the White promontory rising perpendicularly from the sea to the height of 300 feet. The road here, which in some places hangs over the water, was cut through the rock, it is said, by Alexander the Great. Originally it appears to have been ascended by steps, and was therefore called the Tyrian *climax*, or staircase. About 30 m. still further S. Acre or Acco, the Ptolemais of the Greeks, stands on the N. projection of a bay which is about 8 m. across and is terminated on the S. by the promontory of Carmel. A few miles southward is Dorce, anciently a town of considerable magnitude, next to which at no great distance the important city of Cæsarea was in later ages built by Herod the Great. At Jaffa, the ancient Joppa, 30 m. southward, the Phœnician territory terminated. The vicintry of the Nile affects the coast of Phœnicia even as far N. as Tyre and Sidon. The set of the currents carries regularly to the eastward the alluvial matter which the river pours into the sea, and deposits it on the coast, so that towns formerly maritime have become inland, and harbors which once received fleets of ships are now filled up. (For the climate and natural history of Phœnicia, see PALESTINE, and SYRIA.) —Though the Phœnicians appear to have dwelt on the sea coast of Syria at the earliest dawn of history, they always considered themselves as colonists and not as aborigines. Herodotus says they came from the Erythræan sea, that is, that part of the Indian ocean which washes the shores of Arabia and Persia, to the Mediterranean, "and having settled in the country which they now occupy, immediately undertook distant voyages; and, carrying cargoes both of Egyptian and Assyrian goods, visited, among other places, Argos." In the Scriptures they are always termed Canaanites, and are classed among the descendants of Ham. They were of darker complexion than the other Syrians, and the Greek writers frequently speak of them as Ethiopians. The most probable theory in regard to them is that ethnologically they were Arabs or connected with the Arabian family of mankind. Like the Arabs to this day on the shores of the Indian ocean, they were at once pirates and merchants. Kidnapping and barter were practised indifferently by the crews of their ships. Homer represents them as carrying off and selling for slaves those whom they could get into their power by force or fraud. But though Europe suffered from their piracy, it is certain that from their visits she received the rudiments of her civilization and imbibed a taste for the elegances of life. The use of alphabetical characters and also arithmetic has been clearly derived from Phœnicia by every ancient European nation. The choicest works of art known to the earlier Greeks came from Sidon; the produce of its looms furnished the costliest offering to the gods; and its trinkets adorned the persons of the Grecian women. They traded where trade was profitable, and concealed from others the course they pursued to reach the distant countries to which their traffic extended. Thus, though they had supplied tin and amber for several centuries to the Greeks, Herodotus, who had visited Tyre itself, could obtain only very vague accounts of the countries in which they were produced. The master of a Phœnician merchantman bound for the land which produced tin, perceiving himself followed by a Roman ship which had been sent to learn the way, ran his vessel on the rocks to lead the rival craft to destruction; and on his return home the government remunerated him for the loss he had patriotically incurred. The commerce of Phœnicia appears to have reached its height about the 8th century B. C. Ezekiel (chap. xxvii.) draws a vivid picture of the commercial splendor of Tyre at the end of the 7th century, at which period its trade directly or indirectly embraced the whole known world. By means of the Red sea and the Persian gulf it communicated with India and the E. coast of Africa; on the N. its vessels found their way along the Euxine to the frozen borders of Scythia; beyond the straits of Gibraltar its ships or those of its colonies visited the British isles for tin, and perhaps penetrated even into the Baltic in search of amber; and it is probable that they had several centuries before sailed along the Atlantic coast of Africa beyond the great desert, and had discovered the Canary islands. Beside carrying on commerce on a large scale in fleets and caravans, the Phœnicians appear to have traversed the interior of Syria and Palestine as peddlers, retailing the goods which they had imported or manufactured from house to house, and purchasing at the same time the domestic products of those countries. It was on the sea, however, that the Phœnicians were eminent above all other nations. For their shipping Lebanon afforded inexhaustible supplies of timber, and from Cyprus they obtained every thing else that was necessary for fitting out a vessel. Sidon among their cities appears to have enjoyed the highest reputation for naval skill. Of the form or tonnage or rigging of their vessels nothing is known, except that they were equipped for war as well as for trade, and their discipline was so good that even in Athens, the first maritime state of Greece, Xenophon cites a Phœnician ship as the best example of order and skilful arrangement that could anywhere be found. The Phœnicians were the first to apply astronomy practically to navigation, and they had noticed the connection of the moon with the tides, with which they had become acquainted in their Atlantic voyages.—Of their manufactures, the most famous was that of the purple dye, which they prepared from a shell fish found on the coast. Though a similar purple was produced at various places on the coasts of Greece, Italy, and Africa, Phœnicia, especially the city of Tyre, always maintained its preëminence in this particular. It had the advantage of an inexhaustible supply of the shell fish, a brilliant sunlight, and probably some knowledge of chemistry by which the native color of the liquor was heightened. As Tyre was celebrated for its purple, so Sidon was noted for its glass, the invention of which was attributed by the ancients to the Phœnicians. The Sidonians used the blowpipe, the lathe, and the graver, and cast mirrors of glass. They were also acquainted with the art of imitating precious stones and of coloring glass by means of metallic oxides. They excelled in the manufacture of drinking vessels of gold and silver. Hiram the Phœnician king sent to Solomon to aid in building the temple, an artist, "skilful to work in gold and in silver, in brass, in iron, in stone, and in timber, in purple, in blue, and in fine linen, and in crimson; also to grave any manner of graving." (2 Chron. ii. 13, 14.) The Phœnicians were celebrated also for the manufacture of perfumes. Their skill in mining and metallurgy was apparently greater than that of any other ancient nation, and their mining operations in Spain were carried on upon a stupendous scale and by very scientific methods. —A chief source of the power and wealth and extensive commerce of the Phœnicians was their system of colonization. The progress of their settlements naturally divides itself into three successive eras, during the first of which they colonized the shores of the eastern Mediterranean, including the Ægæan and the Euxine; during the second the central part of the coast of N. Africa; and during the third the remaining coasts of the Mediterranean westward into the Atlantic. Their settlements in the first and second of these areas have no definite chronology, and can only be traced through the clouds of mythic legends transmitted to us by the Greeks. It is probable, however, that they were expelled from the islands of the Ægæan by Minos three generations before the Trojan war, and we may infer that they then settled in Sicily. At an early period they occupied Cyprus, Crete, and Rhodes, where their presence is attested by a multitude of inscriptions. Cilicia, Lycia, Caria, and other parts of the coast of Asia Minor were colonized by them, and their settlements at Thebes and other places in Greece under Cadmus gave rise to some of the most noted legends of the Greeks. The next great step in the progress of Phœnician colonization seems to have been the settlement of promontories and islets on the coast of Sicily. Malta or Melita was one of their earliest possessions in this region. The island of Sardinia is mentioned by Diodorus as one of the places to which the Phœnicians sent colonies after they had enriched themselves by the silver of Spain. On the Spanish peninsula their first settlement was Gadira, the modern Cadiz, which they colonized about 1100 B. C., the first date in their history to which we are able to give a definite position. But the greatest and most successful of their colonies were those in N. Africa, where Ituke, by the Romans called Utica, was founded about the same time that Cadiz was settled. In the same vicinity more than two centuries later Carthage was founded by a colony from Tyre, although there is some reason to suppose a much earlier settlement of the site by a colony from Sidon. It is certain however that it was to the emigration from Tyre, about the end of the 9th century B. C., that Carthage owed its rapid rise to power and opulence. The history of these colonies is in most cases too obscure to allow of our defining the relation in which they stood to the mother country. Their connection was very slight, and was maintained rather by filial piety than by political dependence. The tutelary god of Tyre was also the chief god of Carthage, and the latter city annually sent offerings to the parent temple. When Cambyses threatened to make war on Carthage, the Phœnicians who served in his fleet refused to engage in hostilities against the Carthaginians because they regarded them as their children. On the other hand, the colonies aided the mother country with ships and soldiers in her wars, but they seem to have been entirely independent in all other respects.—From the earliest period of which we have any knowledge the cities of Phœnicia were governed each by a king. Such was the condition of Canaan when invaded by the Israelites. Every town with its adjacent territory constituted a sovereignty. The monarchy was hereditary wherever we can trace its descent, but the sanction of the people was necessary to the succession, and to them the right of election devolved in case of a vacancy of the throne. In Tyre, and probably also in Sidon and the other principal cities, a powerful aristocracy existed along with the monarchy, though we have no precise knowledge on what the distinction of nobility was founded. The chief nobles seem to have held to some extent the functions of a senate. At Tyre, when the throne was vacant, the place of the sovereign was supplied by elective magistrates called *soffets* or judges. A large part of the population of Phœnicia was composed of slaves, who were brought from all parts of the ancient world, and whose numbers were such in Tyre that on one occasion they rose in insurrection and expelled the free population. The cities of Phœnicia were never united under a single monarch, but generally the superior power of some city, at first Sidon and afterward Tyre, enabled it to exercise that controlling power over the others which the Greeks termed hegemony. The three principal cities, Sidon, Tyre, and Aradus, had a place of joint meeting, the town of Tripolis, where measures of the highest importance were decided by a representative assembly, of whose exact nature little is known. The chief defence of the Phœnicians was their naval power, and in later ages, when the rise of the great monarchies on the Tigris and Euphrates threatened their safety, their reliance was on mercenary troops whom their wealth easily procured, chiefly from Africa. The narrow extent and limited population of their own land made it impossible to raise native armies able to cope with the Assyrians and Babylonians, or later with the Persians and Macedonians.—Of the religion of Phœnicia we know nothing except from incidental notices in the Greek and Latin writers, and in the Hebrew Scriptures. From them we learn that polytheism prevailed among the people, and that the chief deities were Baal and Ashtoreth, who are supposed to represent the sun and moon; a deity whom the Greeks called Cronos (Saturn), but whose Phœnician title is not certainly known; Moloch or Melkarth, the especial god of Tyre. Saturn and Moloch were worshipped with bloody sacrifices, in which large numbers of infants were sometimes burned alive. When great dangers from war or other evils menaced the state, the supposed anger of the deities was thought to be averted by sacrificing on their altars the noblest and most beloved children. Our knowledge of the Phœnician religion, however, is derived almost wholly from their enemies, and is merely external. Of the spiritual or moral ideas of the people we know nothing. From the doubtful fragments of Sanchoniathon it may be inferred that their speculative philosophy was atheistic, and that they had no belief in a future life.—The principal Phœnician cities, Tyre and Sidon, were founded, according to the statement of Herodotus, about 2700 or 2800 B. C. For several succeeding centuries they pursued a profitable career of commercial activity. But it is not until the time of Solomon that we have any certain historical knowledge of their affairs. Hiram, king of Tyre, and his predecessor Abibal, are historical personages, and from them we have a regular succession of kings with dates of their reigns. The friendship and alliance of Hiram and Solomon, and the voyages of their fleets to Ophir, are recorded in Scripture. Of Hiram's successors the most noted was Pygmalion, whose tyranny about the end of the 9th century B. C. drove his sister Elissa or Dido into exile with a large body of followers, by whom Carthage was founded. Subsequently the oppression of Tyre produced a revolt in Cyprus, which was joined by Sidon and several other cities. The rebels were assisted by the Assyrians under Shalmaneser, who overran Phœnicia, but made no permanent conquest. He afterward made a second inroad, and besieged Tyre for 5 years without success. Subsequently Phœnicia became involved in war with the Babylonians, whose king Nebuchadnezzar took Sidon by assault with dreadful carnage, and invested Tyre, the siege of which, one of the most celebrated in history, lasted for 13 years, though its issue is strangely enough altogether uncertain. It seems probable, however, that the part of Tyre which was built on an island resisted all the efforts of the besiegers. After the siege there seems to have been much internal disturbance. Judges or suffetes took the place of kings, and there is some reason to believe that to a certain extent Tyre like the rest of the Phœnician cities acknowledged the sovereignty of Babylon. The fall of Babylon before the arms of the Persians was followed at no long interval by the submission of the whole of Phœnicia to Cyrus or his successor Cambyses. Under the Persian monarchy the Phœnician navy was a regular and very important element of the imperial power. But the internal constitution of the cities does not seem to have been disturbed, and the native line of kings continued to reign under the protection of the Persian sovereign, whom they acknowledged as their liege lord. The commerce of the cities flourished by the rich traffic of Arabia and the East which passed through their hands, and their manufactures of purple and glass were in full activity. Throughout the long struggle between Greece and Persia the Phœnicians contributed the naval forces of the Persian monarchs. During the reign of Darius Ochus, Sidon, which had now taken the lead among the Phœnician cities, revolted, and after a desperate struggle was betrayed by Tennes its king to the Persians in 350 B. C., and was utterly destroyed with all its inhabitants, except a few who were absent, and by whom the city was subsequently rebuilt. When Alexander invaded the Persian empire, the Sidonians submitted to him readily, but Tyre resisted, and after a siege of 7 months was taken by treachery and reduced to ashes, part of the inhabitants being slain and the rest sold as slaves. Alexander rebuilt the city, but it never regained its former importance. Phœnicia was incorporated into a Macedonian province with Syria and Cilicia, and its commerce again flourished as in former ages. It afterward fell under the dominion of the Seleucidæ. About 65 B. C. the Romans conquered the country, and from that time till now Phœnicia has shared the fate of Syria. During the crusades Tyre was a port of consequence, but under the rule of the Turks, and especially since the commercial changes consequent upon the discovery of the passage to India by the way of the Cape of Good Hope, it became what it remains to this day, "a rock for fishermen to spread their nets upon."—The language of the Phœnicians bore a very close affinity to the Hebrew, as is abundantly shown by the unanimous testimony of the ancient grammarians and the fathers of the church, who frequently speak of the languages as nearly identical. Numerous words preserved as Phœnician or Carthaginian by the Greek and Latin writers correspond exactly with the Hebrew, as Baal, Adoni, Malka, Suffeta, Gadira, Susa, Alpha, and Tur; and the only satisfactory results in interpreting the Phœnician monuments and coins have been obtained by making the Hebrew the key to their explanation. Out of 94 words in the recently discovered tablet of Marseilles, 74 occur in the Old Testament. Beside inscribed coins and stones, there remains a curious monument of the Phœnician language in its Carthaginian branch in the *Pœnulus* of Plautus, in which one of the characters of the play, a Carthaginian, utters some sentences in his native tongue. In 1837 Gesenius published his *Scripturæ Linguæque Phœniciæ Monumenta*, containing all the extant remains of the language then known, to the number of about 1,000 words. Additions to the vocabulary have since been derived from ancient Carthage, Sidon, &c., and much is expected from M. Renan, who is now exploring Phœnicia. In its original form the literature of Phœnicia has wholly perished, and little has been preserved through Greek translation. Its oldest productions appear to have been philosophical and theogonical, and the Greeks attributed to the Phœnicians Sanchuniathon and Mochus a greater antiquity than that of their own oldest writers. The other writers of Phœnicia are all known to us under Greek names, as Theodotus, Hypsicrates, Philostratus, Dius, Menander, and Hieronymus. A long extract from Dius relating to the intercourse between Hiram and Solomon is given by Josephus, who also quotes from Menander, by whom the histories of the Phœnician cities were written from their local records. The most considerable of these extracts is from the writings of Sanchoniathon, preserved by Eusebius in his "Evangelical Preparation." (See SANCHONIATHON).—The principal modern works on Phœnicia are Movers's *Die Phönizier;* Heeren's "Historical Researches," vol. ii.; and Kenrick's "Phœnicia" (London, 1855).

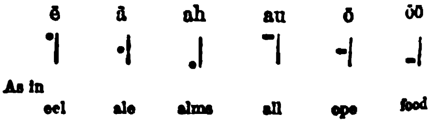
PHŒNIX (Gr. φοῖνιξ), a fabulous bird to which many marvellous qualities were attributed by ancient authors. According to one legend, it lived in Arabia, resembled an eagle, with wings partly red and partly golden, and upon arriving at the age of 500 years built itself a funeral pile of wood and aromatic gums, and, lighting it by the fanning of its wings, was consumed to ashes, out of which arose a new phœnix. The myth is undoubtedly of eastern origin, as similar stories of marvellous birds occur in the literature of Persia and India. By poets and imaginative authors of every age the phœnix has been regarded as the emblem of immortality. The fathers of the church employed it to illustrate the doctrine of the resurrection; and several of the Roman emperors used it on coins to typify their own apotheosis, or the return of the golden age under their rule. Métral's work, *Le phénix, ou l'oiseau du soleil* (Paris, 1824), contains a *résumé* of all that has been written in ancient or modern times upon the subject.

PHŒNIXVILLE, a manufacturing town of Chester co., Penn., on the Schuylkill river, at the mouth of French creek, and on the Philadelphia and Reading railroad, 28 m. from the former and 30 m. from the latter; pop. in 1860, 4,433. There are mines of iron, copper, and lead in the vicinity, and it has extensive iron manufactories, producing great quantities of railroad iron and nails. A rolling mill, supposed to be the largest in the United States, employs from 1,200 to 1,500 men. The Schuylkill navigation company's canal passes through the town. Phœnixville has a lyceum, a newspaper office, and several churches.

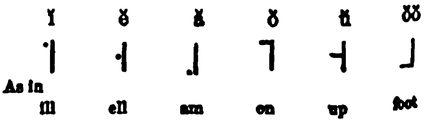
PHONOGRAPHY (Gr. φωνη, voice, and γραφω, to write), a system of shorthand invented by Isaac Pitman, of Bath, England. It was first published in 1837, and has since been greatly modified. It professes to be based upon an analysis of the sounds of the English language, and from this fact was at first called sound hand. The consonants are represented by straight lines and curves. The first 16 in the table below are in pairs, represented by light and by heavy straight lines and curves, corresponding with their near relation in sound. Thus the first sounds in *p*in and *b*in are made by the same articulations, the lips being first compressed together, and then thrown suddenly apart by the expulsion of breath. The first is a whispered sound, the second a sub-vocal, in the latter the muscles of the larynx being called into action. The same principle is applicable to the remainder of the pairs. *T* and *d* are represented by perpendicular marks, the one thin, the other thick; and they stand for thin (whispered) and thick (voiced) sounds. Take the first sounds of *t*in and *d*in; experiment will show that the articulations are similar, the tongue coming in contact with the roof of the mouth near the roots of the upper front teeth in the production of either sound. The third pair, *ch* and *j*, are also made by articulations resembling each other, as observed in the first sounds of *ch*est and *j*est. The same is true of *k* and hard *g*, as in *K*ate, *g*ate; of *f* and *v* in *f*ine and *v*ine; of the pair marked *th*, whispered as in *th*in, vocalized as in *th*is; of *s* and *z*, in *s*eal and *z*eal; of *sh* and *zh*, in *s*ure and *az*ure. It is to be particularly observed that the powers of these letters are referred to above, and not their names of *pe, be, te, de, ka, ef, ve,* &c. The following is a table of the single consonants:



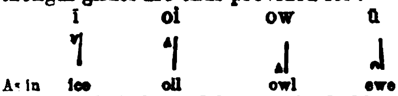
The vowels are represented by dots and short dashes, which are made heavy and light to represent long and short vowels. The 6 long vowels are:



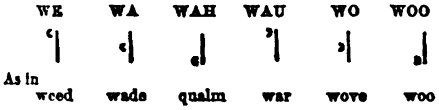
The short vowels are:

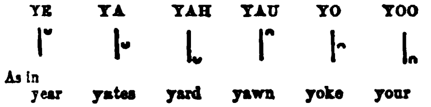


By a change of position, the heavy dot is made to represent 3 vowels; the light dot, 3; the heavy stroke, 3; the light stroke, 3; in all, 12. They are placed respectively at the beginning, middle, and end of a consonant. The upright stroke to which the vowels are placed in these examples is no part of the vowel sign; it is the phonographic sign for *t*, and is employed merely to indicate the positions of the vowels, namely, 1st, 2d, and 3d place. The diphthongal glides are thus provided for:



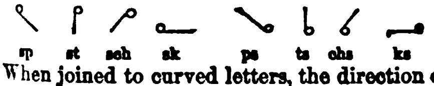
The sounds indicated by *w* and *y* hold a middle place between vowels and consonants; that is, they are less open than vowels, and less obstructed than consonants. They are sometimes called coalescents, because they are never used except immediately preceding a vowel with which they closely coalesce. By prefixing respectively the simple sounds of *w* and *y* to the simple vowels given above the reader will have this series, which is represented as follows:





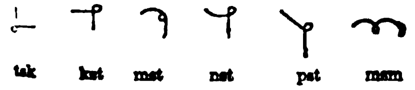
W and *y* are also furnished with single forms, as seen in the table of consonants. The briefer sounds, as heard in *yet*, *yam*, *yonder*, &c., are indicated by lighter marks. *W* and *y* prefixed to the diphthongs ī, *oi*, and *ow* are thus represented:

The aspirate *h* is never used except immediately preceding an unobstructed or vowel sound, and is simply an initial, audible breathing through the position which the vocal and articulating organs assume to pronounce any given vowel. This unobstructed whisper *h*, though it has as many different powers as there are vowels, still, being thus uniformly used, is fittingly represented by a small dot placed immediately before any vowel, thus indicating that the vowel is to be preceded by the aspirate. The stroke sign for *h* is employed when a word consists of a vowel and aspirate only, as in *hay*, *hue*, &c.—*S*, the most frequently occurring consonant in the language, is represented by a circle, which is made somewhat thicker for *z*. The circle is joined to straight letters thus:



When joined to curved letters, the direction of the curve is followed, thus:

When occurring between two consonants, it is written in the shortest direction, as:



The above is the phonographic alphabet proper. For greater facility in writing, however, several series of abbreviations have been adopted. The following is a

TABLE OF SINGLE AND DOUBLE CONSONANTS.

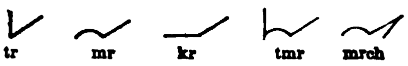
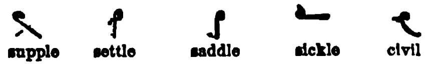
R is also represented by an additional sign, namely, a slanting up-stroke, which is always written and joined in an upward direction, thus:

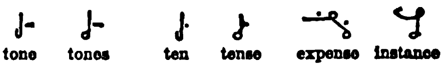


Consonantal diphthongs in which *l* and *r* are used in conjunction with all the other consonants are of very frequent occurrence in the language. These glides being uttered with almost as little effort as simple sounds, they are appropriately represented by a slight modification of the simple letter. (See the 2d and 3d columns of the table above.) From the *pr* series of double consonants a treble series is formed by making the hook into a circle, thus:

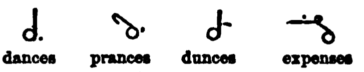
S is prefixed to a consonant of the *pl* series thus:



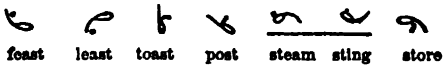
S or *s* is added to the *n* series by making the hook into a circle, thus:



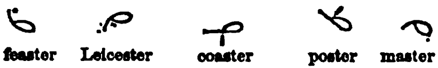
The circle is enlarged for *nses*, thus:



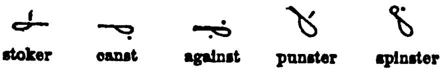
St is written by a loop half the length of a straight consonant, as:



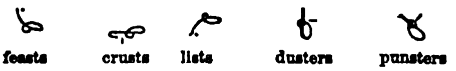
A larger loop or oval represents the treble consonant *str*, thus:



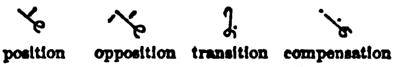
These loops may be added to the *pr* series of consonants, and to the *n* hook when final, thus:



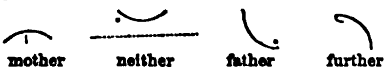
A final *s* may be added by continuing the stroke of the loop, thus:



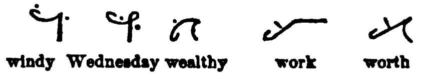
A hook made by continuing the *s* circle to the other side of the consonant adds *tion*, as:



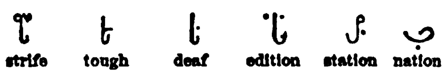
A curved consonant written twice its usual length adds *thr*, as:



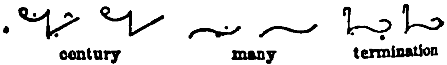
The vowel sign for *w* may be prefixed to *l*, *r* (upward), *m*, and *n*, thus:



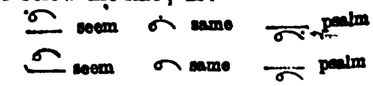
A final hook on the right hand side of straight consonant signs represents *f* or *v*; the termination *tion* is expressed by a larger sized final hook:



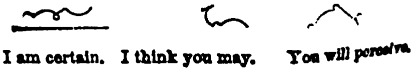
Halving a consonant adds *t* or *d*, according as the consonant is thin or thick. (See the last column of the table.) The general rule for writing consonants is to write them from top to bottom, and from left to right. *L*, however, when standing alone, is written upward; *sh* may be written upward or downward, as is most convenient; when two straight consonants, such as *pp*, *kk*, follow each other, they are made by a continuous line double the length of a single consonant.—With the exception of certain prefixes, affixes, and abbreviated words termed grammalogues, which it is unnecessary to present, the above is the first or corresponding style of phonography, according to the 9th edition. A 10th edition, however, has been published in England, in which the vowel scale has been changed to the following order: *ah*, *ā*, *ē*; *ă*, *ĭ*, *ĕ*; as in *alms*, *all*, *eel*; *at*, *it*, *et*. But as it has not been adopted by authors of text books or by students in this country, it has not been followed in this account of the system. It will be seen that phonographic spelling harmonizes with the pronunciation of words. Each sound is represented by a special character; therefore to write any given word phonographically, its several sounds must first be ascertained; the student should then write the phonographic letters which compose them.—While phonography is strictly a system of shorthand, each letter being made by a single motion of the pen, the facility it affords for abbreviation renders it peculiarly adapted for reporting purposes. The large outlines of the consonant signs, as compared with the dots and short dashes which are used to represent vowels, will be likely to suggest the word of which they form a part, even though the vowels are omitted, as will be seen by a few examples:



The principle of position is hardly of secondary importance. Three positions for words are recognized, corresponding with the three vowel positions. Words which are to be indicated by the position they occupy are written as follows: those whose accented syllable contains a first place vowel in the first position, or above the line; containing a second place vowel, upon the line; containing a third place vowel, through or below the line; as:



(In this and some previous examples, the dotted line indicates the line written upon.) In the reporting style, beside this principle of abbreviation, a great many phrases are written without lifting the pen, and are called phraseograms, the employment of which is generally necessary in making verbatim reports. From 6 to 10 words are sometimes embraced in a phraseogram, and it is generally conceded that they are more legible than the same words written separately, on a like principle that numerals, which embrace a smaller space and are taken in more readily by the eye, are more easily read than when the number is spelt out; as for instance, 1861 is read with greater facility than eighteen hundred and sixty-one.



Phonography differs from other systems of shorthand chiefly in its more extended phonetic basis, and in the simplicity of its alphabet, the simplest geometrical characters having been adopted.—Since the invention of phonography its dissemination has been very rapid. It is the system generally adopted by reporters in this country and in Great Britain. It is also used by professional men, by ministers for writing their sermons, and by lawyers to take notes of evidence, its legibility rendering it peculiarly adapted to these purposes. Four monthly periodicals in phonographic characters are published in England, one in Australia, and two in the United States. There have been 600,000 copies of the system sold in England and the British colonies, and probably about half that number in the United States. Including the yearly volumes of the phonetic periodicals, about 100 volumes of engraved phonographic literature have been issued up to 1861.

PHOSPHORESCENCE (from resemblance to the light of phosphorus when slowly oxidized, or directly from the Gr. φῶς, light, φέρω, to bear), a luminousness or light, usually faint, and emitted continuously rather than by flashes, but during a time varying from a small fraction of a second to several minutes or even hours, by certain organized bodies, living or dead, and also, after exposure to extraneous sources of light, by a large number of mineral bodies in the solid state. The phenomena that have ordinarily been included under the term phosphorescence are in reality widely different, and they require to be properly discriminated. The light given out by certain insects has been observed from very early times. The ancient navigators were familiar also with the luminosity sometimes appearing on the surface of seas or bays; and these appearances they termed "meteors of the sea." In rare instances the human body is said to have appeared luminous, as have also certain plants, but especially their flowers. Several fungi and agarics are said in this way to emit light. Mr. James Drummond describes species of agaric, growing on the trunks of banksias, near Swan river, which gave at night a light enabling him to read; and certain rhizomorphous fungi growing in the coal mines of Dresden have long been celebrated for the illumination, feeble indeed, which they throw around them. The flowers of nasturtium, orange lily, African marigold, sunflower, and others, all of orange hue, are said to show an intermittent light during warm summer evenings, toward twilight; but Professor Allman suggests that this may be an optical illusion. The luminousness of putrefying fish, shell fish, or other animal substances, and of decaying wood, is well known; the latter is the appearance vulgarly termed "fox fire." Diamonds, especially the yellow, exposed for a time to the solar rays (insolated), when carried into a dark place, emit for some time a light which pales gradually until entirely extinguished. So of oyster shells calcined with sulphur, and many chemical preparations and other minerals, the class of bodies possessing this property being named phosphors or phosphori. Thus, under the single term phosphorescence, are grouped at the least 5 distinct kinds of phenomena, agreeing in the fact that the light and the circumstances producing it are peculiar, and that the rays emitted are, so far as experiment can yet detect, luminous only, or at least destitute of accompanying heat, viz.: 1, light of insects and other animals, due to feeble combustion of matters produced within their organism and during the living processes; 2, the same, due to direct evolution or vital action, and so analogous to the production of electricity, and the nervous and muscular forces; 3, evolved in ways similar to the two foregoing, by plants; 4, due to slow combustion, attending decay, of organized materials; 5, due, in mineral bodies, to an agitation produced within their substance, during exposure to an extraneous source of light, and radiated with lessening intensity, as such agitation decreases, down to the point of extinction. It will be proper to consider further, in this place, only the last of these cases; the first and second being treated of in the articles FIREFLY and GLOW-WORM, and the others being less important. In the articles LIGHT and COLOR it is shown that an illuminated body is in reality one that is made secondarily or temporarily luminous, by reason of the falling of light from some other source upon it. Most frequently, the color of this temporary luminosity agrees with that of the whole or some part of the rays exciting it. Some bodies, however, change the character of the rays before reëmission; thus, violet light, striking a colorless solution of sulphate of quinine, is emitted blue. (See FLUORESCENCE.) So far as the eye detects, this and ordinary illumination cease the instant the rays of the exciting luminary cease to be received upon the body. But the truth probably is that no body ceases to be visible the instant it ceases to receive light. The luminous agitation and secondary emission persist after withdrawal of the illuminating rays; but, in liquids and gases (save oxygen and common air), in black bodies, and in all metals, such persistence is so brief and fugitive, that it has thus far escaped detection. In other solid bodies, the persistence of light-giving after cessation of light-receiving is either, as in diamond and fluor spar, of such duration as to be examined at our leisure, or, as in a still larger proportion of these bodies, so brief as to have been unsuspected until tested by very ingenious experiment. Now, this continuing secondarily emitted light is phosphorescence, in the last of the 5 forms named above. This view agrees substantially with that put forth by Prof. J. W. Draper, of New York, as the result of observations undertaken by him as far back as the year 1840, and renewed since that time. Among the conclusions arrived at by him are, that a phosphorescent, even at its maximum of glow, has not perceptibly changed its volume; that there is no attendant development of electricity; that the intrinsic brightness of a phosphor is very small, the maximum of a fine specimen of chlorophane (a variety of fluoride of calcium) being but $\frac{1}{3040}$ part as intense as the flame of a small oil lamp; and that some phosphors are excited to greater luminosity by light from the sky, or that through a violet glass, than by direct sunlight. If we adopt the view of M. E. Becquerel, this is probably because, when the temperature is raised, as it is by the direct sunbeam, the phosphorescence is more rapidly expended, and even during insolation. Other conclusions of Draper, among them that phosphorescence of this form is attended with slight increase of sensible heat, are rendered questionable by results of the later and extremely patient researches of Becquerel, whose exhaustive paper on this subject occupies the entire number of the *Annales de chimie et de physique* for Jan. 1859. This physicist examined in order the mineral and organic substances capable of being rendered self-luminous after some moments' insolation, or exposure to other sufficient light; and he greatly facilitated his investigations by the invention of an instrument which he has termed a phosphoroscope. In this, a cylinder of wood, about 1 inch in diameter and 7 inches long, is so placed in a projecting angle in the side of a black box, that three fourths of its surface are, during any revolution, outside the box, and in the darkened room in which are the spectators; the remaining fourth being in the box, and illuminated by the voltaic light, and the escape of this about the edges of the cylinder being prevented by properly attached strips of black velvet. The cylinder can be turned at any speed up to 800 revolutions per second; and by added mechanism the actual velocity can be indicated. The cylinder is coated over with fine crystals or powder of the body to be tested. If, then, the persistence of light be but $\frac{1}{20}$ of the most rapid revolution named, after illumination has ceased in consequence of the surface leaving the source of light within, so that its duration is but the $\frac{1}{8000}$ part of a second, still the phosphorescence will come into view along the emerging side of the cylinder without, and sufficiently to be visible. The rate of revolution being known, and the part of the outer surface of the cylinder that becomes lighted up observed, the duration of the phosphorescence for any given substance and modification of substance is readily determined. The cylinder, if coated with an ordinary phosphor, and rapidly turned, appears in the dark room luminous all over. If the body be very briefly phosphorescent, a velocity is readily found at which the light shall show along the emerging side of the cylinder; and then, turning faster, it spreads over half or more of the exposed surface a soft gleam, white, blue, or green, &c., dying away into a portion totally dark. Thus, in this apparatus, time is expressed to the eye in space, and so measured. With it, M. Becquerel found that time is consumed in elevating the phosphorescence of any substance to its maximum; that, generally, the phosphorescence is less brilliant than the incident light, exceptions being that it is in many bodies best excited by the feeble violet, or even by the dark rays beyond the violet; that, generally, its intensity is independent of the duration of exposure, but is a function of the intensity of the exciting rays; that both intensity and color depend much on certain physical modifications that can be produced by peculiar modes of preparing the substances examined, and on temperature—the sulphuret of strontium, for example, obtained by reaction of S on Sr above about 600°, emitting a violet glimmer at low temperatures, blue at 40° C., greenish at 70°, greenish yellow at 100°, and orange at 200°; that the total action is greater and the gleam longer as the temperature is lower, while, with the same substance, the color may vary at different periods after exposure; that, however, the phenomena are not due to chemical causes, but consist essentially in a physical change, or, as the author expresses it, depend on variations of equilibrium in the molécular condition of bodies. By prosecuting the subject from the point of view thus obtained, Becquerel has discovered more brilliant phosphors than any before known; especially the sulphurets of the alkaline earths, barium, strontium, and calcium. After these, in order, he places most varieties of diamond, and the fluoride of calcium; then, many other bodies luminous only for a few seconds or part of a second, including other compounds of earths and alkalies, the alkalies themselves, succinic and oxalic acids, borax, &c. Among organic bodies, dried paper, silk, cane sugar, milk sugar, teeth, &c., are prominent. Mr. Phipson has lately found that milk sugar, as well as cane sugar, becomes luminous upon concussion, or on fracture; while, to secure a brilliant phosphorescence from the nitrate of uranium, it is only required to shake briskly in the dark a bottle containing a certain quantity—a pound or more—of the crystals of this salt. It was previously known that the human epidermis possesses this property; the hand, for example, if exposed to the sun's rays, and then immediately withdrawn into a dark room and held before the eyes, being visible for a short time after it has ceased to receive the light. So, again, if a piece of the mineral apatite, or of fluor spar, be heated, it will while yet far below redness emit a glow of increasing intensity, and so has become by some internal change a source of light originated in the way of phosphorescence. A similar effect is observed when two pieces of quartz are rubbed together in the dark. M. Becquerel found that heat accelerates the phosphorescence of any body, rendering it more intense, and, after removal of the exciting cause, correspondingly more brief; and also, that to some extent the color of the emitted light depends on the molecular condition of the body; that this color, *i. e.*, the refrangibility of the emitted light, is generally lower, and hence the wave length greater, than that of rays exciting it; while, in applying the different rays of the spectrum to show the phenomenon, the result was usually an increase of brilliancy under the action of the more refrangible rays, and greatest often above the violet, though there were also at different places in the spectrum bands of no action; that the lower bands of color in the spectrum often neutralized, wholly or in part, the effect of the upper; and that, nevertheless, different bodies are often susceptible of shining only within different limits in the spectrum. Aragonite, Iceland spar, and glass give vivid light during 15 to 20 seconds; chlorophane and some diamonds, though less luminous, shine for more than an hour. The electrical light admirably excites phosphorescence; best of all, the violet arch formed between the poles in tubes containing rarefied air. With the electric spark, the time required to induce a perceptible glow is not greater than $\frac{1}{3000}$ of a second; but to reach a maximum effect, the time is greater. Finally, phosphorescent light was not found to affect the thermometer, nor to occasion chemical change. A practical consequence of these investigations, of singular character, was arrived at; namely, that the flint glass prisms and lenses of optical instruments may be expected to phosphoresce, or act as luminous sources, the new light mingling with that which is transmitted, and modifying the image or vision accordingly. Perhaps the most interesting of Becquerel's discoveries is one yet to be stated. Since the electric light, if transmitted through glass, loses mainly the rays which excite phosphorescence, the experiment of passing the former light over fragments of the body examined, in the rarefied air tube, was resorted to; but here it was frequently found that a glow upon these fragments, usually differently colored from that of the electric light at the time, and which lasted during the electric illumination, gave place after the current was cut off to light of a different color, and which persisted for a longer or shorter period; in other words, fluorescence and phosphorescence here occurred in succession. Hence Becquerel inferred that the two phenomena are essentially one, and different only in the time during which in the two cases the excited condition lasts. Experiments with the phosphoroscope speedily confirmed this conclusion. If, for example, the cylinder was covered with fine crystals of nitrate of uranium, its revolutions, at any moderate velocity, brought no light into view; at very high rates of revolution, it appeared along the emerging side; but it could not, by any speed practicable, be made to cover the whole cylinder. Thus it was made evident that fluorescence is a phosphorescence accompanying the action of the exciting rays, and on their removal almost instantly falling to inactivity. In some of the experiments, oxygen gas and common air, through which the electric current was passed, retained distinctly for some time after its cessation the phosphorescent state. M. Becquerel apprehends that these researches must tend to elucidate the manner in which luminous vibrations become modified in consequence of the entrance of the rays within substances of different kinds, thus leading toward an explanation of the phenomena of color. He regards them as supporting the undulatory theory of light; and he is led to the general conclusion that luminous vibrations, transmitted to many bodies, perhaps to any body, compel its molecules to vibrate for a time, and with an amplitude and wave length dependent, not alone on the chemical constitution of the mass, but also on its physical condition.

PHOSPHORUS (Gr. φῶς, light, and φέρω, to carry), an elementary body represented by the symbol P. Its chemical equivalent is 32; specific gravity 1.77, and that of its vapor 4.355. It was discovered in 1669 by Brandt of Hamburg in the solid ingredients left by evaporating urine. For 100 years this was the only known source of it. The process of obtaining it was expensive and understood by a few only. In 1680 Robert Boyle's receipt for making it was published in the "Philosophical Transactions of the Royal Society;" and at this time a chemist in London, named Hanckwitz, prepared it to be used for igniting sulphur matches, a little piece of the phosphorus being made to inflame by rubbing it in paper. In 1769 Gahn and Scheele found that it was an ingredient of bones, and made known the method of separating it. Afterward it was found in various rocks, especially in combination with lime in the mineral apatite or phosphate of lime. By the decomposition of the rocks containing it, phosphorus passes into the soil and is thence taken up by plants, of many of which, especially of the grains used for food, it forms an important element. Thus it is received into the animal system, and in this is an essential ingredient in the composition of the brain and nerves. Phosphorus is a semi-transparent, nearly colorless substance, flexible, and so soft that it can be cut with a knife, and then exhibits a waxy lustre. It is tasteless, but exposed to the air it emits a vapor having an odor like that of garlic. This vapor, as also the phosphorus itself, is luminous in the dark. It melts at 111.5°, and, if beneath an alkaline liquid, may if undisturbed remain fluid when cooled. It takes fire in a warm atmosphere, and is consequently most safely kept under water, in which liquid it is insoluble. Even at ordinary temperatures it slowly and insensibly consumes and at last disappears. If this process takes place in a bell glass over water, oxygen is found to be absorbed as in ordinary combustion, and the process ceases if the supply of oxygen is insufficient for complete combustion. Phosphorus boils at 554°, and it may then be distilled, and thus be obtained in purified form. Great precautions, however, are requisite in the arrangement of the apparatus on account of its ready inflammability, and the severity of the burns caused by it. The solvents of phosphorus are ether, naphtha, dichloride of sulphur, and bisulphuret of carbon. From its solution it may be obtained crystallized in rhombic dodecahedrons. Several allotropic forms of phosphorus are known, of which that described by Schrötter (*Annales de chimie* [iii.], xxiv. 406) by the name of the red amorphous phosphorus presents some striking differences from the ordinary stick phosphorus, and ought especially to be familiar to those engaged in the manufacture of matches, for which phosphorus is largely employed, inasmuch as it is entirely free from the poisonous vapor which renders the use of the common article extremely dangerous to the health of the workmen. This variety is formed by keeping stick phosphorus several hours at a temperature between 446° and 482° in a retort filled with hydrogen or carbonic acid, neither of which exerts any action upon it. Distillation takes place, and both sorts of phosphorus are obtained. They are separated by treatment with bisulphuret of carbon, which dissolves the ordinary phosphorus and leaves the red in an amorphous powder. This is then fused and afterward solidified. It is hard and brittle, not so luminous nor so highly inflammable as the other kind, and has not the same poisonous properties. It undergoes no change in the air and emits no odor. Its specific gravity is 2.14. At about 482° F. it takes fire and burns with dazzling brilliancy. If prepared at as high a temperature as it will bear, it may acquire the color of vermilion. It has been manufactured in England upon a large scale with a view to its substitution for ordinary phosphorus in matches; but its preparation is attended with considerable danger, and its use involves increased expense. Common phosphorus is prepared from calcined bones, which are composed of carbonate and a basic phosphate of lime. Those of the sheep furnish the largest proportion of phosphorus, and are most easily acted on by acid. The bones being pulverized are mixed with two thirds their weight of strong sulphuric acid and 6 times their weight of water, and the mixture after being well stirred is left for 24 hours. The carbonate of lime is decomposed, the lime being converted into a sulphate; and the basic phosphate, losing two thirds of its lime, is converted into a soluble acid phosphate known as the superphosphate, which retains all the phosphorus. The change is expressed by the following formula:

$$\overbrace{3\,CaO,\,PO_5}^{\text{Bone ash.}} + \overbrace{2\,(HO,\,SO_3)}^{\text{Sulph. acid.}} = \overbrace{2\,HO,\,CaO,\,PO_5}^{\text{Superphosph. lime.}} + \overbrace{2\,(CaO,\,SO_3)}^{\text{Sulph. lime.}}.$$

By filtering through a linen bag the solution is separated from the insoluble sulphate of lime. It is then evaporated to the consistency of a sirup, and being mixed with one fourth its weight of powdered charcoal is heated and well stirred until it becomes a dry powder. This is placed in an earthen retort, which is luted on the outside with fire clay and borax to render it less porous, and the retort is gradually heated to redness. The superphosphate of lime is now decomposed; the basic phosphate is reproduced by the escape of the excess of phosphoric acid and water, both of which are decomposed as they come in contact with the incandescent charcoal, and produce phosphorus, carbonic oxide, and hydrogen. The basic phosphate remains in the retort. The other products pass through a copper tube into a receiver containing water, in which the phosphorus condenses in yellow drops, while the gaseous bodies pass off through an open escape pipe. Almost a pound of phosphorus may be obtained from a quart retort filled with the materials. The phosphorus is purified by fusing it under warm water and then squeezing it through wash leather. It is moulded into the form of sticks by introducing a glass tube, slightly tapering, into the melted substance, and causing this to ascend by sucking. When sufficiently full the opening at top is closed with the finger, and the tube is drawn out and plunged into cold water. When the phosphorus hardens it is pushed out of the larger end of the tube with a rod. Another method has been employed by which the melted phosphorus is made to flow into horizontal glass tubes, of which one end is kept in water heated above 111° and the other in cold water. Out of the cold end the substance may be drawn almost in a continuous stick.—Another method of making phosphorus is recommended in the "American Journal of Pharmacy," vol. xxiv. p. 167, by which the calcination of the bones is avoided. These are digested for several days in dilute nitric acid, and from the solution acetate of lead throws down the phosphorus in an insoluble phosphate of lead. This, being washed and dried, is heated red-hot in a crucible, and is then mixed with charcoal powder and distilled in the usual way. The bones deprived of their earthy matter may be used for the manufacture of glue. The shavings of horn are well adapted for this use, as they contain twice as much phosphate of lime as ordinary bone. From the residue a nutritious jelly may be obtained.—The manufacture of phosphorus is carried on chiefly in France, Prussia, Baden, Bavaria, Austria, and Sardinia. In 1844 all that was consumed in England was imported from the continent of Europe, and within the memory of those now living its cost was 4 guineas per pound, while now it is worth less than 3*s*. The consumption, however, does not appear to have largely increased in that country, notwithstanding the manufacture has been there introduced. The importation ceased altogether in 1850, and other materials are largely substituted for it in the manufacture of matches. The production of England and France together in 1859 was estimated at about 300,000 lbs. The consumption is almost wholly for matches. It is used in medicine, acting in small doses as a general stimulant. The form in which it is administered is generally its solution in oil, an ounce of almond oil taking up 4 grains of phosphorus, of which from 5 to 10 drops are given for a dose. It has also been given in cod liver oil, and in chloroform. Recently a preparation called pyrophosphate of iron has come into extensive use as a tonic and alterative, in which phosphorus in the form of pyrophosphoric acid is an essential ingredient. In many cases where death has become imminent from exhaustion of the vital forces, as in the last stage of all severe continued fevers, such as typhus, yellow, and other fevers, phosphorus reanimates the vitality, and furnishes nature with the means of effectually resisting the disease, eliminating by the natural excretory outlets of the system its material causes. It is useful in all acute eruptions when the disease has retreated from the surface, as in measles, small pox, erysipelas, &c., as well as in malignant pustule. It is often successfully used in many chronic affections when attended with much debility, as gout, rheumatism, paralysis, excessive debility, amenorrhœa, sterility, impotence, blindness, deafness from paralysis of the nerves of sight and hearing, &c. The homœopathists reverse almost all these indications, and use it in many acute fevers and inflammations, especially in inflammations of lungs and of the female breast, in croup and hoarse coughs. Phosphorus, being a component portion of the nervous tissue, is as useful in many nervous affections as iron is in diseases of the blood. Taken in substance into the stomach it acts as an irritant poison, for which the proper antidote is a speedy emetic. Copious draughts of water should be swallowed in case of solutions of phosphorus having been taken in large quantity; and magnesia added to the water would serve to neutralize any acids produced in the stomach. It is also recommended in combination with 3 times its weight of chlorine water. The vapor of phosphorus, to which the makers of matches are exposed, causes a disease of the jaw bone which becomes carious, so that it has sometimes been removed as the only means of saving the life of the sufferer. (See MATCH.)—The compounds of phosphorus with oxygen are 4 in number, viz.: phosphoric acid, PO_5; phosphorous acid, PO_3; hypophosphorous acid, PO; and oxide of phosphorus, P_2O. The first, which is the most important, is obtained in the form of a white, flocculent, very deliquescent powder, by burning phosphorus in oxygen or atmospheric air. It has a great affinity for water, and may be obtained combined with it in 3 different proportions, severally known as the proto-, deuto-, and trito-hydrate of phosphoric acid. The second of these ($2HO, PO_5$) is the pyrophosphoric acid named above, and used in medicine in combination with soda, and also with lime, and again with iron. Its name is derived from the method of preparing its combination with soda by applying heat to the rhombic phosphate of soda. The first, known also as metaphosphoric acid and glacial phosphoric acid, is much employed in processes connected with dyeing, calico printing, enamelling, and the purification of some oils and fats, in preference to other acids that have been used for the same purposes. It is obtained by digesting finely ground bone ash with diluted oxalic acid and evaporating. Numerous natural combinations of phosphoric acid with bases exist among minerals, the most important of which is the phosphate of lime or apatite, consisting of phosphoric acid 42.26, lime 50.00, and fluorine 3.77. Limestones that contain it in considerable quantity make valuable manures; and the bones that are used for the same purpose derive their fertilizing qualities chiefly from the phosphate of lime. Guano derives a large share of its useful properties from the salts of the same acid. What is called the superphosphate of lime is an acid phosphate produced by treating ground bones with one fourth their weight of sulphuric acid. The triphosphate is converted into an acid phosphate, and the mixture consists beside of sulphate of lime and the gelatinous portions of the bone, all of which possess fertilizing properties.

PHOTIUS, patriarch of Constantinople, and reputed author of the Greek schism, died in 892. The place and time of his birth are not mentioned. He was related by the marriage of his uncles to the patriarchal and imperial houses; and in 857, when he first appears in history, he was the secretary of state to the eastern emperor. He had made himself necessary both to the emperor Michael III. and to his minister Bardas. A quarrel with the patriarch Ignatius, who opposed the forcible removal of the mother and sisters of the emperor to a convent, seemed to require a change in the occupancy of the see. Ignatius was sent into exile, and though he could not be persuaded to resign his dignity, his place was declared vacant, and Photius was installed as his successor. The election was irregular in several particulars. It was made by the will of the Cæsar and not by the authorities of the church; the candidate was a layman, and moreover already a schismatic, adhering, as it was said, to the party of the Sicilian bishop against the Byzantine primate. These formidable difficulties did not, nevertheless, hinder his promotion. In 6 days he passed through the various grades, and was ordained patriarch, his friend Asbestas of Syracuse, the enemy of Ignatius, presiding at the ceremony. The consent of the neighboring bishops was with difficulty obtained. Deceived by a stratagem, they became the enemies of the usurper, while they seemed to uphold him. The timely embassy which Photius sent to Rome with the false statement of the voluntary resignation of

Ignatius, and with assertions of the orthodoxy of the new incumbent, gained over for a time the pope, Nicholas I. A council at Constantinople of 318 bishops, in 861, confirmed the election, deposing Ignatius and condemning him to degradation and exile. This decree, however, was soon annulled by another council which was called at Rome by the pope, in which Photius was anathematized in turn, and ordered to relinquish his claim. Photius at first treated this summons with contempt, and called at Constantinople still another council in 867, in which he excommunicated the pope, and accused the Roman church of heresy. On the death of the emperor Michael and the accession of Basil to the eastern throne, Photius was banished and Ignatius restored; and in a council held in 869 the acts of the unlawful council held by Photius were solemnly abrogated and its records burned. After an exile of 8 years, Photius was allowed to return to Constantinople, where he speedily regained favor; and in 878, on the death of Ignatius, he obtained the consent of both emperor and pope to his assumption of the patriarchal place. The promise which the pope required was not, however, fulfilled. Photius opposed the restoration of the Bulgarians to the Latin church, and did not recant his own heresies. A new excommunication came from Rome, the sentence of the former Roman council was reaffirmed, and in 886 Photius was finally banished by the emperor Leo to an Armenian convent, where he died.—Photius has importance in history as the founder of the Greek schism, as a dogmatist, as a philosopher, and as a literary critic. Though he did not consummate the separation between the Greek and Latin churches, he created a division which was never healed, and after him no confession of supremacy could be wrung by the pope from the Greek patriarch. He drew up charges against the Latin church, that they shortened the season of Lent, refused to allow married men to enter the priesthood, denied to priests the right to administer the chrism, and above all that they taught the double procession of the Holy Spirit. Of his numerous works, the most important is the *Bibliotheca*, which contains fragments of nearly 800 Greek prose writers, most of whose works are lost, with critical remarks thereon. Editions of this work have been published in Augsburg (1601), in Geneva, with a Latin translation (1611), and in Berlin by Bekker (1824). He also left a "Lexicon" (Leipsic, 1808; London, 1822); the "Nomocanon," a collection of canonical decrees, epistles, and statutes concerning the church (Paris, 1615); a collection of 248 letters (London, 1651); theological tracts, contained in Combefi's supplement to the *Bibliotheca Patrum;* and a treatise on "Consolation," edited by Rittershusius (Nuremberg, 1601). Some additional fragments of his writings are contained in the collection published by Cardinal Mai in 1825–'7 from the MSS. in the Vatican. An excellent monograph on the life and influence of Photius, by the abbé Jager, was published at Paris in 1845, and has passed through several editions.

PHOTOGRAPHY (Gr. *φως*, light, and *γραφω*, to write), the art of depicting objects by the agency of light, sometimes termed the photogenic or heliographic art. The earliest observations on the chemical changes produced by the agency of light were doubtless those of the fading and bleaching of vegetable colors. The delicate tints that may be obtained from the parts of plants are usually so unstable or fugitive, as it is termed by painters, that they are unsuitable for the purposes of permanent dyeing. Some are so sensitive to light that an exposure of only a few moments is sufficient to injure them; others resist for a longer time the conjoint action of sunlight, air, and water. The old process of bleaching, as conducted in bleachfields, was strictly a photographic operation. The cloth to be whitened was exposed on the fields to the sun, being occasionally moistened with water. Oxidation of the coloring matter it had originally contained by degrees took place, and after a certain period of time the fabric became perfectly white. It was noticed by the alchemists, probably about the 12th century, that the chloride of silver blackens by exposure to the sun, though when first prepared it is as white as snow. This darkening is in a general manner proportional to the brightness of the light. It does not occur instantaneously, but in a regulated way, a given quantity of light being apparently necessary for the production of a definite effect. As experimental chemistry was cultivated, the list of substances thus influenced became greatly extended, so that at the time when Berzelius published his work on chemistry, several scores of bodies were known to be changeable by luminous agency. Some of these were elementary bodies, and some were compounds, derived from both the inorganic and organic groups. Perhaps the first germ of photography as an art is presented in an experiment of Priestley's, who caused some chloride of silver to be deposited on the side of a glass bottle, and then putting round the bottle a piece of dark paper out of which letters had been cut with a penknife, the arrangement was exposed to the sun. All those portions of chloride upon which the light had fallen, through the spaces where the paper had been removed, turned black, but those protected by the dark paper retained their whiteness unimpaired. A sun print or sun writing was thus produced. Attention having been thus drawn to the changing appearance of chemical substances through the action of light, Scheele, a Swedish philosopher, who shares with Priestley the honor of discovering oxygen gas, made some very instructive experiments for the purpose of determining whether it is some specially colored ray of light, or light in the aggregate, that produces the result. He caused a beam to enter a darkened chamber through a hole in the window shutter, as in Newton's experiment for the decomposition of light, and, intercepting the beam by means of a glass prism, dispersed it into its constituent rays. The colored spectrum thus produced was received on a sheet of paper painted over with chloride of silver. It was thought that if the luminous agent acts in the aggregate, the blackening should commence in the yellow region, because the yellow is the brightest space, and from this toward the extreme red in one direction, and the extreme violet in the other, the darkening should gradually decline, and beyond the limits of visibility should altogether cease, the chloride retaining its whiteness. But Scheele *found* that, instead of the action being at a maximum in the yellow as he had expected, the case was altogether different. The blackening began in the indigo or violet region, and extended in the more refrangible direction, far beyond the limits of visibility. In the other direction it stopped short in the blue space, so that the green, the yellow, the orange, and the red exhibited no kind of action. From this it would appear that a sunbeam does not darken the chloride of silver in virtue of its light, but that the decomposition is brought about by some other principle contained in the beam, conjoined with the light, and found to the greatest degree in the more refrangible end of the spectrum. To the rays thus recognized as occasioning the changes the designation of chemical rays was given, to distinguish them from the proper rays of light; and as it was subsequently discovered that the chemical operation commonly accomplished by them was one answering to deoxidation, they likewise received the epithet deoxidizing rays. These experiments of Scheele gather very great interest when compared with some made by Sir William Herschel, the astronomer, on the distribution of heat in the spectrum. In observations upon the sun with reflecting telescopes, he had been obliged to use colored glass screens, for the purpose of diminishing the excessive brilliancy of the light, and had accidentally noticed that the heat transmitted through these colored glasses was very far from being proportional to the light. A glass colored deeply enough to absorb a large portion of the *light* rays, might nevertheless transmit an unexpected proportion of the heat rays. He therefore prepared a solar spectrum after the manner of Newton, and set in each of its colored spaces the bulb of a delicate thermometer, expecting, as Scheele did in the parallel case of the chemical rays, that if the brightest ray was the most effective, the thermometer in the yellow space would stand highest, and in the others in a declining way toward each end of the spectrum. But he found that this was very far from being the case. Starting from the violet and descending through the indigo, the blue, green, yellow, orange, and red, the thermometer stood higher and higher; nay, even, what was altogether unexpected, outside of the red and beyond the visible limits of the light, the thermometer stood highest of all. No other interpretation could apparently be given to such an experiment than *that* the heat and the light are altogether independent agents, and distributed very differently in the spectrum. It is to be remarked that this conclusion contained, however, a most important error, which was perpetuated until a later period in these discoveries; it overlooked the physiological peculiarities of an organ of vision like the human eye. When these peculiarities were duly considered, it was perceived that this hypothesis of the physical independence of light and heat was very far from having been established by these experiments. Count Rumford made several ingenious experiments with a view of determining the mode of action of the sunlight in producing chemical changes, and came to the conclusion that it answered very closely to that which is observed in decompositions by heat at a very high temperature. But the first attempt at applying these principles photographically, that is, for the delineation of external forms, is to be attributed to Mr. Wedgwood, who by imbuing leather with a solution of nitrate of silver, and exposing it under the images of a magic lantern slide, succeeded in obtaining what would now be termed negatives. Sir Humphry Davy made some attempts of a similar kind; but as neither of these experimenters could fix the images they had thus obtained, their results were altogether abortive. But little was done from this time in the way of a systematic examination of the phenomena of the chemical rays until about 1835, when Dr. Draper commenced publishing in the "Journal of the Franklin Institute" a series of papers on the subject. The facts investigated were chiefly in connection with the influence of light upon crystallization, the effect of colored absorbing solutions upon the chemical rays, and the interference and polarization of these rays. In these experiments, bromide of silver, and other compounds much more sensitive to light than any that had hitherto been used, were resorted to. In 1839 popular attention was suddenly directed to the subject by the announcement in France of Daguerre's invention for the fixation of the images of the camera obscura, and simultaneously in England of that of Mr. Talbot. In the former of these the material employed was a metallic tablet of silver-plated copper, in the latter paper. With these inventions the art of photography properly speaking begins.—The process of Daguerre, as divulged to the French government in consequence of a pecuniary reward given to him, is as follows. A tablet of silver-plated copper is carefully cleaned, by means of pumice, rottenstone, or other suitable powders, from all adhering impurity, and is brought to a perfectly reflecting and mirror-like surface. The success of the subsequent operations turns upon the purity and perfection of this surface. The tablet is then exposed to the vapor of iodine, rising at the ordinary temperature of the air, and in succession it passes through a series of brilliant tints in the following order: pale lemon yellow, bright yellow, orange, red, blue, steel gray, clear metallic without color; then again yellow, red, &c., in the same order. Of these tints the first and second yellow are the most sensitive to light, the others comparatively sluggish. The plate is therefore only exposed until the first full yellow is reached, and then with a careful exclusion of light it is deposited in the camera obscura, so as to receive the image. Here it remains for a period dependent on the brightness of the light, the length of which the operator learns from experience. Screened from the chance access of light, it is now removed from the camera, and if it be critically examined in a dark room by the light of a feeble taper, not the slightest change or action of any kind is perceptible upon it. Nevertheless there is an image concealed, which may be easily evoked by exposing the plate to the vapor of mercury at a temperature of about 170° F. After such an exposure for 3 or 4 minutes, the picture comes forth, the camera image being reproduced nearly in its proper order of light and shade. This accomplished, it merely remains to dip the tablet in a solution of hyposulphite of soda, which instantly removes the yellow film or tarnish upon it; and after being copiously washed in clear water, the photograph is insensible to any further action of light. In this operation of Daguerre's there are therefore several successive stages: 1, the cleaning of the plate; 2, the iodizing; 3, the exposure in the camera; 4, mercurializing or development; 5, fixing. These are terms which became of current use in the art. It does not appear in what manner Daguerre first became acquainted with the relations of the iodized film to light and the vapor of mercury respectively. Probably it was the result of some chance observation in an attempt to blacken the silver by iodine, and to whiten it by mercurial vapor. As was seen from his first publication, he was altogether unacquainted with chemistry, and spoke of the decomposition of the elementary substances he was using as if it had actually taken place. By profession he was a painter of dioramas. He had been associated previously to this successful result with M. Niepce, in an attempt to obtain photographic images by the action of light upon resins and bitumens; and though it is said that the latter had carried his operation to such perfection that etchings of camera images had been procured, and even pictures printed from them, the operation was either so tedious or so doubtful that it never came into use.—Mr. Talbot's invention of the calotype or photogenic drawing, as he termed it, consisted essentially in covering a sheet of paper with a changeable salt of silver, exposing it in the camera, and developing the latent image by a solution of gallic acid. The result was a negative; that is, a photograph in which the lights and shadows answer respectively to the shadows and lights of the original; while in a positive the lights correspond to lights, and the shadows to shadows. It had this advantage over Daguerre's, that it was capable of multiplication; for from such a negative, if applied face downward on sensitive paper, many positive copies could be successively obtained by exposure to the sun. The daguerreotype, however, had a superiority unapproached even to this day by any other process; its images were exquisitely defined and sharp, and given with microscopic minuteness. The reason of this superiority is obvious. The daguerreotype is formed on a mathematical surface; the photograph in a translucent substance, in which the light can be diffused, and therefore the contours of objects are never optically sharp.—At first photography was limited to artificial views and interiors. It was found unsuited for the reproduction of landscapes, the green color necessarily predominating, which acts on the silver salts employed in a very sluggish way. The great and really valuable extension of its capabilities was that of taking portraits from the life. This is due to Dr. Draper of the university of New York, who succeeded in it very shortly after Daguerre's process became known in America, and who published the first complete account of it in the "London, Edinburgh, and Dublin Philosophical Magazine" of the following year. To so great a degree of perfection was this branch of the art immediately carried, that it is said that some of the portraits obtained by that chemist have not been since excelled. This great improvement was accomplished at a time when the inventor of the daguerreotype himself had given it up as impracticable. Two other improvements on the daguerreotype process were soon after discovered. The first consisted in more perfectly fixing the picture and deepening its shades, by the use of a salt of gold. This was due to M. Fizeau. The second consisted in the use of a much more sensitive preparation, the bromide of silver. This diminished the time of exposure in the camera to about one thirtieth part of what was formerly required. The original process was modified in the iodizing part, the tablet being first exposed to iodine until it became yellow, then to bromine vapor arising from bromide of lime until a faint rose red was reached, and then back again to iodine vapor for a few moments. The other stages of the operation were conducted without any modification. As was shown by Dr. Draper in the paper referred to, and others subsequently published in the "Philosophical Magazine," there is no iodine disengaged from the silver plate during the period of its exposure to light. The white portions of the resulting image consist of a compound of silver and mercury, a white amalgam of silver, while the shadows or dark parts are the pure silver unchanged. In an examination of some of these papers by Sir John Herschel, an opinion was expressed that the colors displayed by a daguerreotype plate, and the peculiarity of its images, depend on the thickness of the film which has been affected; but this opinion can scarcely be correct, since it is possible to copy a daguerreotype by electrotyping copper upon it, or even drying upon it a film of isinglass. The explanation given by Dr. Draper, that it is a dotted or stippled surface, the dots consisting of an amalgam of silver, is doubtless correct. To Sir John Herschel photography is greatly indebted, both as a science and as an art. He communicated several elaborate memoirs to the royal society, which were published in its "Transactions." These not only refer to the optical and chemical details of the subject, but also extend it to the case of new compounds, particularly the coloring materials of flowers and plants.—But the greatest improvement in the art of photography is due to Mr. F. Scott Archer of England, who discovered the collodion process. Of this the advantages are so great, that the daguerreotype and calotype processes have become almost obsolete. It consists essentially in coating a clean glass plate with a solution of gun cotton in alcohol and ether, containing some soluble iodide. Very commonly the iodide of ammonium is employed. After a momentary exposure to the air, the collodion is found adhering to the glass as a delicate film, the ether and alcohol having in part evaporated. The plate is now soaked in a solution of nitrate of silver, technically called the nitrate bath, in which there must have been previously dissolved as much iodide of silver as the solution will take up. Under these circumstances the iodide of ammonium in the film becomes iodide of silver. The glass is now transferred from the bath to the camera, enclosed in a suitable screen or shield to protect it from extraneous light. The exposure is then made as in daguerreotyping, and the invisible image is developed by pouring upon the film either a solution of pyrogallic acid or of protosulphate of iron. Too great activity in these substances is prevented by the previous addition of small quantities of acetic acid. The image comes forth as a negative, and it now remains to fix it. This is done by either soaking it in hyposulphite of soda, or pouring upon it a solution of cyanide of potassium; the film is then thoroughly washed with water and suffered to dry. From this negative proofs on paper may be printed, it having been first varnished with amber varnish or some other suitable material that will not soften in the sun. But if the solutions used in its preparation have been much weaker than is necessary for the production of such a negative, and the quantity of iodide of ammonium smaller, a positive on glass may be in the first instance obtained. Various names have been given to such positives, according to the manner of mounting them. Thus if the plate of glass bearing the image be joined to another plate by means of Canada balsam, and viewed against a black surface, it is designated an ambrotype. For the production of such positives a very much shorter period of time is required in the camera than for a negative. Sometimes, through inadequate exposure to light or a want of sensitiveness in the preparations, the result obtained as a negative is not sufficiently dense, and it becomes desirable to strengthen it in order to use it for printing. Various methods have been recommended for this intensifying, as it is termed, but by far the best hitherto published is that of Dr. Henry Draper, which simply consists in applying to the collodion picture before it is dry a solution of the protochloride of palladium. This instantly produces an inky blackness in the dark parts, and affects in like manner the shades in the order of their gradation. It imparts no stain nor impurity to the proof.—The operation of printing from a negative is thus conducted. Paper of very uniform consistency is coated on one side with a thin deposit of chloride of silver, conveniently produced by soaking the paper in chloride of ammonium or chloride of sodium, and then laying it on the surface of a solution of nitrate of silver. Thus prepared, the paper is placed beneath a varnished negative, and exposed to the sun. The light transmitted through the glass in its transparent parts produces blackness in the paper, but those places corresponding to the black portions of the negative remain white in the proof, the intermediate shades being of course intermediately affected. When the change has taken place to a sufficient extent, the paper is removed from beneath the negative and soaked in a solution of hyposulphite of soda. This dissolves out all the unaffected chloride of silver, and leaves the picture without any liability to further change. But as the tone or tint of color that it presents is commonly regarded as unpleasing to the eye, it is laid in a bath containing chloride of gold, which after a while imparts to it a delicate violet hue. Toning baths, as they are termed, of various ingredients, and capable of imparting shades of a sepia and brown tint, are recommended by different operators. They are too numerous to be here described.—The following formulas for the collodion process have been recommended: 1. For the collodion: gun cotton, 4 to 8 grains; sulphuric ether, sp. gr. .720, 5 fluid drachms; alcohol, sp. gr. .825, 3 fluid drachms; iodide of ammonium, 4 to 5 grains. 2. For the nitrate bath: water, 1 fluid ounce; nitrate of silver, 30 grains; as much iodide of silver as it will dissolve. 3. For the developer: water, 1 fluid ounce; pyrogallic acid, 1 grain; acetic acid, 10 to 20 minims. 4. Or this: water, 1 fluid ounce; protosulphate of iron, 12 to 20 grains; acetic acid, 20 minims. 5. For the fixing solution: water, 1 fluid ounce; cyanide of potassium, 2 to 20 grains. 6. For the fixing solution (another formula): water, 1 fluid ounce; hyposulphite of soda, ¼ ounce. The following formulas may be useful in the printing process: 7. For the salting solution: chloride of ammonium, 200 grains; water, 10 ounces. 8. For the sensitizing solution: nitrate of silver, 60 grains; water, 1 fluid ounce. 9. For the fixing solution: hyposulphite of soda, 4 ounces; water, 8 ounces. 10. For the toning solution: chloride of gold, 4 grains; hyposulphite of soda, 4 ounces; water, 8 ounces. If the paper previously to being sensitized has been imbued with albumen, the resulting proofs (albumen proofs, as they are termed) have a glossy and much improved appearance. It is of course to be understood that a print as well as the original collodion must be thoroughly washed in clear water after the process for fixing or toning has been completed; otherwise it will be liable to a spontaneous fading away.—Among the recent applications of photography must not be omitted the interesting one of the stereoscope. Stereoscopic photographs may either be made by a purposely constructed camera with a pair of lenses, or by a single camera set successively in two different determinate positions. The illusion of the stereoscope gathers force from the truth of the photograph, and such pictures, from the air of solidity that they present, give a very striking result, not only in the case of portraits from the life, but also in landscapes, and especially in architectural objects.—Though photographs as now produced by the best artists are of very great beauty, they are nevertheless very imperfect. They do not critically represent the exact order of light and shade; and what is a still greater defect, they do not represent the order of luminosity, as dependent upon the coloration of the object. To the eye the yellow is the brightest color, the intensity of the light declining as we go to the violet end of the spectrum on one side, and to the red on the other. But in all the silver preparations in use among photographers, the indigo ray produces the greatest effect, and therefore may be said to possess the greatest illuminating power, and from it the intensity declines toward the violet on one side, and ceases on the other before the yellow is reached. The effect of this in a photograph may be easily understood. If two pieces of paper, one painted light yellow and the other deep indigo, be examined by the eye, the former impresses us most vigorously, and we speak of it as being bright in comparison with the other. But if a photograph of these two pieces of paper be taken, the deep indigo will come out white, and the light yellow completely black. So the real order of their visual intensity is reversed in their photographic representation. It is for this reason that thus far photography has given such unsatisfactory results in its application to the delineation of landscapes.—Nothing would tend so quickly to the improvement of photography as the invention of some means for the accurate admeasurement of light; *i. e.*, some instrument that would answer for the luminous agent, as the thermometer answers for heat. Thus far the contrivances that have been recommended imply the conducting of an experiment rather than the making of an observation. Though they may answer well enough in the hands of an accomplished chemist, they are unsuitable for the common operator. Among them may be mentioned the galvano-photometer of M. Becquerel, and the chlorine and hydrogen photometer of Dr. Draper.—Owing to the want of durability of photographs obtained by the aid of salts of silver, attempts have been made to substitute for those compounds others not liable to change. Among such may be classed carbon, which is altogether unalterable in the air. But the carbon process, though not without merit, is very far from having reached a degree of perfection that would bring it into competition with the older methods.—From what has been said respecting visual impressions and photographic representations, it will be perceived that the agent which accomplishes the latter is not light, and that therefore the term photography is in truth a misnomer. Among those chemists who have examined the scientific connections of this subject, differences of opinion have prevailed respecting the relation between the principle thus involved and the luminous and calorific agencies. These differences of opinion have led to different designations for the rays darkening the silver preparations. Some of the earlier experimenters spoke of them as deoxidizing rays, some as chemical rays; others, in allusion to their position at the more refrangible end of the spectrum, as violet rays; others as tithonic rays; but the term that has met with most general acceptance is actinism or actinic rays (Gr. *ακτιν*, a sunbeam). This designation must however be considered as very inexpressive, and therefore ill chosen. On the undulatory theory of light, all these discussions and designations are needless. The essential difference in the colors of light lies in the differences of their wave lengths. The red, orange, yellow, green, blue, indigo, and violet arise from undulations that are smaller and smaller in the order of the colors as they are here named, and in such a proportion that the wave length of the first red light that the eye can perceive is exactly twice that of the last violet. The most brilliant part of the yellow stands intermediately between these limits, and has therefore a proportionate wave length of one and a half. From these facts it therefore follows, that waves of heat are greatest in their length and slowest in their time of vibration, and that as we ascend in succession through the visible spectrum, from its less to its more refrangible end, the wave length is diminishing, the rapidity of vibration increasing. The cause of any chemical decomposition by a ray is that the parts of the changing substance are thrown into movement by the impinging vibrations; and so long as those vibrations are too slow, the movement and therefore the decomposition cannot take place. But a certain rate of speed being reached, motion occurs and decomposition ensues, just as a stretched string may be made to vibrate sympathetically by a sound in unison with it. These explanations, though not so easily understood as those founded on the theory of the emission of light, possess a scientific advantage. The undulatory theory does not require an admission of many different coexisting principles, but accounts for all the facts by differences of movement in one homogeneous and universal ether.—From what has been said respecting the distribution of chemical rays in the solar spectrum, it will be understood that optical instruments for photographic purposes must be of the most perfect kind, and provided with the necessary means for depicting a perfect image of the objects to which they are directed. They must therefore be not only achromatic in the common acceptation of that term, but also achromatic photographically, and likewise have adequate provisions against spherical aberration.—The applications of photography have been so numerous, that it is now followed as an industrial pursuit in the United States and other countries by many thousands of persons. It also possesses a very extensive literature, from the highest scientific investigations, inserted in the transactions of various learned societies and special treatises in many instances of considerable size, to periodicals weekly, monthly, quarterly, and annual. Beside those who practise it professionally, it finds amateurs everywhere, sometimes among the most eminent personages. There is so much activity among its cultivators, that in the United States, England, France, and Germany, photographical societies are well sustained in many of the large towns. The general popularity which photography has thus attained is founded not only upon the realized perfection with which it can perpetuate external forms, but also upon the anticipated advantages hereafter to accrue from it in several of the higher departments of science. Already its application as a register of celestial phenomena indicates the benefits which it will result to astronomy. It has been employed for the purpose of permanently recording the aspect of the moon and the eclipses of the sun, and it only needs the use of some more sensitive material to enable it to give us representations of the planets, and even the configuration of the stars. To the microscope it has likewise been successfully applied, fixing the enormously magnified images presented by this instrument with a perfection and beauty altogether unattainable by the hand of man. In this manner questions of the utmost importance in physiology and the sciences of organization, which have long been in dispute, have received a final solution, and permanent representations have been obtained of transient phenomena occurring in living organisms. In meteorology likewise, a coil of sensitive paper receiving the shadow of the mercury in the thermometer or in the barometer, or of the suspended magnetic needle, or of the index of the wind gauge, supplies the place of an ever watchful observer, and gives us trustworthy records of the temperature and pressure of the air, of the variations in terrestrial magnetism, and of the motions of the atmosphere. But perhaps of all the sciences, botany is destined to be most dependent for its advances on discoveries connected with the chemical influences of light. The very growth of plants is determined by the yellow rays, and, as was proved by Dr. Gardner, their movements by the indigo rays. It is through the power of these that leaves and flowers offer themselves in a determinate direction toward the solar beams, bending round obstacles to present themselves most favorably to the light. Each of the colored and indeed each of the invisible rays seems to discharge a definite duty in the economy of plants.—On the fine arts the effect of photography has been important, and every day is increasing the number of its applications to artistic purposes. Soon after the discovery of the collodion process the facilities afforded by it for the multiplication of copies attracted the attention of publishers. Mr. G. P. Putnam of New York was the first to introduce it practically by the insertion of some photographic views in the "Homes of American Authors" (New York, 1854). In France and Germany many splendid books have been illustrated by the same method, as the superb memorial edition of Schiller now publishing with photographs from the original drawings of eminent living artists of Germany. For the representation of scenery or the copying of old paintings, drawings, &c., it is equally available; brilliant and well known specimens of its powers in those departments are Frith's "Scenery of Egypt and Palestine," Fenton's "Views in the Crimea," Raphael's cartoons, Rembrandt's etchings entirely reproduced by photography at Paris, &c. Its latest uses are for archæological purposes. The most ancient Greek MS. of the New Testament, discovered at Mount Sinai by Tischendorf, is now being photographed in 4 large volumes folio, at the expense of the emperor of Russia; and the British government is perpetuating by the same process the great Anglo-Norman record, the "Domesday Book." On the art of painting, the unlimited supply of photographic studies, combining breadth of effect with nature's own minuteness of detail, is producing the most marked results; while, should the progress of photography keep pace with its past achievements, many of the laborious and expensive enterprises of engraving on steel and copper will soon be entirely superseded. For instance, the publication of Kaulbach's illustrations of Shakespeare, begun in copperplate engravings (Berlin, 1856), is now continued in photographs.

PHOTOMETER. See Light, vol. x. p. 517, and Photography, vol. xiii. p. 290.

PHRENOLOGY (Gr. φρήν, mind, and λόγος, discourse), a system of philosophy of the human mind, founded on the physiology of the brain. As a system, it has its origin in the ideas and researches of Franz Joseph Gall, a German physician. First announced by him in 1796, it began to attract attention in England about the year 1815. It was first distinctly introduced into the United States through the labors of Dr. Charles Caldwell of Kentucky, who studied under Gall in Paris about 1820, and who, between 1821 and 1832, wrote and lectured on the subject, forming phrenological societies in New York, Philadelphia, and other large cities. The number of its adherents was small, however, and these mainly of the medical profession, until the period of Dr. Spurzheim's lectures, chiefly in Boston, in 1832, and the commencement of a series of lectures and cranioscopic examinations by the brothers O. S. and L. N. Fowler, in 1834. The lectures of Mr. George Combe in 1838–'40, in various cities from Boston to Washington, contributed much to the general and favorable introduction of the new system; and still more the "Constitution of Man" and other well known works of the brothers Combe. Since that period the number of the advocates of phrenology appears to have been greatly increased, though many of its principles, both theoretical and practical, are still under discussion.—Phrenology aims to be neither simply a science of mind nor a theory of the functions of the brain, but a system including the elements of both mind and brain, with their relations, and with consequent applications in respect to the development of the mental faculties, to the conduct of the individual and social life, to education, legislation, the arts, morals, and religion. Hence, its subject matter embraces, first, a theory of psychology, and secondly, an organology, or view of the relations of cerebral parts or organs to the mental faculties; this, again, being divisible into organology proper, and physiognomy in the broadest sense, or the knowing of the mental characteristics through signs, including cranioscopy (signs learned by examination of the cranium), temperaments, the features, and attitudes. It assumes that the value of all these, as signs of character, is based on a necessary correspondence, for every individual, first, between mind and brain, and secondly, between the brain on one hand, and other parts of the physical organization, as well as the habits and conduct, on the other. The belief in a plurality of mental faculties has been the rule in the various schemes of mental philosophy that have been proposed, though the number and nature of the faculties assumed have varied greatly. Again, our own consciousness, as well as observation, indicates the brain as the seat of the thinking principle; and while the intellect had usually been located in this organ, the sentiments and passions were more commonly, up to the time of Gall, supposed to reside in certain viscera, as the heart, liver, spleen, &c. Albertus Magnus, in the 13th century, divided the cranium into 3 regions, appropriating these, from before backward, to the Aristotelian faculties, judgment, imagination, and memory. Ludovico Dolce, in a work on the memory (Venice, 1562), drew a chart of 9 regions of the brain, answering to as many mental powers. Willis, and in 1784 Prochaska, especially advocated the doctrine of a division of the brain into organs of different mental faculties, though they did not attempt to localize such organs. The extreme diversity of natural talents early impressed the mind of Gall. His first special observation seems to have been that of a prominence of the eyes in all his schoolfellows who were noted for linguistic proficiency and memory of words. Following out the hints thus obtained, he arrived ultimately, as he believed, at the function and location of 27 organs of mental faculties, which he naturally enough named in view of their action, or in many instances of the extravagant and perverted action under which, in their extreme development, he often found them; hence, such terms as instinct of murder, vanity, &c. Of these all but one were retained by his pupil Spurzheim, who found reasons for including in one the two supposed powers of language; and who then added to the remaining number, first, by distinguishing in Gall's faculty of the "sense of things" the two powers of individuality and eventuality; and secondly, by discovering the office and seat of conscientiousness, hope, wonder, size, weight, time, order, and inhabitiveness. In Mr. G. Combe's enumeration, the last named faculty was replaced by concentrativeness; and he added the localities of love of life and alimentiveness, the probable existence of which had been admitted by Spurzheim. The latter set the example of naming the faculties with reference to their tranquil manifestation and supposed normal character; and in following out this principle he introduced an almost entirely new terminology. The names and order adopted by each of these writers appear in the subjoined tables; the figures following names in the second refer to the corresponding faculties in the first:

NOMENCLATURE OF GALL (translated).

1. Instinct of procreation.
2. Love of young, love of offspring.
3. Attachment, friendship.
4. Courage, quarrelsomeness.
5. Carnivorous instinct, murder.
6. Deceit, cunning, tact.
7. Sense of right of property.
8. Haughtiness, pride, *hauteur*.
9. Vanity, ambition, love of glory.
10. Cautiousness, foresight, circumspection.
11. Sense of things, educability, perfectibility.
12. Sense of place, sense of space.
13. Sense of persons.
14. Sense of words, sense of names.
15. Sense of relations of words.
16. Sense of colors.
17. Sense of tune.
18. Sense of relations of numbers.
19. Sense of mechanism, sense of building.
20. Sagacity in comparison.
21. Metaphysical talent, penetration.
22. Wit.
23. Poetic talent.
24. Good nature, compassion, benevolence.
25. Ability to imitate, mimicry.
26. Religious sentiment.
27. Firmness, constancy, perseverance.

[illegible] NOMENCLATURE OF SPURZHEIM.

I. PROPENSITIES.
1. Destructiveness (5)
2. Amativeness (1)
3. Philoprogenitiveness (2)
4. Adhesiveness (3)
5. Inhabitiveness.
6. Combativeness (4)
7. Secretiveness (6)
8. Acquisitiveness (7)
9. Constructiveness (19)

II. SENTIMENTS.
10. Cautiousness (10)
11. Approbativeness (9)
12. Self-esteem (8)
13. Benevolence (24)
14. Reverence (26)
15. Firmness (27)
16. Conscientiousness.
17. Hope.
18. Marvellousness.
19. Ideality (23)
20. Mirthfulness (22)
21. Imitation (25)

III. INTELLECTUAL FACULTIES.
(1.) *Perceptive.*
22. Individuality (11)
23. Form (13)
24. Size.
25. Weight.
26. Color. (16)
27. Locality. (12)
28. Order.
29. Calculation. (18)
30. Eventuality. (11)
31. Time.
32. Tune. (17)
33. Language. (14, 15)

(2.) *Reflective.*
34. Comparison. (20)
35. Causality. (21)

Probable Faculties.
Desire to live.
Alimentiveness.

The arrangement adopted in Combe's "System of Phrenology" (4th ed., Edinburgh 1836) is substantially as follows:

ORDER I. FEELINGS.

GENUS I. PROPENSITIES: 1, amativeness; 2, philoprogenitiveness; 3, concentrativeness; 4, adhesiveness; 5, combativeness; 6, destructiveness; alimentiveness; love of life; 7, secretiveness; 8, acquisitiveness; 9, constructiveness.

GENUS II. SENTIMENTS. (1.) Sentiments common to man and the lower animals: 10, self-esteem; 11, love of approbation; 12, cautiousness. (2.) Superior sentiments: 13, benevolence; 14, veneration; 15, firmness; 16, conscientiousness; 17, hope; 18, wonder; 19, ideality; 20, mirthfulness; 21, imitation.

ORDER II. INTELLECTUAL FACULTIES.

GENUS I. THE EXTERNAL SENSES.

GENUS II. PERCEPTIVE FACULTIES, noting existence of objects [omitted from 2d edition]: 22, individuality; 23, form; 24, size; 25, weight; 26, coloring.

GENUS III. PERCEPTIVE FACULTIES, noting obvious relations of objects: 27, locality; 28, number; 29, order; 30, eventuality; 31, time; 32, tune; 33, language.

GENUS IV. REFLECTIVE FACULTIES: 34, comparison; 35, causality.

Dr. Vimont, Robert Cox, J. T. Smith, and other trans-Atlantic writers, have criticized portions of both the scheme of faculties and the location of organs, and have proposed greater or less changes. The brothers Fowler admit still other faculties, increasing the number to 43; and they have changed again several of the names. The following is their most recent classification (1860) of the faculties and organs which they regard as ascertained (the definitions, for the sake of condensation, being slightly modified in some instances), the whole arranged in 4 groups of affective and 2 of intellectual faculties, as follows:

DIVISION I. AFFECTIVE FACULTIES.

(1.) DOMESTIC GROUP: 1, amativeness—the sexual instinct, or impulse; A, conjugality—the pairing instinct, exclusive love of one; 2, parental love—love of offspring, love of young, or of pets; 3, friendship—the gregarious or social impulse, attachment to friends; 4, inhabitiveness—love of home and country, desire to locate, patriotism; 5, continuity—persistence of emotion or of thought, application, absorption in one thing.

(2.) SELFISH GROUP: E, vitativeness—love and tenacity of life, dread of annihilation; 6, combativeness—impulse to resist and oppose, resoluteness, courage; 7, destructiveness—readiness to inflict pain, to destroy, or to exterminate, executiveness; 8, alimentiveness—appetite for food; F, bibativeness—fondness for water or other beverages; 9, acquisitiveness—desire to possess and own, impulse of getting and hoarding; 10, secretiveness—instinct of reserve and evasion, cunning, policy; 11, cautiousness—sense of danger or evil, desire of safety, watchfulness; 12, approbativeness—love of approval or of praise, love of display, sense of reputation, ambition; 13, self-esteem—sense of self-appreciation and self-respect, dignity, pride; 14, firmness—constancy of will and purpose, perseverance.

(3.) MORAL GROUP: 15, conscientiousness—sense of right and truth, feeling of justice and obligation, integrity; 16, hope—sense of and happiness in future good, anticipation; 17, spirituality—sense of the unseen, faith [love of the marvellous, credulity]; 18, veneration—sense of Deity, adoration, worship; 19, benevolence—desire of human well-being, love of others, self-sacrifice.

(4.) SELF-PERFECTING GROUP: 20, constructiveness—instinct of building, ability to combine or construct [synthesis?]; 21, ideality—sense of the beautiful and perfect, of the pure and elegant, imagination (?); B, sublimity—love of the vast and grand, sense of the infinite; 22, imitation—ability to pattern after, copy, or imitate; 23, mirthfulness—sense of the absurd or ridiculous, wit, humor.

DIVISION II. INTELLECTUAL FACULTIES.

(1.) PERCEPTIVE GROUP: 24, individuality—perception of things or individual objects, curiosity to see; 25, form—perception of shape, or configuration, including features; 26, size—perception of dimension or magnitude, and quantity generally, sense of space; 27, weight—perception of effort or pressure, of force and resistance, of gravity and equilibrium; 28, color—perception of hues, tints, lights and shades; 29, order—cognizance of arrangement, method, system; 30, calculation—cognizance of numbers, and their obvious relations; 31, locality—cognizance of place, and of situation; 32, eventuality—cognizance of events, occurrences, or facts; 33, time—cognizance of succession and duration; 34, tune—cognizance of melody and harmony; 35, language—cognizance and use of all signs of thought and feeling, words included, power of expression.

(2.) REFLECTIVE GROUP: 36, causality—cognizance of dependence, and of efficiency, or the relation of effect to cause; 37, comparison—cognizance of resemblances, of identity and difference, discriminating, power of analysis and of criticism; C, human nature—discernment of character and motive; D, agreeableness—suavity, ability to conform, and to be in sympathy with those about one.

It is not pretended that either the analysis or classification of the mental faculties has yet been satisfactorily accomplished. Dr. Caldwell appears not to have introduced any important changes into the classification or naming of the cerebral organs. Dr. J. R. Buchanan of Cincinnati has taught since 1842 a "System of Anthropology" (published at Cincinnati in 1854), which departs in many particulars from the received system; especially in subdividing the brain and increasing the number of faculties to a much greater extent, and in recognizing and claiming to localize, by the aid of certain assumed principles of impressibility, and chiefly in the under surfaces of the brain, faculties antagonistic to nearly or quite all those which may be termed the useful or noble—thus admitting regions of vice and crime, as well as of virtue and excellence, and supposing such positive elements of mind as hatred, antagonizing love; baseness, integrity; sensibility, hardihood; coarseness, ideality; servility, pride, &c. Dr. W. B. Powell, of Kentucky, has also proposed certain modifications of the scheme, claiming, among other things, to have established a threefold division in the cerebellum and its functions, namely, into: 1, a faculty of motion, including impulse to and regulation of muscular movements (a function specially insisted on by physiologists); 2, amativeness, as impulse merely; 3, the sensuous element or feeling, active in touch and in caressing. Dr. Carus, of Dresden, has published a "New Cranioscopy" (Stuttgart, 1841), in which he divides the brain into a small number of regions, rather than into organs. Mr. John S. Hittell has published (New York, 1857) a system of phrenology, which differs from that commonly received, chiefly in the rejection of such faculties as form, color, imitation, hope, acquisitiveness, &c., 17 in all, and many of which must be regarded as among the most clearly established in the catalogue. Among those in the United States who have become known for the advocacy or the popularizing of phrenological principles, should also be mentioned Mr. J. S. Grimes, Mr. D. P. Butler, Mr. Nelson Sizer, and Dr. Levi Reuben, the last of whom contends that, in a combination of the fruits of metaphysical study, furnishing as it were the physiology of mind, with a true scheme of elements, or anatomy of mind, phrenology can alone become a complete and satisfactory body of mental science.—Many of the received phrenological elements are allowed or anticipated by certain of the metaphysical writers; though, in respect of others, they diverge widely. As now developed, phrenology presents these leading priciples: 1, mind and body are in this life inseparable, a concrete *ego*, and must be investigated together; 2, the brain is the immediate organ of the mind, all the operations of the latter arising along with changes in the substance of the former; 3, the brain is a double organ, the halves of which can act singly, but usually do act together; 4, there are individually distinct mental elements, but bound together in a unitary consciousness, which recognizes all as of itself; 5, power of mind, or of any faculty, other things being equal, will be as the size of the brain, or of the corresponding organ; while among those other things, quality of organization and temperament, as well as states of health and disease, are of great importance. Among the leading proofs of the system are adduced the successive manifestations of inherent abilities in the same mind; the diversities of natural talents; the variety, partiality, and transmissibility of genius; and the phenomena of dreaming, of partial idiocy, monomania, and diseases and injuries of the head and brain. Whether the localities of the faculties in the brain have been properly found, is still an undecided question, especially in view of such facts as that, first, while we descend in the scale of vertebrates, it is the human, the moral and intellectual powers, that rapidly disappear, while at the same time the anterior lobes of the cerebrum remain until the last, and the posterior and then the middle lobes are the first to shrink and be obliterated; and secondly, no distinct separation of organs in the cerebral hemispheres, corresponding to the prominences on the cranium, have yet been made out. It is asserted, however, that strong confirmation of the Gallian system is found in the examination of crania of noted characters and of criminals, as well as of the skulls of animals; and extensive collections of these and other specimens have been made. That of Dr. Gall contained of human crania, &c., 354; the Edinburgh museum has 463 natural specimens, and 380 artificial, the former including crania of various nations. Mr. Deville of London accumulated 5,450 pieces, 2,450 human specimens, and 3,000 crania of animals; among the former were many of persons of marked peculiarity of character. (Edinburgh "Phrenological Journal," vol. xiv. p. 32.) The remark last made applies also to the collection of Messrs. Fowler and Wells of New York, which, though it has contributed largely to similar cabinets in Boston and Philadelphia, still numbers about 4,000 pieces, including about 300 human skulls, 200 of animals, 500 casts or busts, and 8,000 portraits and drawings. Dr. Vimont of Paris accompanied his memoir for the French institute (1827), among other specimens, with 2,500 crania of animals, of 1,500 of which he had studied the habits. Dr. S. G. Morton of Philadelphia had collected in 1841 above 1,000 crania, more than one half of which were human, of many nations, and supplying mainly the materials for his craniological works. Dr. Thomas Laycock has attempted to answer the question necessarily arising as to the mode of interaction of the faculties through the cerebral organs, by arguing that all nervous action, including the functions of the brain, is automatic. In its application, phrenology professes to find its ultimate results in a doctrine of psychology, and an art of reading character. Supposing the faculties chosen and the organs placed aright, the difficulties arising from unequal thickness of bones of the cranium, from unequal size of the frontal sinuses, &c., are minor and partial, though they must introduce a measure of uncertainty into the judgment obtained. Respecting the question of the tendency of phrenology to materialism, its advocates are divided; though the opinion that mind, as an organizing force, dominates in reality over the material conditions expressing it, has its firm supporters. But the system, if completely established, will, it is contended, carry with it a new educational, social, political, and theological science.

PHRYGIA, in ancient geography, a province of Asia Minor, whose boundaries varied materially in different stages of its history. Under the first Roman emperors it was bounded N. by Bithynia, E. by Galatia and Cappadocia, S. by Lycaonia, Pisidia, and Lycia, and W. by Caria, Lydia, and Mysia. In the 4th century the Romans divided it into two provinces, calling the eastern portion Phrygia Salutaris and the western Phrygia Pacatiana. Before the invasion of Asia Minor by the Gauls it extended as far E. as the river Halys. Most of the larger cities were situated in the S. W. part of the province; the most important were Celænæ at the source of the Mæander, famed for the mythical contest between Apollo and Marsyas; Apamea Cibotus, founded by Antiochus Soter; Colossæ, where a Christian church was established, to which St. Paul addressed an epistle; Laodicea, the seat of another Christian church; Hierapolis, renowned for its mineral springs; and nearer the centre of the province was Docimeum, the marble of which was in high repute. The principal rivers were the Mæander in the W. and the Sangarius on the

N. boundary. The country is a high table-land, the soil in the N. and W. being fertile, but covered with salt marshes and lakes in the S.—The Phrygians were regarded as one of the most ancient nations of Asia Minor, the most contradictory opinions existing in reference to their origin. By some they were considered as Thracians, by others as Armenians. In early times they seem to have been governed by kings of their own. They were conquered by Crœsus, king of Lydia, and along with the rest of his dominions became a part of the Persian empire, in which it was included in the third satrapy. After the overthrow of that empire by Alexander, Phrygia fell into the hands of Antigonus, and after his death it formed a portion of the Syrian empire founded by Seleucus. Afterward the territories of Phrygia were circumscribed by the formation of Galatia and the extension westward of Lycaonia. When Antiochus the Great was defeated by the Romans at Magnesia in 190 B. C., Phrygia was given to Eumenes II. of Pergamus. In 133 B. C. it fell into the hands of the Romans, and, with the exception of a few years when it belonged to Pontus, remained a part of their empire. It now forms a part of the Turkish empire.—A country called Lesser Phrygia is described by the ancients; and although its boundaries are not distinctly defined, it seems to have extended along the Hellespont, and to have been included in Mysia.

PHRYNE, an Athenian *hetaira* or courtesan, of the latter part of the 4th century B. C., born in Thespiæ, Bœotia. She was of low origin, and originally gained a livelihood by gathering capers; but she found the traffic in her charms more profitable, and by this means acquired so much wealth that, after Alexander destroyed the walls of Thebes, she offered to rebuild them, if she could be permitted to put up the following inscription: "Alexander destroyed them, but Phryne the courtesan rebuilt them." Among her lovers were some of the most distinguished men of the age of Alexander. When she was accused of atheism, the orator Hyperides secured her acquittal by unveiling her bosom before the assembly. Praxiteles modelled from her the Cnidian Venus, and the picture of Apelles called "Venus Anadyomene" is said to have been taken from Phryne. She once wagered that she could subdue the virtue of Xenocrates, but failing in the attempt declared that he was not a man but a statue. She had lovers late in life, as it was deemed an honor for any one to bear that title.

PHYLACTERY (Gr. φυλακτήριον, from φυλάσσειν, to guard), a name given to any amulet or charm worn by the ancients to guard them against danger and disease, or, as among the Hebrews, against transgression. Among the latter it was a strip of parchment, upon which were written passages from the Scriptures, and which, folded up and placed in a small leather box, was worn by the devout principally on the forehead. As used among the modern Jews, they are attached to the head, to the arm, and to the door posts. Very fine vellum is employed, and the writing traced with great care, while the case in which they are enclosed is made of several layers of parchment or of black calfskin. According to Lightfoot, the Saviour did not condemn the wearing of phylacteries, but the widening of them so as to gain a reputation for piety.—Among the early Christians, a phylactery was often used as an amulet, a practice forbidden by the council of Laodicea.

PHYSICAL GEOGRAPHY, that department of the science of geography which treats of the physical condition of the earth, describing its character and relations as one of the members of the solar system, explaining its great natural divisions of land and water, the atmosphere which covers them all, and the great movements, as of oceanic and aërial currents, which are ever going on, variously affecting and modifying these features. The forms of continents and oceans and of all their subdivisions, the heights and ranges of mountains, the phenomena of deserts and plains, and all the varying outlines from the highest mountain summits to the lowest depths of the sea, are among the first objects of its consideration. The geological structure of the earth and the meteorological phenomena of rain, fog, dew, hail, frost, &c., belong to the broad field of its investigations; which moreover comprises the natural products of the earth, vegetable and animal. But wide and comprehensive as is the range of this science, it enters not into individual descriptions of phenomena, localities, and species, but is concerned chiefly with general laws and principles, as they are manifested upon a grand scale, and in the organic kingdom with the existence of races and their distribution in certain zones of habitation or stations. The relations and adaptations of organic and inorganic nature to each other are specially treated in this science alone. Its ultimate aim, as stated by Humboldt in his *Kosmos*, the work which first gave to physical geography a place among the sciences, "is to recognize unity in the vast diversity of phenomena, and by the exercise of thought and the combination of observations to discern the constancy of phenomena in the midst of apparent changes."—The first writers on physical geography were among the earliest geographers and writers on physical science, referred to in the articles EARTH and GEOLOGY. The broad views advanced by Aristotle, Strabo, Pythagoras, and others of the ancient philosophers, entitle them to be regarded as the first cultivators of this science. In modern times its principles were treated with great originality and ability by the Jesuit José de Acosta, in his *Historia natural de las Indias* (1590). In 1650 was published the first edition of the work of Varenius, entitled *Geographia Generalis, in qua Affectiones Generales Telluris explicantur*, which, Humboldt says, "in the true sense of the words, is a physical description of the earth." A part of this the author styled *Geographia Comparativa*, which is the term now generally applied to works on physical geography; and the leading subjects discussed by him are those of the most recent treatises. The great advance made of late years in the auxiliary sciences furnished materials for more extended generalizations and a more complete "delineation of comparative geography, which was drawn to its full extent, and in all its relations with the history of man, by the skilful hand of Carl Ritter" in his *Erdkunde im Verhältniss zur Natur und zur Geschichte des Menschen, oder allgemeine vergleichende Geographie* ("Geography in relation to Nature and the History of Man, or general Comparative Geography"). The principles of the science were ably illustrated in the "Physical Atlas" of Alexander Keith Johnston, first published in 1848; and they have been expounded in the writings of Sir John Herschel, Mrs. Somerville, Arnold Guyot, and numerous other physicists, some of the most valuable contributions of whom came from those devoted to one or a few special departments of the science, as geology, meteorology, &c., and also from the most distinguished among modern travellers and explorers. In this cyclopædia the topics connected with this science are treated under their own separate heads, as CLOUDS, DEW, HAIL, HURRICANE, MOUNTAINS, as also under the more general heads of EARTH, GEOLOGY, METEOROLOGY, &c.

PHYSICIAN AND SURGEON. In all rude nations priests are the physicians, and this was the case among the Egyptians and Greeks, as it is now among the American Indians. In Greece, however, medicine early rose to the rank of a distinct science, and its practitioners were highly honored and well remunerated, although there appears to have been an inferior body of practitioners, the slaves of physicians, who practised on men of their own degree. In the earlier days of Rome, medicine, like all the liberal arts, was despised, and its practice was confined to slaves and persons of inferior station; and it was only after Grecian arts and letters were cultivated at Rome that physicians obtained a more honorable standing. The first Cæsar gave medical men practising at Rome the honors of citizenship. Augustus, having been cured of a dangerous illness by Antonius Musa, raised him to the rank of *eques* or knight, and in his honor exempted physicians in future from taxation. The Roman armies during the empire were attended by regular surgeons, and many of the stamps with which they sealed their preparations have been found in England and on the continent. While the science of medicine was thus rising in honor and importance, it was long before any guaranty that a physician was competent to exercise his profession was required by law. It was under the Christian emperors probably that physicians were first required to undergo an examination by competent persons before they were permitted to practise. There were two kinds of archiaters; the first were attached to the household of the emperor, while the second formed in every city a kind of college charged with the care of the public health. They examined all who desired to practise, and licensed them if competent; if any practised without such license, they were heavily fined. These archiaters were paid by the state and attended the poor gratuitously. Under the Christian emperors too, about the year 400, we first find mention of a class similar to our apothecaries. Previously physicians either prepared their medicaments themselves, or had them prepared by their pupils or servants.—In the general barbarism following the fall of the Roman empire, medicine as a science was completely lost, and the estimation and rewards of those who practised it must have depended upon their own good fortune and the rank of their patients. Internal medicine gradually came to be practised exclusively by the clergy; and, as they were forbidden to shed blood, operative surgery fell into the hands of an inferior class. In this manner rose the fraternity of barber surgeons. Still in France a small number of lay surgeons, under the title of the surgical college of St. Cosmas and St. Damian, carried on an obstinate struggle on the one hand with the faculty of medicine and on the other with the barber surgeons and the bone setters. During the middle ages indeed the general practice of surgery was reduced to the lowest ebb. In Germany, according to Sprengel, no artisan took a young man as apprentice without an attestation that he was born in marriage of honest parents, and came of a family in which were found neither barbers, bathers, nor skinners; yet these last were the only surgeons of most of the German towns. Very gradually a better state of things arose in the large cities, the barber surgeons acquiring knowledge and skill in the school of experience. The progress of anatomy had its influence on surgery. In 1515 the college of St. Cosmas was united with the university, and thenceforth the barbers before they could exercise surgery were examined by a physician and two surgeons of the king. Thus gradually the contempt with which they were regarded gave way before their increased attainments and their importance to the community. In France medicine, after having long been separated from surgery, was reunited to it in 1795, upon the reorganization of the medical schools. In England, on the other hand, the surgeons, incorporated with the barbers in the time of Henry VIII., only received a separate charter in 1745, and the two colleges of physicians and surgeons remain perfectly distinct. Most of the universities however throughout the world, like the Paris school, give a common degree of doctor of medicine and surgery.

—In undertaking the treatment of a patient, the physician enters into a legal obligation and assumes legal liabilities, which, though seldom expressly defined, are yet, in the apprehension of the law, fixed and certain. The law holds that he contracts for the possession of that reasonable degree of learning, skill, and experience which the members of his profession ordinarily possess. Those also who, like oculists, aurists, or dentists, claim to be particularly conversant with and skilful in the treatment of the diseases of single organs, must be held to a peculiar responsibility. The same is true of physicians of great pretensions in large cities as compared with those residing in remote and thinly settled districts. In undertaking a case, the physician also contracts that he will apply the skill which he possesses, whatever be its degree, with reasonable and ordinary diligence and care. Extraordinary care is no more implied than extraordinary skill; nor is the practitioner supposed to guarantee a cure, though he may if he chooses contract to effect a cure, and then he must answer for a failure. The physician's skill in a given case will ordinarily be required to embrace those phases and phenomena which usually characterize the dominant disease; and any mischance which connects itself immediately with these will involve the question of skill. His diligence and care will be exercised in watching for and guarding against the numerous accidental influences which, if overlooked, may delay or even prevent the restoration of the patient, such as latent predispositions to certain diseases; a lack of vital or recuperative power in the patient; the effects of melancholy and of other passions of the mind; the effect of the want of pure air and good food, of careful attendance and nursing; the neglect of the patient to follow the physician's advice or to take the medicines which he prescribes. If he have brought ordinary skill and care to the treatment of his case, the physician is not responsible for want of success nor for mistakes in cases of real doubt and uncertainty. The same is probably true of errors of judgment; though there is a late case in the Maine reports, where a verdict of heavy damages against a physician for alleged malpractice in a case of amputation was sustained on appeal, though the court expressly admitted that the verdict was found against the defendant on the ground of his error of judgment in not removing more than he did of the amputated limb. The physician's liability in cases of malpractice is ordinarily only a civil one, and the injury he does can usually be compensated by damages. But, in cases where death has followed the treatment, and it has seemed to be the direct consequence of the treatment, there have been, not unfrequently, charges of criminal malpractice preferred against the medical practitioner. To constitute a crime, there must be a malicious or criminal intent. This intent may exist in an actual design, or the law will infer it from gross rashness or want of circumspection.—Where no statutory prohibition intervenes, all regular and irregular practitioners are to be placed on the same footing. Leaving out of consideration cases of express malice, which would hardly be included under the designation of malpractice, our topic is reduced to those cases in which the charge is founded upon gross ignorance, gross negligence, or gross rashness. With particular reference to the charge of manslaughter, the law, especially in England, is that "if one, whether a medical man or not, profess to deal with the life or health of another, he is bound to use competent skill and sufficient attention; and if he cause the death of the other through a gross want of either of these, he will be guilty of manslaughter;" or as an eminent American authority, Mr. Bishop, states the law: "The carelessness in a medical man which, if death follow, will render him liable for manslaughter, is gross carelessness, or, as it is more strongly expressed, the grossest ignorance or most criminal inattention."—Criminal malpractice in relation to infanticide is considered under the title Pregnancy.

PHYSICK, Philip Syng, an American physician and surgeon, born in Philadelphia, July 7, 1768, died there, Dec. 15, 1837. He was graduated at the university of Pennsylvania in 1785, afterward studied medicine, and in 1788 went to London, where he became the private pupil of John Hunter. In 1790 he was admitted as house surgeon to St. George's hospital; and after residing for a year at Edinburgh, he returned in 1792 to Philadelphia, and there began the practice of medicine. In 1805 he was appointed professor of surgery in the university of Pennsylvania, in 1819 was transferred to the chair of anatomy, and in 1824 was elected president of the Philadelphia medical society. He wrote for medical journals accounts of cases he had treated, or of processes or instruments he had invented. He has been called the father of American surgery.

PHYSICS. See Natural Philosophy.

PHYSIOGNOMY (Gr. φύσις, nature, and γνῶναι, to know), the name given to the human countenance as indicative of the character, or to the art or science of discerning the character by the cast of the features. The claim of physiognomy to be considered a science rests upon the assumption that the habitual exercise of any feeling will leave upon the face a certain impression by enlarging, strengthening, and rendering permanent in position the muscles associated with such emotions. Thus to a certain extent every man is a believer in the science, because every man forms some opinion of those he sees, especially for the first time, by the expression of their countenances. The first elaborate attempt to elevate physiognomy to the rank of a science was made by Lavater in 1775–'8; but no special application can be made of the general rules he has furnished, on account of the number of exceptional cases arising from accidents of education, from the transmission of features from parents to children without the transmission of disposition, and from various other circumstances. Beside Lavater, others have written on the same subject, as Spurzheim in his "Phrenology in connection with Physiognomy" (Boston, 1834), and J. Cross, author of "An Attempt to establish Physiognomy upon Scientific Principles" (Glasgow, 1817).

PHYSIOLOGY (Gr. φυσις, nature, and λογος, doctrine), strictly speaking, the doctrine of nature, embracing a knowledge of all the physical and natural sciences, but now restricted to the science which treats of the vital actions peculiar to organized bodies, whether animal or vegetable; including histology, which treats of the elementary tissues as distinct from the organs which they compose, but excluding pathology, which concerns the vital functions in a state of disease. These distinctions, however, are arbitrary, as physiology cannot be dissociated from histology, nor be separated by a definite line from pathology, since it is impossible to determine exactly where health terminates and disease begins; some writers use the term biology, as comprehending the doctrine of life, whether in health or disease. Comparative physiology discusses the phenomena of life throughout the whole chain of beings, their differences and relations; physiology is general, special, or human, according as it takes up the subject in an abstract manner, as applied to a single species, or to man.—Living beings may be distinguished from inorganic matter by the peculiar arrangement of their heterogeneous parts, solid and fluid, mutually acting upon each other, by their definite form, and determinate bulk; by their origin from parents in the form of germs; by their powers of drawing sustenance from the external world, of excretion, and of growth; and by the phenomena of disease. In eggs and seeds the vital properties exist, though in a dormant state. Even presupposing the existence of organized structure, it is impossible to give a precise definition of life. The ancients held to the opinion that there is an independent entity or vital principle, whose union with the body causes life and its separation from it death. The moderns, however, regard life as a series of phenomena in organized beings, dependent partly on structure and chemical composition, whose various properties are brought into play by external stimuli. According to Bichat, "life is the sum total of the functions which resist death;" Treviranus makes it "the constant uniformity of phenomena with diversity of external influences;" and Beclard calls it "organization in action." Physiology, therefore, presupposes a knowledge of the structure of the tissues (whether molecules, cells, fibres, or tubes), and their properties and natural stimuli, including organic chemistry, and must be the basis of all just conclusions in pathology, therapeutics, and hygiene, whose avowed principles and practice are always the reflections of the physiological ideas of an age.—The theories of the principle of life may be divided into 3 groups: 1, those which consider the body an inert mass, into which an animating principle, called by various names, has been introduced; 2, in which life is explained by physical laws; 3, which recognize special vital properties or a vital force. In the 1st belongs the ancient theory of animism, according to which the world is vivified by a soul or spirit everywhere diffused, a portion of which gives life to man, animals, and plants. The ancient philosophers compared the human microcosm to the macrocosm of the universe, and recognized the same motor forces for organic and inorganic matter. Hippocrates considered unintelligent nature as the mysterious agent in the vital processes. Plato and Aristotle admitted 3 animating spirits, the vegetative in the plant, the vegetative and sensitive in the animal, and in man an additional intelligent and reasoning spirit, nobler and purer than the others. Paracelsus, in the 16th century, pretended to explain the functions of life by chemical and cabalistic arts, attributing to sidereal spirits and the planets a direct action upon the body, the sun upon the heart, the moon upon the brain, &c. Van Helmont afterward personified the vital principle under the name of *archæus*, a name previously employed by Paracelsus; this power was situated at the cardiac orifice of the stomach, and presided directly over digestion by the agency of the gastric juice; the *pylorus*, another dignitary of the organism, the doorkeeper of the stomach, opened or shut the passage into the intestine under its control; this duumvirate had its subordinates in each organ, which executed the special orders; health reigned during the peaceful and orderly state of the *archæus*, but its anger, fright, or irregularity produced diseases—an allegory under which we perceive the dimly shadowed idea of the sympathy and mutual dependence of organs now universally recognized; by the aid of a chemical ferment the *archæus* could organize matter directly, without the intervention of an egg. Stahl, early in the 18th century, though educated in the chemical school of physiology, found so many vital phenomena inexplicable by physical laws, that he sought for a new basis for the physiological edifice; insisting on the inertia of matter, organization to him was nothing without the rational soul, at the same time that the latter could do nothing without the body which was created for it; all physiological acts were established and directed by the soul in order to preserve the integrity of the body, by which it is brought into relation with the external world; most of the functions were destined to prevent the decomposition of the soft solids and liquids of the body, and all the movements were voluntary. Descartes, early in the 17th century, put an end to the theory of Van Helmont's *archæi*; notwithstanding the immense power he attributed to the soul, this philosopher's theories led to the establishment of the chemical and mechanical schools of physiology; he favored the former by introducing ferments, acidity, alkalinity, and effervescence of the humors, among the nutritive functions; and he influenced the latter by explaining the secretions by the round, cubic, or pyramidal forms of the molecules, and the functions of relation by a vibratory movement excited in the nerves by external impressions, propagated to the pineal gland in the brain, and terminating in the cerebral fibres on which it left material traces. Sylvius of Leyden, in the last half of the 17th century, explained all the functions of the body by the effervescence and fermentation of the fluids, excluding entirely the solids from his physiological scheme; food fermented in the stomach under the influence of the gastric fluids, and digestion was perfected by the actions established by the addition of the bile and the pancreatic secretion; the movement of the blood in the heart was due to the effervescence arising from the meeting of an oily volatile salt of the bile with a saccharine acid of the lymph, producing at the same time the animal heat; the vital spirits, entirely material, were prepared in the brain by distillation, having much of the properties and nature of alcohol; all diseases were caused by the predominance of this or that chemical element in the fluids, and to counteract a supposed acidity very powerful chemical preparations were rashly administered. While Sylvius taught these doctrines upon the continent, Willis promulgated similar ones in Great Britain; he made also the chyle effervesce in the heart under the influence of salt and sulphur, which took fire together and produced the vital flame. According to Haller, even the great mind of Newton was led astray by such vagaries as these. Many of the popular ideas of peccant humors, for which a multitude of empirical remedies are continually extolled and exhibited, date back to the chemical theories of the 17th century. Boerhaave and his school, early in the 18th century, substituted mechanical for chemical forces in physiology, explaining the phenomena of life on the principles of mechanics and mathematics according to the idea of Descartes; the then admitted doctrine of Harvey of the circulation of the blood and the discoveries of Galileo favored the progress of this school. Food was reduced in the stomach to minute particles by trituration; the circulation was a complete hydraulic machine, and the heart a perfect sucking and forcing pump; the weight of the blood and the loss of its motive power from friction in the vessels were exactly calculated, and the force of the heart's contraction estimated at 180,000 lbs.; the differences in the secretions were explained by the diameter, foldings, and number of the divisions of the vessels in the secreting organs, and by the diverse forms of the molecules, some of which were admitted and others excluded by these kinds of organic sieves; animal heat was the result of the friction of the blood globules against each other and against the walls of the minute vessels. Electricity was at one time considered the active agent of the vital functions, and certain analogies indeed favored this view; electricity dethroned the vital principle, and the barrier erected with so much labor between living and inorganic bodies was again thrown down. Glisson, in England, toward the middle of the 17th century, while the physical theories of life were in vogue, seems to have been the first to shed light on the path in which modern physiology has since so rapidly advanced; he maintained the activity of matter, and that all the functions of life depend on a property of living animal substance which he calls irritability, entirely independent of physical or mechanical forces—all parts of the body, even the bones and the fluids, possessing this property. This theory was completely forgotten until toward the middle of the 18th century, when various authors made use of the terms contractile force and tonicity. Haller (1747) admitted two properties, irritability and sensibility (*vis insita* and *vis nervea*); his irritability is the property of contracting under stimuli (the will for the ordinary muscles and their contents for the hollow ones), now styled contractility, distinct from and more powerful than elasticity, independent of the nervous force, and improperly called vital inasmuch as it is manifested after death; his sensibility is the power of perceiving the impressions derived from contact. This theory gave a great impulse to physiological science, which before this was in a very confused state. Barthez, in the last half of the 18th century, adopted the phrase vital principle, which he regarded as distinct from the soul, and as having its own proper existence and its motor and sensitive forces, the former residing in the muscles, the latter in the fluids and especially in the blood; this system met with great favor. Bichat, a quarter of a century later, reduced the vital properties to two, contractility and sensibility, each divided into the animal or voluntary and the organic. Brown, a few years before this, had elevated the property of incitability in the tissues into the vital principle; according to him, all diseases are either sthenic or asthenic, the vital force being increased in the former and diminished in the latter; this doctrine gave rise to the contra-stimulant practice of Rasori and others. Blumenbach, toward the end of the 18th century, attributed all the formative actions to a force which he called *nisus formativus*. Broussais, early in the 19th century, made pathology a branch of physiology, and gave to his system the name of physiological doctrine of disease; his celebrated theory placed essential fevers among the inflammations of the digestive tube, as forms of gastro-enteritis. Gerdy admits 17 vital principles, or so many distinct series of phenomena inexplicable by physical laws, a list which on his principles might be very greatly and inconveniently au-tended.—Modern physiology, as illustrated by Tiedemann and Gmelin, Burdach, Müller, Wagner, Bérard, Carpenter, and Todd and Bowman, recognizes that many of the changes which take place in the living body are effected by the same forces which act in the inorganic world and out of the body; but beside these chemical, mechanical, and electrical forces, there remains a principle peculiar to life, or the properties inherent in the various forms of organized structure—as much a part of them, and equally inexplicable, as are gravitation, magnetism, and electricity, properties inseparable from inorganic matter. The harmony and mutual adaptation of the phenomena within living organisms, as well as those manifested in the external universe, must alike be attributed to the infinite wisdom and power of the divine mind. The term "vital principle" should not be understood as intimating the existence of a separate and unknown cause of life, like the animism of the old writers, but be used simply as a convenient expression for "the sum total of the powers which are developed by the action of the vital properties of organized structures," stimulating instead of checking inquiry into their causes. Life, which it is the province of physiology to study and explain, involves the idea of constant change in the tissues composing an organism; the vital actions of the parts of a living body are mutually dependent on each other, and all are harmonious, during health, in the maintenance of the life of the organism as a whole. These actions are associated into groups called functions, which concur in effecting certain purposes, such as respiration and circulation. These functions may be divided into the organic or vegetative and the animal, according as they are concerned in the development and maintenance of the body, or render the individual a conscious and moving being; in the former belong those of digestion, absorption, assimilation, circulation, nutrition, respiration, secretion, and reproduction; in the latter those of sensation and motion. Though the organic, animal, and reproductive functions are intimately blended in the higher animals, as we descend the scale the animal or nervous functions gradually disappear (first mind, then voluntary motion, and finally sensation), until in the simplest animalcules we find nothing but an absorbing membrane capable of reproduction. To show at a glance the scope of physiological science, the following brief notice will be serviceable: A. The functions of the animal or intellectual life are concerned in establishing the relations of animals and man with surrounding objects; they constitute essentially man as a moral being, suppose an intellectual principle, and their organs are symmetrical and correspond by means of nerves with a central brain; this life is subjected to the law of sleep, is influenced by habit, begins with birth, and becomes gradually extinct with age; these functions are sensations (vision, hearing, touch, smell, and taste), the intellectual faculties, emotions, the will, voluntary motion, and sleep or the rest of the nervous and muscular systems. B. The functions of organic life have for their object the nutrition of the organs; most of their organs are of irregular shape, do not communicate with the brain, are independent of the will, and act without interruption from the moment of conception until death; they are digestion, absorption (lymphatic and venous), circulation, respiration, exhalation, secretion, and reproduction (with the secretions of sperm and milk, and the phenomena of menstruation, conception, and gestation).—The functions concerned in these vital processes will be found treated under Absorption, Abstinence, Adipose, Age, Aliment, Animal, Animal Electricity, Animal Heat, Anthropology, Bile, Blood, Bone, Brain, Capillary Vessels, Cartilage, Cell, Chyle, Chyme, Circulation, Comparative Anatomy, Dentition, Dietetics, Digestion, Embryology, Gland, Heart, Histology, Hunger, Kidney, Liver, Lungs, Lymph, Muscle, Nervous System, Nutrition, Perspiration, Respiration, Secretion, Skin, Voice, &c. Beside the authors above named, reference may be made to the writings of Adelon, Sir Charles Bell, Bernard, Brown-Séquard, Flourens, Liebig, Longet, Magendie, Marshall Hall, Matteucci, Paget, Richerand, Roget, Rudolphi, Serres, Simon, Valentin, Verdeil, and Robin, in Europe; and in America to those of Dalton, Draper, Dunglison, and Paine, with the numerous references therein named.

PIACENZA (anc. *Placentia*), a city of Italy, capital of the former duchy of Parma and of a province of the same name, situated in an extensive and fertile plain on the right bank of the Po, about 2 m. E. from its junction with the Trebia, and nearly equidistant from Parma and Milan; pop. 31,403. It is fortified by a citadel and old earthern ramparts and ditches. It has a cathedral, built in the 12th century, and other churches; a *podesteria* or town house; a library of 30,000 volumes, &c. Cotton, silk, firearms, &c., are manufactured.—Placentia became in 219 B. C. the seat of a Roman colony, and the next year the battle of the Trebia between Hannibal and Sempronius was fought in its neighborhood. It remained faithful to Rome at a later period of the war, and withstood a protracted siege by Hasdrubal, but in 200 B. C. it was captured by the Gauls. The Æmilian way, constructed not many years after, originally terminated at Placentia. In the war between Marius and Sylla, Lucullus, the general of the latter, defeated the partisans of Carbo in 82 B. C. in its vicinity; and here also the mutiny in Cæsar's camp broke out during the war between him and Pompey. During the empire Placentia seems to have been one of the most flourishing towns of Gallia Cispadana, and the desolation which overtook the whole of that province in the barbarian irruption did not entirely destroy its importance. In 1126 it became an independent republic, and in 1254 subject to lords of the families of Pallavicino, Scotti, and Landi, and subsequently to the Visconti of Milan. In 1447 it revolted, but was retaken the same year by the Milanese under the command of Francesco Sforza. In 1512, after the battle of Ravenna, it came into the hands of the popes, and in 1545 Paul III. presented it to his son Pietro Luigi Farnese, along with the duchy of Parma, of which from that time it formed a part. In June, 1799, the French were defeated near it by Suwaroff. In 1860 it was annexed to the kingdom of Sardinia.

PIACENZA, Duke of. See Lebrun, Charles François.

PIANOFORTE (Ital. *piano*, soft, and *forte*, loud), a musical instrument, the tones of which are elicited by means of the blows of small hammers upon a series of tightly stretched elastic strings; the hammers being caused, through certain connections, to rise upon striking the corresponding keys of a finger board, and the tones being strengthened and rendered melodious by the reciprocal vibrations of a properly prepared sounding board, over and near to which the strings are stretched. In his recent history of the pianoforte, Dr. Rimbault traces the first principle of the instrument, the stretched string, to the ancient lyre; and from this he shows a course of gradual modification through the forms of the harp, the psaltery, the dulcimer, &c. The first marked approach to the pianoforte appears in the transition from the dulcimer to the clavicitherium (keyed cithara), which was a small oblong box, holding a series of strings in triangle form, and struck by *plectra* of quill attached to the inner ends of the keys. This application of the keyboard to stringed instruments is believed to have been first made in the 12th century. Next followed the clavichord, which continued in favor for about 6 centuries, though in part giving place to varieties known as the cymbal and manichord. It is remarkable that the damper, a contrivance allowed to fall or rest upon the string, so as to arrest its vibration when the key has been released by the finger, was introduced at an early period into the clavichord. An improvement upon the keyed cithara, called the virginal, was very popular with Queen Elizabeth and ladies of her time. In this the strings, of catgut, were at once struck and pulled by pieces of quill fixed in the upper end of short, upright jacks upon the inner ends of the keys. The spinet, of about the same period (1500–1700), was a larger box of triangular form, having sometimes 49 strings, some of steel wire, and also played on by means of a jack and quill (spina). The body of the so called square pianoforte, which is oblong in form, is evidently copied from that of the clavichord; while the almost triangular arrangement of the strings as clearly has its origin in the form assumed by the strings of the spinet. The harpsichord was substantially a horizontal harp, played by means of keys with jacks and quills. It was manufactured in Italy early in the 16th century, and long maintained its place, being extended from 4 to at least 6 octaves, and often having double strings; while into some of its improved forms were introduced pedals, and even arrangements for transposing the music by shifting the action of the keys to different sets of strings. The most distinguished harpsichord maker of London, from about the year 1740 to 1775, was Burckhardt Tschudi, whose son-in-law, John Broadwood, was one of the earliest piano makers in England, founding the firm still represented in London under this name. The transition from the instruments now named to the piano appears to have taken place about 150 years since; and yet, unless we may rely on the article by Maffei in the *Giornale de' letterati d'Italia* (Venice, 1711), we must regard the place of this important invention and the inventor's name as obscure, or even lost. The invention has been claimed in turn by Italians, Germans, French, and English. By some writers it is asserted that the first improvement from the spinet and harpsichord consisted merely in the introduction into the latter of hammers, formed each of a leather button on the top of a short stout wire, taking the place of the jack. These hammers could not readily enough quit the string after striking, and its tone was in this way deadened. Such a change would form no marked improvement on those instruments. But the article of Maffei, above mentioned, which is full and specific, and accompanied with a cut, and which is translated at length in Rimbault's work, describes, as having been constructed by Bartolommeo Christofali, a harpsichord maker of Padua, an instrument in which the strings were vibrated by hammers, and each through a complex mechanism, the parts of which were a key, lever, movable tongue acting on the hammer, the hammer, its rest of silk strings, and a damper. Such a mechanism would allow of the rapid stroke and sudden recedence of the hammer, leaving the string free to vibrate until, by releasing the key, the damper should be allowed to check its movement; and thus it would accomplish in a manner all that was aimed at in the earlier "actions" of German and English makers. If this account be genuine, it settles a long controversy, and proves Christofali (before 1711) the real inventor of the pianoforte. In 1716 Marius, a French maker of harpsichords, submitted to the academy four forms of instruments of which he claimed to be the inventor, and termed by him *clavecins à maillets* (hammer harpsichords). In some of these the hammers were in a degree detached from the keys. A third claimant to the invention is Christopher Gottlieb Schröter, who asserted some years later the fact of his having devised in 1717 an arrangement of keys, springs, and hammers, which others were already employing without due credit. He is believed by some to have suggested the present name by his statement, in a published account in 1763, that on his instruments the performer "at pleasure might play *forte* or *piano*." At the outset, however, the instrument was not appreciated, a fact that may account for the obscurity resting over its origin. Silbermann of Freyburg first became somewhat popular as a manufacturer; and it is known that in 1747 Frederic the Great was so pleased with some pianofortes of his, that he purchased the whole stock, 15 in all; but these were still so imperfect that they were allowed to fall into disuse when, in 1765, the king received an improved harpsichord from Tschudi of London. Of these German instruments, which it would appear were of the square form, the strings were double, and the compass not more than 4½ or 5 octaves. They were adopted, however, by Haydn, Gluck, and other composers of the time; one made for Gluck in 1772 was 4½ feet long by 2 broad, the sounding board at one end only, and the strings mere threads compared with those now in use. The first piano known in England (about 1757) was made by an English monk at Rome. About 1760 many German mechanics arrived in England, two of whom, Viator and Backers, became known by their improvements in pianos. In 1767 the piano was introduced on the stage of Covent Garden theatre as "a new instrument," according to a playbill bearing date May 16 of that year, now in possession of the Messrs. Broadwood. About 1755 the poet Mason had invented an action for the piano; and although this seems not to have come into permanent use, he has by some been claimed even as the originator of the instrument. In 1774 a patent was granted to Joseph Merlin for a compound harpsichord, having hammers on the plan of the pianoforte. A more positive claim on the part of English makers is that concerning the first invention of a grand action, it being admitted that about 1772 Americus Backers, a German, assisted by John Broadwood and Robert Stodart, all in the employ of Tschudi, together succeeded in applying an action, similar to that then in use in pianofortes, to the harpsichord. The action devised by them is essentially the same as that still used by the firms of Broadwood and Stodart in London, early adopted by Pleyel and by Herz in Paris, and known among European mechanics as the English action, in this country more commonly as the Pleyel action. It is marked by simplicity, efficiency, and durability, whence it is called also the direct action; and its improved form is substantially that now used by Messrs. Chickering and sons of Boston, in their square pianos. From the time of this change the harpsichord makers rapidly became piano makers. The earliest entry of a piano on the books of Broadwood and co. occurs under the date of 1771; of a grand piano, 1781. Further facts in the history of the instrument will be better understood after some account of its construction.—The piano is now made in three distinctive forms: the grand, the square, and the upright; in the first two the strings run horizontally, in the third vertically or obliquely upward. Of these, the upright is the form most common in England, the square in the United States. Indeed, the square pianos of the United States probably surpass in workmanship and perfection of tone those of any other country; but the grand piano is that adapted to the introduction of the best mechanism, and hence it is always chosen in cases where, as in a concert instrument, the greatest power and brilliancy are required. In the grand, all the octaves, save about two lowest in the scale, have for each note 3 strings attuned in unison and struck at once by the same hammer; from 4 to 7 of the lowest strings may be single, and through about another octave and a half two strings to each note are often used. The largest of these instruments are known as full or concert grands; a medium size, as semi-grands; a size still less, as parlor grands. The square piano was, until the application to it of mechanism somewhat similar to that of the grands, a very inferior instrument. The upright was at first a grand set on end, and raised on legs; the hammers over or in front of the strings, striking them at their lower ends. In other forms, the hammers are almost invariably below the strings. The first patent for an upright appears to have been granted to William Stodart in 1795. In 1807 William Southwell of Dublin reduced the dimensions of the upright, before very unwieldy, replacing it by the "cabinet," in which also the frame was lowered, and by means of long slender stickers the strings were struck above. In 1811 Robert Wornum introduced the "cottage" upright, 4 to 5 feet high; and in 1827 the "piccolo," rising not more than 3½ feet from the floor. The compass of the scale of piano keys did not at first exceed 5 octaves, from FF, or the F below the lowest of the violoncello, to F in alt. It was next extended to C above; then to F yet above this, making 6 octaves; by a third extension, to the C below; and then, by an added treble string, to G. Thus its compass came to be from CCC (corresponding to about 64 single vibrations per second, and to an open organ pipe of 16 feet length) to G, 6½ octaves above. Pianos of large size are now commonly made with a compass of 7 octaves, the base reaching to about A below CCC, and the treble being extended also by one or more strings. In the London exhibition of 1851 was a piano of 7½, and another of 8 octaves. The corresponding enlargement of the instrument, and especially of the sound board, gives an augmented volume and force of tone; but the deficient quality of the uppermost notes has led good judges to question whether any real advantage is gained by exceeding 7 octaves.—The making of pianos is conveniently divisible into 4 parts: 1, the framing and sound board; 2, the stringing; 3, the keys and action; 4, the ornamental or other case. (1.) In pianos of full to largest size, the sum of the tensions of the strings, when properly stretched in attuning, is not less than from 6 to 12 tons. It follows that the framing, or those parts within the case which serve as a strut or stretcher between the ends of the strings, and which are to resist this enormous pull, must be made correspondingly strong and rigid; since by any gradual yielding under the pull of the strings, their lengths and tensions, and hence their tone, must undergo proportionate change. In the earlier instruments, having small strings, the frame was of timber only. Builders then sought only truthfulness of tone, depth and power being out of the question. With the progress of metallurgy, and the gradual introduction of iron structures, this metal came to be used for the piano frame (*i. e.*, for the platform or parts receiving the strings, which is not to be confounded with the case). This frame was cast in a few parts, which were united by bolts or screws; and this plan is still followed in London, and indeed in Europe generally. In pianos of all forms, the scale of lengths of successive strings required to yield the notes through the compass of the instrument results in a series of strings conveniently grouped in a form identical with or approximating that familiarly known in the harp. In grands, the inner or remote ends of the strings run in a curve representing the curved side of the harp, the treble strings lying to the right hand. In squares, usually, the harp curve is represented by the ends of the strings toward the right hand side of the performer, and lying nearer to him. The ends of the strings corresponding to the straight side of the harp thus lie, in grands, in front, terminating in this case, however, in a less marked curve; and the like extremities in the squares, which until recently always terminated in a straight line, lie to the left hand and back of the instrument. It is near to this part of the strings—at the remote side in squares, and in front in grands—that the hammers are always made to strike, the proper distance of the point of striking being about ⅐ to ⅑ the entire length of each string. The parts of the framing and connections of the strings can now be understood. Always at the ends, which are arranged in what we have called the harp curve, the strings are permanently fastened to pins or studs, now made to enter and project directly from the iron plate. About each one of these, called the hitch pins, a string is in some cases bent, so as to return to the other side, corresponding to two single wires; in other cases, each single wire is secured to a pin by terminating in a loop. In either case, the strings terminate in ends at the opposite (answering to the straight) side, and each is here wound about a larger movable pin, by turning which it is that the tuner increases or relaxes the tension. The plate in which stand the hitch pins is termed the string plate; that receiving and giving support to the tuning pins (wrest pins), the wrest plank; and this, owing to the greater wearonsness of wood than of iron, is almost invariably a wooden strip or plank, though in various ways let into and supported by the iron castings which furnish the required strength to the part. The string plate and wrest plank are secured by bolts and otherwise to firm timbers beneath them; the whole being received within the parts of the case. But the chief part of the strain of the strings is borne, in grands, by means of several strong iron or steel bars rising above the strings, and running parallel with them, and in squares by one or two such bars, these being formerly, and in Europe still in most instances, cast separately, and then firmly screwed down to the iron plates at both ends. Two important improvements in connection with the framing and arrangement of the strings are due to Mr. Jonas Chickering of Boston. He was the first to introduce the plan of casting the entire iron framing with the parallel bars in one piece. This plan, adopted by him in 1838, and cited by Rimbault as "the American plan," is believed to have added greatly to the solidity of the instrument and the permanence and purity of the tone, and to have facilitated the addition of strings, thus enlarging the resources of the keyboard. Mr. Chickering also invented, and first used in Nov. 1845, the circular scale for square pianos, now generally employed by manufacturers in America and Europe. This consists in giving to the row of tuning pins and the wrest planks, previously straight in these instruments, a curved disposition, answering nearly to an arc of a circle; the advantage being that the strings become less crowded, larger hammers and a more direct blow can be secured, and the tone is both strengthened and improved. This improvement was not patented, the inventor preferring to regard it as one of the things of which all makers should have the use. In grand pianos, the framing and sound board are severed across in front, to allow of the rise of the hammers, this part being strengthened by arches of metal and otherwise. The system of metallic bracing, first generally introduced by the invention of Thom and Allen in 1820, was brought nearly to its present form, including the tension bars above referred to, by Pierre Erard of Paris in 1825. The sounding board is a sheet of thin, carefully prepared board, usually made of the best Swiss pine, and free from knots and flaws, strengthened on the under side with small transverse ribs, and now made to extend across nearly the entire instrument, beneath the strings. Its edges merely are grasped between parts of the frame and case, and sometimes at particular points only, so that the middle portion is left free to vibrate. On its perfection the quality of the tones must depend in a high degree. (2.) At the first, steel wires were used for the treble notes of the pianoforte, and brass for the base; and as all the wires were short, those for the lower notes were wound or overlapped by wire of less thickness, for the purpose of increasing their weight, and this to a greater extent than is now required. Mr. Collard introduced in 1827 the plan of bending each wire about the hitch pin, as now commonly practised, thus obviating the tendency of the string to yield, twist, or break, in consequence of the noose formed at the end. Steel wire was also introduced throughout. A few of the lower strings are still wound, the upper of these with soft iron, the lower with copper; and this lapping is now with finer wire, and very close. The length of the vibrating part of each string is determined by the places of two bridges, over or through holes in which the strings are stretched. The bridge nearest the hitch pins is upon and attached to the sound board, to which it aids in communicating the vibration of the strings; the other runs along the edge of the wrest plank or plate, near to the tuning pins. Beyond the bridges at either end, the string is known as dead wire, and any interfering vibration of this part is prevented by interlacing these ends with stout tape, or in other ways. When both supports determining the vibrating length of the string were bridges merely, the blow of the hammer from below tended slightly to elongate the string and to lift it from the nearer bridge, and so altered the tone. To prevent this result, Sébastien Érard invented in 1808 the plan of passing the strings at the end struck by the hammers through holes piercing the bridge or rim projecting from the wrest plank, and so shaping the latter that from these holes the strings slope directly upward to the pins. The effect of this important improvement, termed the upward bearing, is that the string is no longer lifted or appreciably lengthened by the blow of the hammer, since to this the strain of the string is now directly opposed; and its length remaining constant, its pitch is equable and its tone stronger. An improvement called the *à graffe* was also introduced at some unknown date, in which the bridge just spoken of is conveniently replaced by a stud or pin for each string, pierced with 2 or 3 holes for the wires, and made fast below in the wrest plank. This we have seen in a Swiss piano many years old. (3.) By the action of the piano is to be understood the mechanism, consisting of several small interposed parts, by which the pressure of the finger upon each key is to be transmitted in the most effective manner through the hammer to the corresponding string. The oldest of the actions which have been (in modified forms) retained, are those of the square piano. In the original of these the key had upon it near its inner end a lifter of stout wire capped with a soft leather button, this striking and elevating the hammer; while still beyond this rose a sticker which at the same time lifted from the wire a damper above it—a lever having a bit of soft cloth at the end; on releasing the key, this damper returned upon the string, checking its vibration. This arrangement formed the single action. Its faults were that the tone was thin and wiry; that in playing very *piano* the pressure on the key did not always cause the hammer to reach the string; while, if the hammer rest was brought too near the string, the hammer did not quit the latter soon enough, and the effect of this was termed blocking. To remedy these defects, Longman and co. introduced the hopper or grasshopper, invented in 1786 by John Gieb. This hopper took the place of the lifter; it was a jointed upright piece which, when the key was pressed down, engaged in a notch under the hammer, and just before the instant of striking slipped past the end of the hammer, allowing this after the blow suddenly to fall. With this was employed also a second or under hammer, multiplying the velocity of the first, on the principle of the compound lever. This mechanism was the double action, still substantially in use with many makers in uprights and squares. To this was afterward added the Irish damper, the invention of Southwell (1794-'8), which was simply an upright rod, with a piece of soft cloth above, which the key, so long as it remained depressed, lifted off the string. Still, the hammers would sometimes rebound from the string with such force as to return upon it, checking its sound. To remedy this, a small, inclined, rough surface of felt was so fixed on a wire support as to be rubbed by the head of the hammer in its descent, and thus gradually to destroy its velocity; this was called the check. The English grand action, so called, already alluded to as that of Backers, adopted by Broadwood, Stodart, and others, consisted of a key, a jack (lever, in place of the hopper), a button so placed as to regulate the sweep of the jack, a spring pressing to restore the jack to its place after the movement, a hammer on the but of which the jack acted, the check, and a damper arrangement, of which various forms could be employed, with rails and sockets connecting or fixing the needful points. But in this arrangement it was still a defect that, after a stroke of the hammer, the jack could not reëngage it until, by release of the key, the parts had returned to their first position. This required time, and any note could not be rapidly repeated. The defect was first remedied by an invention of Sébastien Érard in 1821, improved in 1827, termed the repetition action. This was an improvement upon a previous action of his, which as now modified, under the name of the French action, is still in use with many makers in America and Europe, and the origin of which is believed to be due to Petzold. In the repetition action, consisting of an arrangement of levers and springs too complex to be described here, the hammer is caused to be, through its whole sweep, at the command of the player, so that the note can be reproduced at half stroke, or at any fraction of an entire stroke. To secure this result, when the hammer recoils from the string, it is, by means of a roller, lever, and spring, upheld so long as the key is not entirely released, and in such a way that it can neither return to the string nor fall; and while thus suspended near the string, its blow upon the string may be, by aid of an escapement button, repeated at the pleasure of the player. The French repetition action is thus complex and delicate. Broadwood retained the English grand action, applying to it directly a repetition adapted from the French by Southwell, probably in 1827. This was accomplished by passing through the hammer butt a block or bar, a spring pressing upon this so that when the jack passes the notch it is caught by this bar, and the hammer is sustained ready to repeat the blow, until, as before, the key is entirely released. The escapement button also appears in this arrangement, and a second spring determining the height at which the hammer shall rest. The varieties of grand action are very great, those used in the United States being all based on either the English, now described, or the French of Petzold and Érard. The Messrs. Chickering have employed several grand actions, the chief of which are three. In the first, mainly their own invention, an under hammer is sustained for the repetition movement by a spring lifting it from a spur near the foot of the jack, until the latter falls by release of the key; in the second, the Howe action, repetition is secured by acting directly on the hammer, without under hammer or lever; the third is a modification of Érard's. Their establishment for the manufacture of pianos is the second in importance of those now existing; the order being as follows: Broadwoods, Chickerings, Collards, Pleyel, and Érards. Stops were early introduced into the piano, but, save in parts of continental Europe, they have been abandoned; several pedals are there also used, but in England and this country only two, one for *forte* effects, the other for *piano*. The *forte* pedal is quite effectual, and beside not injurious to the instrument. The earlier *piano* pedal, passing the action to one string, is straining to the centres of the hammers, and apt to disturb the tuning of the unisons—the strings intended to yield the same note. The *jeu céleste*, a later pedal arrangement, obviates these defects. In this, tongues or strips of soft leather or wool are so held, that by pressure on the pedal they can be raised between the strings and the hammers, thus softening the sound. This, of late somewhat contested, we have seen in a piano of Petzold's, marked 1823; and in the same also the long or full sound board, supposed by many to have been more recently introduced, is found. It should be added that the hammers are of wood, the heads covered, according to size, with one or more layers of thick and firm felt. This material, soft woollen, &c., are introduced in many parts also to prevent the click or rattling which would otherwise attend the movements. Various contrivances have been resorted to for the purpose of securing sustained sounds in the pianoforte; a very good example of these was Mott's *sostinente* pianoforte (1817), in which the continued tone was obtained by communicating the vibration of the strings to silk threads and skeins arranged in a peculiar manner. The æolian attachment of M. Isoard consists in causing a current of air, supplied by a bellows, to act on the string, thus prolonging its tone on the principle of the æolian harp. A similar effect is produced by the æolian attachment invented by Mr. Obed Coleman of Barnstable, Mass., about 1842. In "transposing pianofortes," the keyboard and action, or the strings and framing, can be shifted laterally, so as to cause the hammers to strike a different set of strings, thus transposing the music, according to the arrangement, a half or whole note, or several notes, upward or downward. Melographic pianos, or those which, by added mechanism, shall register and preserve the improvisations of a composer, have been attempted by many, dating from the time of Hohlfeld, who, at the suggestion of Euler, essayed this in 1752. Probably the most successful attempt of this kind is that of M. Debain of Paris, exhibited in 1851. (4.) It is unnecessary here to detail particulars concerning the case of the piano, or concerning the various woods, metals, and other materials found to be best fitted to enter into its construction. The manufacture of the instrument gives employment to a great variety of artisans, among whom the work of the several parts is minutely divided; these are the key makers, hammer makers, hammer leatherers, string makers, stringers, case makers, finishers, &c. The construction is a slow process, and cannot well be hurried; a grand piano usually requiring to be 6 months in making.—A few words require to be added in respect to certain other modifications introduced into the construction of the piano in the United States. Mr. F. C. Lighte of New York has patented a peculiar construction of the iron frame holding the wrest plank, by means of which he considers the strain of the strings to be more firmly and equably sustained than in other grand pianos. Another patent of Mr. Lighte covers the application about the screws by which the frame is bolted down, &c., of collars or washers of rubber, or other yielding material; by this means he believes that the tendency of the iron frame to control the vibratory parts of the instrument is obviated, and the metallic character of the tones sometimes imparted by the iron frame overcome. Many makers employ what is called the overstrung base. This is an arrangement by which at least two of the lowest octaves are raised, running diagonally in respect to the other strings, above them, and barely clearing them where at the striking end the hammers rise. Who first introduced the overstrung base may not now be known; but it is found in a Russian piano now in New York, made at least 15 years since. In squares, one advantage offered by this plan is that of greater length for the base strings than could otherwise be obtained; but in grands, space enough is obtained without this change, and it is doubtful whether in these it affords any advantage. In any case, the two sets of strings are differently circumstanced; and in consequence an apparent break or inequality of tone is apt to occur in passing from one to the other, which it is difficult for the maker or the player wholly to obviate. Mr. Spencer B. Driggs placed in the New York exhibition of 1853 a piano which he claimed to possess some points of peculiar excellence. He constructed the sound board double, an upper and a lower, each firmly secured at the edges, and the strengthening ribs being dispensed with in the upper. Thus he obtained a sounding chamber and walls having some of the characteristics of those of the violin; and a marked volume and sweetness of the tones of the instrument are said to have been the result. Mr. Driggs claims more recently to have invented a new scale for the arrangement of the strings of the pianoforte. In this he discards the harp shape, so placing the bridges that, from the treble to the base, each string, for whole or half note, is exactly doubled in length for its octave below. He believes that thus the scale is made not only mathematically correct, but acoustically true; a view, however, which appears to conflict with relations established in the nature of music between the intervals and their octaves. In the London exhibition (1851), Mr. Pirsson of New York displayed a double grand pianoforte—two grands in a large oblong case, the players sitting facing each other. The earliest makers in the United States are believed to have been Mr. Osborn and Mr. J. Thurston; and after these Mr. Stodart, from the London house of that name. Statistics of the manufacture of pianos in the United States are at the present time hardly accessible. The Messrs. Chickering, established in 1823, have now reached (March, 1861) the number of 23,800 pianofortes manufactured by them. The Messrs. Collard of London sold during 20 years, to 1851, about 32,000 pianofortes; the Messrs. Broadwood, during the same time, 45,863. In 1853 the production in all England was estimated at 1,500 instruments per week; of these not quite 10 per cent. were grands, a like proportion squares, and the remainder uprights.—Some degree of error prevails in regard to the mode of securing force of tones, in performing on the pianoforte. Loudness of tone is not due to the force or momentum with which the key is struck, but to the time that is occupied in depressing the key, *i. e.*, to the velocity given to the hammer. If in one case the time consumed in putting down the key can be made but half what it was in another, the velocity of the hammer will be doubled, and the intensity of the blow and of the tone will be correspondingly augmented. Hence, in performing, it is easy to waste much strength to no purpose; and much of the gesturing, and even of the action of the hand and arm in playing, is simply of this character. Still it is true, as Thalberg has said, that the touch of the keys of no two players is alike; and that differences of style and degrees of excellence in playing depend very largely on this cause. Between the mind of the player and the strings there is a double mechanical action: first, that of the player's hand and fingers; secondly, that by which the keys act upon the strings. Evidently, the action of the piano, which continues that of the fingers, should have a delicacy and power as nearly as possible answering to that of the hand of the player; and not only will the touch of each performer be characteristic, but beside, for the same performer, every variation in the action will occasion a corresponding difference in the tones and susceptibility of expression of the instrument. Finally, by contributing to refined enjoyments, and at home, the piano takes rank in social importance before any other musical instrument.—For further information respecting the history and construction of the pianoforte, the reader is referred to Fischhof's *Versuch einer Geschichte des Clavier-Baues* (8vo., Vienna, 1853); Pole's "Musical Instruments in the Exhibition of 1851" (printed for private circulation); and to Rimbault's "Pianoforte," &c. (4to., London, 1860). In respect to performing, tuning, &c., see works published in England by Czerny, Kalkbrenner, and Chaulieu, and various other popular manuals on the subject.

PIARISTS (Lat. *pius*, pious), or Fathers (Regular Clerks) of the Pious Schools, a religious order in the Roman Catholic church, whose members take, in addition to the three common monastic vows, a fourth, to devote themselves to the gratuitous instruction of youth. The order was founded at Rome by St. Joseph Calasanza (born in 1556, died in 1648), a Spanish priest of noble birth, who, in 1597, in union with three other priests, opened a free school, which was soon attended by upward of 700 children. In 1617 Pope Paul V. conferred on the corporation of teachers the rank of a religious congregation, and in 1621 Gregory XV. gave them all the privileges of a religious order. The same pope in 1622 confirmed their rule, and appointed Calasanza their first general. The order was suppressed by Innocent X. and reëstablished by Clement IX. It spread rapidly through Italy, Germany, and Poland, and became eminently popular. It even, to a large extent, escaped the opposition to which in the 18th and 19th centuries many other orders had to succumb. Thus the Piarists suffered less than any other order from the reformatory decrees of the emperor Joseph II. of Austria, and were exempted from the general suppression of convents in Spain in 1836. More recently they were equally favored in Sardinia (1855) and in other parts of Italy (1860). In 1860 they possessed 28 houses in Italy, 33 in Germany, 32 in Hungary and the dependent countries, 14 in Poland, and about 30 in Spain. They have been recently reintroduced into Cuba. Their constitution is similar to that of the Jesuits. At the head of the order is a general, who is elected by the general chapter for 6 years, and resides together with a procurator-general and two assistants at Rome. Every province is governed by a provincial, and every college has a rector and vice-rector.

PIAST, a Polish husbandman of Kruszwice on Lake Goplo, who, according to national legends, was elected ruler of Poland, at a time of anarchy and dissension, about the middle of the 9th century. Historians regard his son Ziemowit as the founder of the dynasty of the Piasts, who reigned in Poland for more than 500 years in the male line (860–1370), the last being Casimir the Great, in the duchy of Masovia down to 1526, and in a part of Silesia down to 1675, becoming extinct with George William, duke of Liegnitz. (See POLAND.)

PIASTER (Span. and Ital. *piastra*), a silver coin and money of account, used chiefly in Turkey and the Levant, and called in Turkish *ghersh*. It is of very variable value. The piaster of Mocha, an imaginary money of account, is worth 1*s.* 8½*d.* sterling; that of Constantinople, a coin about the size of a half dime, was rated, under the new system of coinage promulgated in 1845, at 4.3 cents; in 1861 it was worth 2.7 cents. The term piaster is also applied to the Spanish and Italian dollars, and is used in South America and the East Indies.

PIAUHI, or PIAUHY, an E. province of Brazil, bounded N. by the Atlantic, E. by the provinces of Ceará and Pernambuco, S. by Bahia and Goyaz, and W. by Maranhão, extending from lat. 2° 42′ to 11° 20′ S., and from long. 40° 20′ to 47° W.; extreme length 740 m., breadth 310 m.; area, 92,000 sq. m.; pop. in 1856, 150,400. Oeiras, the capital, and the only seaport, is at the E. mouth of the Parnahiba. The Parnahiba separates Piauhi from Maranhão. The surface is generally flat, broken at intervals by small hills, and rising into mountains on the S. and S. E. frontiers. Iron, alum stone, copperas, saltpetre, and salt are found. Sugar cane, rice, cotton, tobacco, and mandioc are cultivated, and various species of palm are abundant. Large numbers of horses and horned cattle are reared. Piauhi sends a senator and 3 deputies to the general legislature.

PIAZZI, GIUSEPPE, an Italian astronomer, born in Ponte in the Valtelline, July 16, 1746, died in Naples, July 22, 1826. He entered the order of the Theatins, and after studying at Milan, Turin, and Rome, under Tiraboschi, Beccaria, Lesueur, and Jacquier, became in 1770 professor of mathematics in the newly founded university of Malta. After the breaking up of that institution, he returned to Italy, and became professor of philosophy and mathematics in the college of nobles at Ravenna. But the religious views advanced in his philosophical theses, deemed "too bold for so young a divine," brought him into trouble here, as they had before done at Genoa; and he went to Cremona, where he became a priest, and afterward was professor of dogmatic theology at San Andrea della Valle in Rome, where he had as a colleague Father Chiaramonti, who subsequently became pope under the title of Pius VII. In 1780 he was appointed professor of astronomy and higher mathematics in Palermo, where through his labors and under his direction an observatory was built and finished in 1791. To obtain the instruments for it, he travelled to France and England, making the acquaintance of Lalande, Delambre, Bailly, Legendre, Maskelyne, Herschel, and others. On Jan. 1, 1801, he discovered Ceres, the first of the asteroids known to exist between the orbits of Jupiter and Mars. In 1803, under the title of *Stellarum Inerrantium Positiones*, he published a catalogue of 6,748 stars, the results of the observations of 10 years. In 1814 he published a second catalogue embracing 7,646 stars, of which the 7th annual report of the London astronomical society says: "It exceeds every thing of the kind which preceded it, and shows more powerfully than words can express what may be effected by the talents and assiduity of one individual." In 1817 he was called to Naples to take charge of the new observatory erected on the heights of Capo di Monte. He wrote many valuable works on astronomy.

PICARD, JEAN, a French astronomer, born at La Flèche in 1620, died in 1682 or 1684. He assisted Gassendi in observing the solar eclipse of Aug. 15, 1645, was appointed in 1665 his successor in the chair of astronomy at the college of France, and became in 1666 one of the original members of the academy of sciences. His introduction of several improvements in practical geometry greatly increased the exactness of scientific observations. In connection with Auzout he reinvented the micrometer, was the first to apply a telescope in the measurement of angles, devised methods of verification in astronomical investigations, made the first exact measurement of a degree of the meridian, and pointed out the two fold phenomena of nutation and aberration, afterward explained by Bradley. He also introduced the modern method of determining the right ascension of the stars by employing a pendulum to note the instant of their meridional passages. In order to make the observations of Tycho Brahe more accessible to astronomers, he visited Uranienburg in 1671 to ascertain the latitude and longitude of the observatory at that place. He welcomed to France the celebrated Cassini; and when, through his exertions, the observatory of Paris was established, he saw without envy the Italian philosopher promoted to the directorship of an institution of which he himself was the father. He wrote valuable astronomical works.

PICARDY, an ancient province of N. France, bounded N. by the straits of Dover and Artois, E. by Champagne, S. by Ile de France, and W. by the English channel and Normandy. It was divided into Upper Picardy, including the districts of Amiénois, Santerre, Vermandois, Thiérache, Laonnais, Soissonnais, Noyonnais, Valois, and Beauvaisis; and Lower Picardy, comprising the *pays reconquis*, Boulonnais, Ponthieu, and Vimeux. The name of Picardy is not traced further back than the 13th century; it was then applied to several counties held by vassals of the count of Flanders, and was derived either from the Latin *picardus*, pikeman, as the inhabitants were celebrated for their skilful handling of the pike, or from the old French *picard*, boisterous, quarrelsome. The province was subdued by the English under the reigns in France of Philip VI. and Charles VI., reconquered by Charles VII., who mortgaged it to the duke of Burgundy, and finally restored to the crown in 1463, under Louis XI. Its capital was Amiens. It forms now the department of Somme and parts of Pas-de-Calais, Aisne, and Oise.

PICCINI, Nicola, an Italian composer, born in Bari, in the kingdom of Naples, in 1728, died in Passy, near Paris, May 7, 1800. At 14 years of age he was placed in the conservatory of San Onofrio at Naples, where he studied under Leo and Durante for upward of 12 years. He first wrote several comic operas for the theatres of Naples, after which he produced at Rome in 1758 his *Alessandro nell' Indie*, a serious opera, containing one of the finest overtures ever composed. Two years later appeared his *Cecchina*, or *La buona figliuola*, the drama of which, by Goldoni, was founded upon Richardson's "Pamela." It obtained a popularity without a precedent. It was succeeded by *Olimpiade*, a subject previously set by Pergolesi and other celebrated composers. For nearly 15 years Piccini continued to retain the favor of the people of Rome; but being at length supplanted by Anfossi, he retired to Naples, where he received a cordial welcome, and in 1776 visited Paris for the purpose of writing for the French opera. Gluck, whose *Iphigenia in Aulide* had just been produced with great success, was the reigning favorite of the hour, and Marmontel and other partisans of Italian music, who were opposed to the new ideas of the German composer, supported Piccini, then in the zenith of his fame, with all their influence. The next 3 years are famous in musical annals as the period of the celebrated war between the "Gluckists" and the "Piccinists," during which Paris was convulsed as if by a political revolution. Marmontel modernized Quinault's drama of *Roland*, and with infinite labor went over the whole work, word by word, and passage by passage, with Piccini, who was totally ignorant of the French language. The composer, whose facility was attested by the production previous to this time of the enormous number of 300 operas, found little difficulty in setting the words to appropriate music, and, after a twelvemonth of delays and difficulties of all kinds, *Roland* was performed with complete success. Piccini next produced *Atys* and *Iphigénie en Tauride*, and remained in France until 1791, when, having been deprived of his pensions and employments in consequence of the revolution, he returned to Naples. The imprudent expression of the political opinions he had imbibed in Paris led to his arrest and disgrace, and in 1798 he returned to Paris poor and enfeebled in health. With much difficulty he succeeded in procuring from Bonaparte, then first consul, the post of inspector of music at the national conservatory in Paris, which he held at the time of his death. As a musician Piccini is distinguished for the purity and simplicity of his style, and for his efforts to preserve the supremacy of the voice in operatic compositions.

PICCOLOMINI, a celebrated family of Italy, which came originally from Rome, afterward settled in Sienna, and subsequently obtained possession of the duchy of Amalfi. The most conspicuous members of this family are the following. I. Æneas Sylvius, who became pope under the title of Pius II. (See Æneas Sylvius.) II. Alessandro, archbishop of Patras, born in Sienna about 1508, died there, March 12, 1578. He wrote numerous works on natural philosophy, mathematics, astronomy, and philosophy, and composed several successful dramas. In private character he was not blameless, but he was a man of great charity, especially to needy men of letters. He was one of the first to employ the Italian language in philosophical works. III. Francesco, born in 1520, died in Sienna in 1604. He was a follower of Plato, and taught philosophy for 22 years in Sienna, Perugia, and Padua. He wrote *Universa Philosophia de Moribus* (fol., Venice, 1583) and "Commentaries upon Aristotle" (4to., Mentz, 1608). Sienna upon his death went into mourning. IV. Ottavio, duke of Amalfi, an Austrian general, born in 1599, died in Vienna in 1656. At an early age he entered the Spanish service, and afterward went to Germany as captain of horse in a regiment which the duke of Florence had sent to the assistance of the emperor Ferdinand II. against the Bohemians. In the battle of Lützen he commanded the cavalry regiment in an encounter with which Gustavus Adolphus lost his life. He was treated with great favor by Wallenstein, but when that general meditated treason he informed the emperor of the plot, and was ordered by Ferdinand to capture Wallenstein dead or alive. Before he could execute this command Wallenstein was assassinated by other hands, but Piccolomini received part of his estate. During the remainder of the 30 years' war he held important commands against the Swedes. In 1635 he was sent with a body of troops to act in the service of the king of Spain, and drove the French from the Netherlands, but was less successful against the Dutch. His victories over the Swedes led Philip IV. of Spain to ask his services, and he fought a second time with advantage at the head of the Spanish forces against the French and Dutch. In 1648 he was recalled and made marshal. After the peace of Westphalia he was sent to the convention of Nuremberg (1649), with full powers, and subsequently was raised to the dignity of prince of the empire. He was childless, and his son Max, spoken of in Schiller's "Wallenstein," is a poetic fiction.

PICHEGRU, Charles, a French soldier, born at Arbois, Franche Comté, Feb. 16, 1761, died in Paris, April 6, 1804. At the age of 16 he became a tutor in the military school at Brienne, where Napoleon Bonaparte was then a student. He soon enlisted in the army, served in the American war, and was on the eve of promotion when the revolution broke out. Returning to his native province, he became president of the democratic club at Besançon, was elected commander of a battalion of volunteers, joined the army on the Rhine, became staff officer in 1792, soon rose to the rank of brigadier general and then of general of division, and in Oct. 1793 was promoted to the chief command of that army. Having only raw recruits to oppose to the well trained troops of Austria, he conducted the campaign by skirmishing and surprises with tolerable success. In 1794, through the influence of St. Just, he was placed at the head of the army of the north, perhaps the worst clad and least cared for, but the most heroic of French troops. Rather by the energy of his soldiers and subordinate officers than his tactics, he worsted the enemy at Menin (April 13), Turcoing (May 18), and Hooglede (June 10), crossed the left bank of the lower Rhine, drove back the English and Dutch, entered the city of Amsterdam, Jan. 20, 1795, and organized the "Batavian republic." Sent back to the army on the Rhine and disgusted with the revolutionary government of France, he listened to proposals from the prince of Condé to bring about a restoration of the monarchy; he was promised in the name of the future king 1,000,000 francs and an income of 200,000 francs per annum, the duchy of Arbois, the castle of Chambord, and the governorship of Alsace. He now permitted his troops to be worsted by the Austrians; but the suspicions of the directory being aroused, he was recalled to Paris in 1796 and deprived of his command. The next year he succeeded in being elected to the council of 500, was made its president, and became the acknowledged head of the reactionary party, which openly aimed at the restoration of the Bourbons. On the 18th Fructidor (Sept. 4, 1797) he was arrested with a number of his adherents, sentenced to transportation, and banished to Sinnimari, Guiana. Thence he escaped with many perils, repaired to London, and then to Germany, always devising plans for the overthrow of the French republic. Returning to London, he became acquainted with Georges Cadoudal, in concert with whom he planned the assassination of the first consul. Both secretly repaired to Paris in 1804; but the police was on its guard; Georges was arrested in the street, and Pichegru was betrayed for a bribe by a friend, and incarcerated in the Temple. A few days later he was found dead in his cell. It was rumored that he had been despatched by order of Bonaparte; but the probability is that he strangled himself in despair. A bronze statue that had been erected in his honor on a square at Besançon under the restoration, was destroyed by the people in 1830.

PICHINCHA, a volcano of the Cordilleras of South America, near Quito in Ecuador, 14,940 feet in height. It has two peaks, the principal of which, called in the Quichua language Guagua-Pichincha, is covered with snow; the lesser is called Ruco-Pichincha; the two designations meaning the old and the young Pichincha.

PICKAWAY, a central co. of Ohio, intersected by the Scioto river, and drained by Darby, Deer, and Walnut creeks; area, about 500 sq. m.; pop. in 1860, 23,469. It has a level surface and a very fertile soil. The productions in 1850 were 2,672,905 bushels of Indian corn, 144,377 of wheat, 55,494 of oats, 131,261 of potatoes, and 73,989 lbs. of wool. There were 6 grist mills, 2 saw mills, 3 woollen factories, 8 tanneries, 4 newspaper offices, 47 churches, and 6,625 pupils attending public schools. It is intersected by the Ohio canal, and by the Cincinnati, Wilmington, and Zanesville railroad, which passes through the capital, Circleville.

PICKENS. I. A N.W. district of S. C., bordering on N. C. and Ga., bounded N. E. by the Saluda, S. W. by the Tugaloo, and N. W. by the Chattooga river, and drained by the Kiowee river and its branches and other small streams; area, about 1,100 sq. m.; pop. in 1850, 17,004, of whom 3,079 were slaves; whites in 1860, 15,335; slaves, 4,195. Its surface is uneven, the Blue ridge extending along the N. and N. W. border. Table rock in the N. is stated to be 4,000 feet high. Much of the soil is fertile. The productions in 1850 were 634,011 bushels of Indian corn, 42,052 of wheat, 125,406 of oats, 102,886 of sweet potatoes, 28,044 lbs. of rice, 19,427 of wool, and 1,357 bales of cotton. There were 2 grist mills, 7 saw mills, 12 distilleries, 4 tanneries, 1 newspaper office, 54 churches, and 355 pupils attending public schools. Capital, Pickens Court House. II. A W. co. of Ala., bordering on Miss., and drained by the Tombigbee and its branches; area, about 1,050 sq. m.; pop. in 1860, 22,319, of whom 12,192 were slaves. Its surface is uneven and the soil generally fertile. The productions in 1850 were 868,705 bushels of Indian corn, 157,537 of sweet potatoes, 32,612 lbs. of rice, and 12,905 bales of cotton. There were 3 grist mills, 8 saw mills, 3 tanneries, 2 weekly newspapers, 44 churches, and 718 pupils in public schools. Capital, Carrollton.

PICKENS. I. Andrew, an American general and statesman, born in Bucks co., Penn., Sept. 19, 1739, died in Hopewell, Pickens district, S. C., Oct. 11, 1817. His family removed to South Carolina in his boyhood and settled in a frontier region. In 1761 he served as a volunteer with Moultrie and Marion in the successful expedition led by Col. Grant against the Cherokees; and at the outbreak of the revolution he declared in favor of the colonists and was made a captain of militia, from which position he rose by regular promotion to the rank of brigadier-general. With Marion and Sumter he kept the field at the head of a partisan corps after the state had been overrun by the British. In 1781 he led an expedition against the Cherokees, whom he completely subdued in a brief campaign, by which South Carolina obtained a large cession of territory now constituting a portion of the state of Georgia; and soon after he defeated and dispersed a large body of loyalists, under Col. Boyd, at Kettle creek. At the battle of Cowpens he commanded the militia. For his conduct on this occasion congress voted him a sword. His next important service was the investment of the British forts at Augusta, Ga., which after a siege of two weeks surrendered. After participating in the unsuccessful siege of Ninety-six under Gen. Greene, he followed the retreating enemy toward the seaboard, and at the battle of Eutaw Springs led one of the brigades of the South Carolina militia, Marion commanding the other. Here he received a severe wound in the breast from a musket ball. He was subsequently engaged in the negotiation of a treaty with the Cherokees at Hopewell, and soon after settled at Hopewell, was elected to the legislature, and became a member of the convention by which the constitution of the state was adopted. He held his seat in the legislature until 1794, when he was chosen a member of congress; subsequently served again in the state legislature; and in 1801 retired from public life, reappearing for a brief period in 1812. II. Francis W., an American statesman, grandson of the preceding, born in Toogadoo, St. Paul's parish, S. C., April 7, 1807. His father, Andrew Pickens, a lawyer of wealth and ability, was governor of the state in 1816–'18. The son was educated at the South Carolina college, Columbia, and was in 1829 admitted to the bar, and commenced practice in Edgefield district. In 1832, during the height of the nullification excitement, he was elected to the legislature by the nullifiers of his district, and soon distinguished himself as a debater. At the age of 25 he was a prominent member of the judiciary committee and the committee on foreign relations; and as chairman of a subcommittee appointed in 1833 to consider the relations of sovereignty and allegiance, he made a report to the effect that sovereignty was a thing indivisible, and consequently allegiance was indivisible also. Congress, as the agent and mere creature of the states severally, had no claim to allegiance and could exercise no sovereignty, the latter doctrine resulting directly from the former. In 1834 he was elected to congress, of which he remained a member during the next 10 years. In 1836 he made an elaborate speech denying the right of congress to abolish slavery in the district of Columbia without the consent of Maryland and Virginia. In 1844 he declined a reëlection to congress, and was elected to the South Carolina senate from Edgefield. The "Bluffton movement," a demonstration on the part of certain citizens of the state to secede from the federal Union, was then in progress, and was advocated by Mr. Hammond, then governor of the state, and other prominent men. Mr. Pickens voted with the majority against the measure. After remaining several years in private life, he was elected a delegate to the Nashville southern convention which met in 1850–'51 to consider the proper course to be pursued by the South under the alleged aggressions of the North. In 1854 he presided over the South Carolina state convention called to elect delegates to the next general democratic convention, and in 1856 he went to Cincinnati as a delegate to that convention. In 1857 he was appointed by Mr. Buchanan minister to Russia, and upon his return from that country in the latter part of 1860, before the state had declared its secession from the Union, he was elected governor of South Carolina, which position he still holds (1861). Mr. Pickens is a planter of great wealth, and has devoted much attention to the scientific pursuit of agriculture. As an orator before colleges and literary societies he enjoys a considerable reputation in the southern states, and for many years he has been collecting materials for a political history of the country during the period he has been in public life.

PICKEREL. See Pike.

PICKERING. I. Timothy, an American soldier and statesman, born in Salem, Mass., July 17, 1745, died there, Jan. 29, 1829. He was graduated at Harvard college in 1763, and soon afterward became a clerk to John Higginson, register of deeds for the county of Essex. In 1768 he was admitted to the bar. From 1770 to 1777 he served, at different times, in most of the municipal offices in Salem, and on the committees of correspondence, inspection, and safety. In Aug. 1774, he with other members of the committee of correspondence was arrested at the instance of Gov. Gage, for calling a town meeting on public grievances; but in September the magistrate who had issued the warrant for the arrest recalled it, being alarmed by the unpopularity of his act. In 1775 Mr. Pickering was appointed one of the judges of the court of common pleas for the county of Essex, and sole judge of the prize court for the middle district, composed of Suffolk, Essex, and Middlesex. Impressed with the importance of calling the attention of the public to military instruction and discipline, he wrote essays on the subject for the newspaper, and published in 1775 "An Easy Plan of Discipline for a Militia," which was ordered by the legislature of Massachusetts (May 1, 1776) to be used by the militia of the colony. In the autumn of 1776, the army under Gen. Washington being greatly reduced in numbers, a large reënforcement of militia was called for, and Mr. Pickering, who then held a commission as colonel, took the command of the regiment of 700 men furnished from the county of Essex. On this tour of duty, which terminated in March, 1777, at

Boundbrook, N. J., he had interviews with Gen. Washington, and in May he was invited by him to take the office of adjutant-general, which he at first declined, but afterward accepted. In this capacity he was with Washington in the battles of Brandywine and Germantown. In November congress elected him a member of the continental board of war, in which office he served until Aug. 5, 1780, when congress, by a unanimous vote, elected him quartermaster-general, as successor to Gen. Greene. He continued in this station until July 25, 1785, when the office was abolished. He was present during the siege of Yorktown in 1781, and at the surrender of Lord Cornwallis. On the return of peace he engaged in business in Philadelphia as a commission merchant. In 1786, having been invited to assist in composing the controversy between the state of Pennsylvania and certain emigrants from Connecticut who had settled an extensive tract of land in the valley of Wyoming, which they claimed as falling within the charter limits of Connecticut, and at the same time to organize the new county of Luzerne, embracing the territory in dispute, he removed to Wilkesbarre, with the understanding that he was authorized to give assurances that the legislature would quiet in their possessions a certain class of the Connecticut settlers. An act was passed accordingly, and his efforts as a peacemaker promised a successful result; but the legislature proved inconstant, and by first suspending, and then repealing the act, increased the acrimony and strength of the discontented settlers. Their leader, John Franklin, having been arrested for high treason, some of his adherents, with the hope of obtaining his release, retaliated on Col. Pickering, in the summer of 1788, by entering his house at night, and carrying him into the woods, where they detained him a prisoner for 19 days. An interesting account of the controversy and of his captivity is contained in his letter of Dec. 31, 1818, to his son Henry, printed in Hazard's "Register of Pennsylvania," vol. vii. In 1787 he was the delegate from Luzerne co. to the Pennsylvania convention for acting upon the proposed constitution of the United States, and was earnestly in favor of its adoption. In 1789 he was the delegate from the same county to the convention for revising the constitution of Pennsylvania. Under appointments from President Washington, he made satisfactory treaties with the Six Nations collectively, and with some of them severally, in 1790, '91, and '94; and in 1793 he was joined with Gen. Lincoln and Beverley Randolph in a commission to negotiate with the hostile Indians N. W. of the Ohio; but the manœuvres of Simcoe, governor of Canada, prevented a meeting with those tribes. In 1792 he returned with his family to Philadelphia, having in August of the preceding year been appointed postmaster-general. On Jan. 2, 1795, he was transferred to the office of secretary of war, and on Dec. 12 to that of secretary of state. This position he held during the remainder of Washington's administration, and for more than 3 years under President Adams, who removed him from office May 12, 1800. He now retired to his wild lands in Pennsylvania, with the intention of bringing a portion of them into cultivation; but his friends in Massachusetts joined in the purchase of a large proportion of his lands, in order to enable and induce him to return to his native state. In 1801 he removed to Massachusetts, and subsequently purchased a farm in Wenham, near Salem. He was fond of agricultural occupations and experiments, and cultivated his grounds partly with his own hands. Later in life he was president of the Essex agricultural society. In 1802 he was appointed chief justice of the court of common pleas for the county of Essex. In 1803 the legislature elected him a senator in congress for the residue of the term of Dwight Foster, who had resigned; and in 1805 he was reëlected for the term of 6 years. After the commencement of hostilities against Great Britain in 1812, he was appointed a member of the Massachusetts board of war. From 1813 to 1817 he was a member of the U. S. house of representatives. In politics he was a federalist, and ardently opposed to some of the leading measures of the administrations of Jefferson and Madison. In religion he was a Unitarian. He published several addresses and reports, and a "Review of the Correspondence between John Adams and William Cunningham," and contributed to various periodicals. II. JOHN, an American scholar, philologist, and jurist, son of the preceding, born in Salem, Mass., Feb. 7, 1777, died May 5, 1846. He was graduated at Harvard college in 1796, and soon afterward began to study law. In 1797 he was appointed secretary of legation under William L. Smith, American minister to Portugal, with whom he remained until the autumn of 1799, when he went to London as private secretary to Rufus King, American minister at the court of St. James. In 1801 he returned to Salem, and was admitted to the bar in 1804. In 1827 he removed to Boston, and in 1829 was appointed city solicitor, which office he held until a short time before his decease. In different years he was a representative from Salem in the legislature of Massachusetts, a senator from the counties of Essex and Suffolk, and a member of the executive council. In 1806 he was chosen Hancock professor of Hebrew and other oriental languages in Harvard college, but declined the office. He received the degree of LL.D. from Bowdoin college in 1822, and from Harvard college in 1835. He was a member of the board of overseers of Harvard college from 1818 to 1824, president of the American academy of arts and sciences, originator and first president of the American oriental society, and a member of many scientific and literary societies in Europe. Although constantly engaged in his professional duties, he made large acquisitions in history and philology. In 1820 he communicated to the American academy a scheme for reducing spoken languages to written forms, in an "Essay on a Uniform Orthography for the Indian Languages of North America." He proposed that each elementary sound should be represented by its own distinctive character exclusively, and presented an alphabet formed upon this principle. The system has been applied to the Indian languages of North America and of the islands of the Pacific, and some of those of Africa. The results of Mr. Pickering's studies were for the most part made public in pamphlets or in literary periodicals. In 1816 he published his "Vocabulary of Americanisms" (8vo., Boston). Under the directions of the legislature of Massachusetts, he, in conjunction with Charles Jackson and Asahel Stearns, revised the general statutes of the state, reducing them to a code, which, as modified and adopted by the legislature, was published in 1836. His most important work was his Greek and English lexicon, which he began to prepare in 1814 (before any similar lexicon had been undertaken), and finished with the assistance of Dr. Daniel Oliver and published in 1826. A 2d edition, much enlarged and improved. appeared in 1829; and the revision of the 3d, still further improved, was completed by him just before his decease. Among his other writings separately published may be mentioned "Remarks on the Indian Languages of North America" (8vo., Philadelphia, 1836), and "Memoir on the Language and Inhabitants of Lord North's Island" (4to., Cambridge, 1845). III. CHARLES, M.D., an American naturalist, grandson of Timothy Pickering, born in Susquehanna co., Penn., in Nov. 1805. He was educated at Harvard college in the class of 1823, and was attached as naturalist to the U. S. exploring expedition under Commander Charles Wilkes, 1838–'42. After the termination of that expedition he went to India and eastern Africa, for the purpose of studying the characteristics of different tribes of those countries, and published the results of his researches in his "Races of Man and their Geographical Distribution" (4to., Philadelphia, 1848), and "Geographical Distribution of Animals and Man" (Boston, 1854). Another work, of long study, on the geographical distribution of plants, is now (1861) in the press. It consists of a botanical description and comparison of the countries visited by the exploring expedition, and by him on his subsequent excursion to the Indian ocean. About 50 comparative floras are given, personally examined at all the principal geographical positions on the globe. From hints in ancient authors, and by comparisons and calculations from various numbers in history, he is confident that he has made the discovery that the Egyptian great year consisted of 1,540 years of 365 days each, and that the fabled phœnix was but a measure of time, being 660 years, that is, $\frac{3}{7}$ of the great year. See his "Chronological Observations on Introduced Animals and Plants" (4to., Boston).

PICKERSGILL, HENRY WILLIAM, an English portrait painter, born in 1782. In 1825 he was elected a royal academician, and since 1855 he has been librarian of the academy.—FREDERIC RICHARD, also a painter, nephew of the preceding, born in London in 1820. His first work, "The Brazen Age," in water colors, was exhibited in 1839. His works attracted little attention until the production of his cartoon of the "Death of King Lear," for which he received a prize of £100 at the exhibition at Westminster hall in 1842. He also received one of the 3 first class prizes of £500 for his colossal oil painting of the "Burial of Harold," purchased for a similar sum by the commission appointed to examine the merits of pictures sent to the Westminster hall competition of 1847, and now placed in the new houses of parliament. In 1847 he was elected an associate of the royal academy, and in 1857 an academician.

PICKETT, ALBERT JAMES, an American historian, born in Anson co., N. C., Aug. 13, 1810, died in Montgomery, Ala., Oct. 28, 1858. He went with his father to Alabama in 1818, and studied law. He never applied for a license to practise, however, but after his marriage in 1832 devoted himself to literary pursuits and the care of his plantation. In 1851 he published a "History of Alabama" (2 vols. small 4to., Charleston).

PICKLES, vegetables of various sorts, as small cucumbers, onions, string beans, and cabbage, and also some fruits, such as melons, peaches, India mangoes, and soft unripe nuts, preserved in vinegar to be eaten as a condiment. The articles are steeped or parboiled in brine and then transferred to the vinegar, to which some salt is added, and to give flavor some of a variety of spices are also introduced, as well as mustard, horse radish, &c. East India pickles are flavored with curry powder mixed with mustard and garlic. For some articles the vinegar is used cold, for others hot, and for onions pure distilled vinegar is employed in order that the natural whiteness of these vegetables may be preserved. The use of pickles is so general that they are almost one of the common necessaries of life; and among seafaring men especially their consumption is said to be prodigious. On this account it is a matter of serious consideration, that they are often contaminated with a poisonous salt of copper, which after several receipts given in the cookery books is intentionally introduced for the purpose of giving to the pickles a pleasing bright green color. To obtain this effect the vinegar is boiled in brass or copper vessels, or copper coins are introduced into the boiling liquid, and sometimes verdigris and blue vitriol or the sulphate of copper. This salt is, however, produced by boiling vinegar which contains sulphuric acid in copper vessels, and most of the vinegar that is used in the pickle factories is of this character. Dr. Hassall reports that the samples of pickles examined by him, amounting to 25 in number, all contained copper to some extent, and two or three of them in dangerous quantities. Sulphuric acid also was detected in 19 out of 90 samples of vinegar used for pickling. Numerous fatal cases of poisoning are reported as having occurred from the use of such pickles. The presence of copper may be suspected in all pickles of a brighter green color than the vegetables naturally possess; and it is proved when a bright piece of iron immersed for a short time in the liquid becomes coated with copper; or if, when a bit of the pickles is minced fine and put into a vial with liquid ammonia diluted with an equal amount of water, the liquid becomes blue, it is owing to the presence of copper.

PICO DELLA MIRANDOLA. See MIRANDOLA.

PICRIC ACID. See CARBAZOTIC ACID.

PICTOU, a N. E. co. of Nova Scotia, bordering on Northumberland strait, and drained by several small rivers; area, 845 sq. m.; pop. in 1851, 25,593. Its surface is very much diversified and the soil fertile. It contains extensive mines of coal.—PICTOU, the capital, is situated on the N. shore of an extensive harbor, near the E. end of Northumberland strait, in lat. 45° N., long. 63° 10′ W., 64 m. N. E. from Halifax; pop. about 2,500. The houses are principally built of wood, and there is a neat church, an academy in connection with the Presbyterian church, a grammar school, a library, and a lighthouse at the S. side of the entrance to the harbor. Pictou is a place of rising importance, and has increased very much since the coal mines and quarries of building stone were opened in the neighborhood. Ship building is carried on; and in 1859, 49 vessels of an aggregate of 10,169 tons belonged to the port. The exports consist chiefly of coal, building stone, dried fish, and potatoes. During the year ending Sept. 30, 1859, 105,528 tons of coal were shipped; and the value of the imports was $80,446. In the same year 866 vessels of an aggregate of 64,128 tons cleared from Pictou for ports in the United States.

PICTS, an ancient people of North Britain, inhabiting the eastern coast and lowlands of Scotland. They are first mentioned in a speech of the rhetorician Eumenius, A. D. 296, to the emperor Constantius Chlorus on his return from the victory over Allectus. After this they are frequently spoken of by Roman historians, and Ammianus Marcellinus in the annals of A. D. 368 says that they were divided into the Dicalidonæ and Vecturiones. According to the account of the Scottish historians, they were brought in 843 under the dominion of Kenneth II., who thus for the first time made all Scotland subject to one king. Their name of Picti (painted) is supposed to have been derived from their custom of painting their bodies. It has been a subject of dispute whether they were of Celtic or Teutonic descent, the latter opinion being maintained by Usher, Stillingfleet, and Pinkerton, the former by Camden, Bishop Lloyd, Father Innes, George Chalmers, and Ritson. Their language bore some resemblance to the Welsh, and it was the opinion of Camden that the modern Welsh are of Pictish origin. Architectural remains of a singular character still exist in various parts of Scotland, and are there popularly called Picts' houses; and traditions of a people of that name of uncommon bodily strength have survived to this day.

PICTS' WORK DITCH. See CATRAIL.

PIEDMONT (Ital. *piè di monte*, foot of the mountain), a division in the N. W. of Italy, no longer having a distinct political existence, bounded N. by Switzerland, E. by Lombardy and Parma, S. by Genoa, and W. by France; area, 11,393 sq. m. It is enclosed on 3 sides by a stupendous mountain barrier, and opens on the 4th toward the rest of Italy. It is completely drained by the Po and its tributaries, of which there are 28 on the right bank and 25 on the left. In the intense heat of summer the ground of the plains toward Lombardy becomes so scorched that crops are only saved by a system of irrigation which is developed to great perfection. Some half a million acres are scored with artificial channels; for the privilege of using the water a tax is levied. Thus districts once waste and occupied by a scanty and impoverished population have been reclaimed and are now the granary of the old Sardinian states. Maize and barley are extensively raised; the former is the chief article of food, and the latter is fed to swine. Tobacco being a royal monopoly, its cultivation is strictly prohibited. The silk of Piedmont is the best in Italy, and its silk manufactures are important. Common linens, woollens, and cottons, hosiery, paper, leather, cutlery, beer and other liquors, glass, and iron are manufactured.—Piedmont first took a place in history under the reign of Tommaso I. of Savoy (1188-1233). It has constantly shared the fortunes of that house, during the many wars in which it has borne a part in Italy and Europe. It became a principality in 1424, was merged in the kingdom of Sardinia in 1718, and with Sardinia in the kingdom of Italy under Victor Emanuel in 1861.

PIERCE. I. A W. co. of Wis., bounded W. by the St. Croix and S. W. by the Mississippi, and drained by the Rush and other rivers; area, about 600 sq. m.; pop. in 1860, 4,674. It has a broken surface covered by prairie and forest, and the soil is fertile. Capital, Prescott. II. A S. E. co. of Minn., bounded S. W. by the Minnesota or St. Peter's river and Big Stone lake, and intersected by the Chippewa and Tipsinah rivers; area, about 1,625 sq. m.; pop. in 1860, 10. It has a rolling surface and fertile soil. III. A W. co. of Washington territory, having Puget sound on the W., bordered S. W. by the Nesqually river, and intersected by the Puyallup; area, about 1,500 sq. m.; pop. in 1860, 1,115. It is traversed by the Cascade mountains. Capital, Steilacoom.

PIERCE, **Franklin**, 14th president of the United States, born in Hillsborough, N. H., Nov. 23, 1804. His father, Gen. Benjamin Pierce, a native of Massachusetts, was one of the earliest settlers in the town of Hillsborough, and served as a soldier and officer throughout the revolutionary war. He was an influential democratic politician, in 1827 and 1829 was elected governor of the state, and died in 1839 at the age of 81. Franklin Pierce received his early education at the academies of Hancock and Francistown; and in 1820 he entered Bowdoin college, at Brunswick, Me. His ambition at this period was of a military cast, and he was a zealous officer in a college company of soldiers in which his future biographer, Nathaniel Hawthorne, was a private. During one of his winter vacations he taught a country school. He was graduated in 1824, and having chosen the law as a profession, became a student in the office of Judge Levi Woodbury at Portsmouth, afterward distinguished as a U. S. senator and a member of the cabinet. Pierce subsequently studied for two years in the law school at Northampton, Mass., and in the office of Judge Parker at Amherst, N. H. He was admitted to the bar in 1827, and began practice at Hillsborough. He did not at first succeed as an advocate, and his first case was a marked failure. He remarked to a friend who condoled with him: "I will try nine hundred and ninety-nine cases, if clients will continue to trust me, and, if I fail just as I have to-day, will try the thousandth. I shall live to argue cases in this court house in a manner that will mortify neither myself nor my friends." For some time politics diverted his attention from his profession. He was an ardent advocate of the election of Gen. Jackson to the presidency, and in 1829 was himself elected by the town of Hillsborough its representative in the state legislature. He served 4 years in that body, and in the last 2 years was chosen speaker, receiving three fourths of all the votes of the house. In 1833 he was elected a member of congress, where he served on the judiciary and other important committees, but did not attain to distinction in debate. He sustained Jackson's opposition to the internal improvement system, and made a speech against the bill authorizing an appropriation for the military academy at West Point, to which institution he was long opposed, though during the Mexican war he saw reason to change his opinion on that subject. On the question of slavery he sided with the South, and opposed anti-slavery measures in every shape. He remained a member of the house of representatives until 1837, when he was elected to the U. S. senate, in which he took his seat as the youngest member, having barely reached the legal age for the position. In the senate at that time were Clay, Webster, Calhoun, Benton, Buchanan, Woodbury, and Silas Wright. Mr. Hawthorne says: "With his usual tact and exquisite sense of propriety, he saw that it was not the time for him to step forward prominently on this highest theatre in the land. He beheld these great combatants doing battle before the eyes of the nation and engrossing its whole regards. There was hardly an avenue to reputation save what was occupied by one or another of those gigantic figures." He made in 1840 a speech upon revolutionary pensions, and in 1841 another on the removal of persons from office by the new whig administration, and in 1842 resigned his seat and returned to the practice of his profession at Concord, N. H., to which place he had removed from Hillsborough in 1838. He soon became distinguished as an advocate, and in 1846 President Polk offered him the post of U. S. attorney-general, which he declined. He also declined to be a candidate for governor, the nomination to which office had been given to him by a democratic state convention. He still, however, continued to manifest an interest in politics, and vigorously supported the annexation of Texas in opposition to a considerable portion of the democracy of New England. In 1847, when the state of New Hampshire was called upon to furnish troops for the Mexican war, he enrolled himself a member of one of the first volunteer companies of Concord, but did not long remain in the ranks; for on the passage by congress of the bill for the increase of the army he received the appointment of colonel of the 9th regiment, and shortly after was commissioned brigadier-general of the army. On May 27 he embarked at Newport with his command, and after a passage of 30 days arrived at Vera Cruz. Three weeks later he led his men to join the main body of the army under Gen. Scott at Puebla, which he reached Aug. 7, after several sharp engagements with guerillas on the way. In the battle of Contreras he was severely hurt by the falling of his horse, but continued during the day at the head of his brigade. In the battle of Churubusco, while leading his men against the enemy, he fell fainting from the pain of his injuries, but refused to quit the field. After the battle, the Mexican commander having opened negotiations for peace, Gen. Scott appointed Gen. Pierce one of the commissioners to arrange the terms of an armistice. The truce was of short duration, and the battles of Molino del Rey and Chapultepec followed, and soon afterward the city of Mexico capitulated. Gen. Pierce remained in the city till December, when, the war being ended, he returned home, and resigning his commission applied himself again to the practice of the law. In 1850 he was elected a member of the convention called by the people of New Hampshire to revise their state constitution, and was chosen president of the convention by an almost unanimous vote. In this position he exerted himself to procure the removal from the constitution of the tests by which Catholics are excluded from certain offices. On June 12, 1852, the democratic national convention assembled at Baltimore, and after 35 ballotings for a candidate for president of the United States, during which not a vote had been given for Gen. Pierce, the Virginia delegation brought forward his name, and on the 49th ballot he was nominated by 282 votes to 11 for all other candidates. His principal competitors were James Buchanan, Lewis Cass, William L. Marcy, and Stephen A. Douglas. At the ensuing presidential election in November he received the votes of all the states except Massachusetts, Vermont, Kentucky, and Tennessee, whose suffrages were given to Gen. Winfield Scott. Of the votes of the electoral colleges Pierce received 254 and Scott 42. In the midst of this sudden and astonishing political success the president elect was smitten with a terrible domestic calamity. On Jan. 6, 1853, while making with his family a railroad journey from Andover to Lawrence, Mass., the cars were thrown off the track and dashed against rocks, and his only child, Benjamin Pierce, a fine boy of 13, was instantly killed. In his inaugural address, March 4, 1853, President Pierce maintained that slavery is recognized by the constitution, and that the fugitive slave law is constitutional and should be strictly executed. He denounced in strong terms the agitation of the slavery question, which he thought had been settled by the compromises of 1850, and hoped that "no sectional or ambitious or fanatical excitement might again threaten the durability of our institutions, or obscure the light of our prosperity." Three days after his inauguration he appointed his cabinet as follows: William L. Marcy, secretary of state; James Guthrie, secretary of the treasury; Jefferson Davis, secretary of war; James C. Dobbin, secretary of the navy; Robert McClelland, secretary of the interior; James Campbell of Pennsylvania, postmaster-general; and Caleb Cushing, attorney-general. At an early period of his administration President Pierce was called upon to deal with a serious question respecting the boundary between the United States and Mexico, a tract of land between New Mexico and Chihuahua, called the Mesilla valley, being claimed by both countries. The dispute was finally settled by negotiation, and resulted in the acquisition by the United States of the region now known as Arizona. In 1853, under the direction of the war department, various expeditions were organized and sent out to explore the routes proposed for a railroad from the Mississippi to the Pacific, of which voluminous reports have since been published. In the same year a serious dispute with Great Britain on the subject of the fisheries was amicably settled by mutual concessions. While these negotiations were going on, much interest was excited both in the United States and in Europe by the affair of Martin Koszta. (See INGRAHAM, DUNCAN NATHANIEL.) The first congress which met during the administration of President Pierce assembled in Dec. 1853. In the following January Mr. Douglas, then chairman of the senate committee on territories, introduced a bill for the organization of two territories, to be called Kansas and Nebraska, in the region W. of Missouri and N. of the parallel of 36° 30′. By the Missouri compromise of 1820–'21 slavery had been formally and for ever excluded from this region. By the bill of Mr. Douglas, which was warmly supported by the administration, the Missouri compromise act was repealed and slavery permitted to enter these territories. In spite of the strenuous opposition of the anti-slavery members of congress, the bill became a law and received the signature of the president on the last day of May. Great excitement and indignation were aroused in the free states by this measure. It was denounced as a flagrant breach of faith, and as the violation of a compromise as sacred as the compromises of the constitution itself. Much dissatisfaction also was produced in the free states by the famous Ostend conference, at which Mr. Buchanan, U. S. minister to Great Britain, Mr. Soulé, minister to Spain, and Mr. Mason, minister to France, were present, and proposed to buy Cuba from Spain for $120,000,000, and in case of her refusal to sell the island to take it by force. A treaty was negotiated at Washington in 1854 between the United States and Great Britain, providing for commercial reciprocity between this country and the British provinces. The treaty with Japan negotiated by Commodore Perry was ratified by the senate at the same session. Two important bills were vetoed by the president, one of which made appropriations for the completion and repair of certain public works, and the other appropriated 10,000,000 acres of the public lands to the states for the relief of the indigent insane. In the spring of 1854, property belonging to American citizens at Greytown in Nicaragua having been stolen and reparation refused by the authorities, the U. S. frigate Cyane was sent there, and on July 13 the place was bombarded and most of it burned. In the following year occurred the fillibuster invasion of Nicaragua by William Walker, whose success in the autumn of 1855 appeared to establish his power, and consequently a minister sent by him to Washington was recognized by the president and diplomatic intercourse opened. In Feb. 1855, a bill that had passed congress for the payment of the French spoliation claims was vetoed by the president, who in the following month also vetoed a bill increasing the annual appropriation for the Collins line of steamers. The other important measures of the same session which received his signature were the bills to reorganize the diplomatic and consular system of the United States; to organize the court of claims; to provide a retired list for the navy; and to confer the title of lieutenant-general on Winfield Scott. At the close of 1854 and during the winter and spring of 1855 circumstances occurred which for a time seriously disturbed the harmony between the governments of the United States and Great Britain. Enlist-ments of recruits for the British army in the Crimea were made secretly in this country under the sanction of Mr. Crampton, the British minister at Washington, whose recall was therefore demanded by the president. This was refused, and the president at length dismissed not only the minister but the British consuls at New York, Philadelphia, and Cincinnati, because of their complicity in the violation of the neutrality laws. The matter was finally settled, and after a vacancy of a few months a new British legation was sent to Washington. The last two years of President Pierce's administration were marked by scenes of domestic discord and sectional dispute concerning affairs in Kansas. (See Kansas.) On Jan. 24, 1856, the president sent a message to congress in which he represented the formation of a free state government in Kansas as an act of rebellion, and justified the principles of the Kansas and Nebraska act. On June 2 of the same year the national democratic convention met at Cincinnati to nominate a candidate for president. The first ballot stood: for James Buchanan, 135; for Franklin Pierce, 122; for Stephen A. Douglas, 33; for Lewis Cass, 6. On subsequent ballots the vote for Pierce gradually diminished, and on the 17th ballot all the votes were given for Mr. Buchanan. Before the adjournment of congress in the following August, the house of representatives made an amendment to the army appropriation bill, providing that no part of the army should be employed to enforce the laws made by the territorial legislature of Kansas, until congress should have decided that it was a valid legislative assembly. The senate refused to concur in this proviso, and congress adjourned without making any provision for the support of the army. The president immediately issued a proclamation calling an extra session to convene on Aug. 21, when the army bill was passed without any proviso, and immediately afterward congress adjourned. It came together again on Dec. 1, and the president's annual message was chiefly devoted to the subject of Kansas, and in its citation of events and expressions of praise it took strong grounds against the free-state party of the country. The session closed on March 3, 1857, and on the following day the administration of President Pierce terminated, and that of James Buchanan commenced. Mr. Pierce soon afterward visited Madeira, and travelled extensively in Europe, from which he returned in 1860. On April 21, 1861, he made a speech to a mass meeting at Concord, N. H., in which he declared himself in favor of the Union against the southern confederacy, and urged the people to give to the national administration a cordial and vigorous support.—The life of Franklin Pierce, to the period of his nomination as candidate for the presidency, has been written by Nathaniel Hawthorne (Boston, 1852).

PIERCE, George Foster, D.D., one of the bishops of the Methodist Episcopal church, South, born in Greene co., Ga., Feb. 3. 1811. He was graduated at Franklin college in 1829, and afterward began to study law, but resolving to become a preacher, was admitted on trial into the Georgia conference at Macon in 1830. With the exception of the year 1834, during which he was stationed in Charleston, S. C., he labored in the regular ministry in various parts of his native state until 1838-'9, when he became first president of the Georgia female (now Wesleyan) college in Macon. While here he edited jointly with P. Pendleton the "Southern Lady's Book." In 1848 he was elected president of Emory college, Ga., and continued in that office until his election to the episcopacy at the general conference in Columbus, Ga., in 1854.

PIERER, Heinrich August, a German publisher, born in Altenburg in 1794, died May 12, 1850. In 1811 he studied medicine at Jena, and in 1813 joined the army, rose to the rank of major, and resigned in 1831. He took charge of his father's publishing house in 1835, and completed the *Encyklopädisches Wörterbuch* (26 vols., Altenburg, 1824–'36), commenced by his father, and afterward published a new edition, entirely recast (1840–'46). His two sons, Victor and Eugene, continued in the management of the establishment, and published a 3d edition of the encyclopedia under the title of *Universal Lexikon* (20 vols., Altenburg, 1849–'54). A 4th edition commenced in 1857 is not yet completed.

PIERPONT, John, an American poet and clergyman, born in Litchfield, Conn., April 6, 1785. He was graduated at Yale college in 1804, and in 1805 went to South Carolina as private tutor in the family of Col. William Allston. He remained there 4 years, spending part of his time in Charleston and part on the Waccamaw near Georgetown. Returning to Connecticut in 1809, he studied law in the school at Litchfield, and having been admitted to practice at the bar of Essex co., Mass., in 1812, settled at Newburyport, where he delivered before the Washington benevolent society his poem of "The Portrait," included in the collection of his "Patriotic and Political Pieces." Relinquishing the profession of law, which, in consequence of the unsettled state of affairs caused by the war, was by no means lucrative, he went into mercantile business, first in Boston and then in Baltimore, but was unsuccessful. In 1816 he published at Baltimore "Airs of Palestine," a poem in heroic measure, and soon after began the study of theology, first by himself and subsequently in the Harvard theological school. In 1819 he was ordained minister of the Hollis street Congregational church in Boston. He spent a part of 1835–'6 in Europe, extending his travels to Constantinople and the ruins of Ephesus. He had been, both in the pulpit and out of the pulpit, an active laborer in behalf of temperance, anti-slavery, the melioration of prison discipline, and other reforms. The freedom with which he expressed his opinions, especially in regard to the temperance movements, had given rise to some feeling before his departure for Europe, and in 1838 there sprang up between himself and a portion of his parish a controversy which lasted 7 years. At the end of that time a dismissal was requested by Mr. Pierpont, who had triumphantly sustained himself against the charges of his adversaries. In 1845 he became the first pastor of the Unitarian church in Troy, N. Y., where he remained 4 years, when he accepted a call from the first Congregational church in Medford, Mass., at which place he now resides. In 1840 he published an edition of his poetical works under the title of "Airs of Palestine and other Poems." At the Litchfield centennial celebration of 1851 he delivered a long poem. Many of his poems have been called forth by circumstances connected with the moral and religious movements of the times.

PIETISM. See German Theology, vol. viii. p. 194.

PIGEON, an extensive family of rasorial birds, by some ornithologists raised into an order, characterized by a short, straight, compressed bill, with the apical half vaulted and strong, and the base comparatively weak and covered with a fleshy membrane in which the nostrils are placed; wings moderate; tarsi more or less long and robust, and the toes long, divided, and padded beneath. Most pigeons are perchers, and this family may be regarded as forming the connecting link between the gallinaceous and insessorial birds. Their geographical distribution is very extensive, species being found in every part of the world except in the frigid zones; but their favorite habitats are tropical S. Asia and the islands of the Indian archipelago. They generally nest on trees, laying 2 whitish eggs on which both sexes sit in turn; the young are covered with a thin hairy-like down, and are fed in the nest till able to fly, at first by a milky half-digested substance disgorged by the old birds. The flight is generally rapid and powerful, and capable of being long sustained, as in the carrier pigeon; in the more rasorial types the wings are shorter and rounded, and the flight is abrupt, low, and of short continuance. They are generally wild and timorous, and, with the exception of the common pigeon and turtle dove, have not been domesticated. The voice consists of a guttural cooing, at times plaintive and tender, at others harsh and unpleasant, and is mostly confined to the males in the breeding season; the colors are usually brilliant and beautifully diversified; their flesh is wholesome, nutritious, well flavored, juicy, and high-colored. In the American fauna pigeons take the place of partridges and pheasants. The family includes the sub-families *columbinæ* or pigeons proper, *treroninæ* or tree pigeons, *gourinæ* or ground pigeons, *didunculinæ* or tooth-billed pigeons, and *didinæ*, of which the dodo, already described, is the only representative.—In the *columbinæ* the bill is moderate and slender, and acute at the tip; the nostrils a longitudinal slit; wings moderate and pointed; tail of various lengths, generally rounded; tarsi short, toes long, hind one about the length of the tarsus. In the typical genus *columba* (Linn.) the prevailing color is bluish gray, of different shades, with feathers of a peculiar form and metallic lustre upon the neck; their feet are formed for walking as well as perching, and they generally seek their food upon the ground; they eat principally grains, acorns, and other nuts, and some tender leaves and plants. There are more than 30 species scattered over the globe; generally seen in pairs in summer, they collect in large flocks at the beginning of winter, sometimes migrating during the latter to milder climates; they are fond of rocky places, especially on the coasts of Great Britain, Africa, and Asia, where they build their rudely constructed nests. The common pigeon or dove, too well known to need description, is derived from the wild rock pigeon or biset (*C. livia*, Linn.); in its wild state it lives in caverns and holes in the rocks of the coast, and never in the woods or upon trees; it swarms about the Orkney islands and the Hebrides and on the rocky islands of the Mediterranean. Man substitutes an artificial dove cot for the natural cavern, in which the pigeons rear their young for his benefit; the birds, however, generally depend for support on their own exertions, and enjoy so perfect a freedom of action that they can hardly be said to be domesticated. This species may be known from the wood and ring pigeons by the 2 broad and distinct black bars across the closed wings, the white of the lower part of the back, and the broad black bar at the end of the tail. It is beyond doubt that this is the species known to the ancients, and which from time immemorial has been regarded with peculiar affection by mankind, as the emblem of gentleness, affection, and the divine love and mercy; it was the dove which was sent forth as a messenger from the ark and returned with the olive branch in its mouth, the harbinger of glad tidings; it was one of the purest sacrificial offerings under the Mosaic dispensation, and to the Christian world it has always represented the Holy Spirit descending to bless mankind; from the affectionate intercourse between the sexes, it was sacred to Venus, the heathen goddess of love, and was her constant attendant. The pigeon is interesting to the comparative physiologist from the fact, above alluded to, that the parent birds nourish the young with the curd-like contents of the crop, secreted by special glands like the milk in mammalia, with this remarkable difference, that it is secreted by both sexes, and even most abundantly by the male. It was discovered by Hunter that the crop, thin and membranous in the ordinary condition, becomes thickened and enlarged in the breeding season, more vascular, with an irregular glandular appearance on the interior; the secretion of these glandulæ soon coagulates into a granulated white curd, so that the old joke about "pigeon's milk" is not without foundation; a young pigeon, like a young mammal, will surely die if deprived of its parents in the first week of its life. Pigeons do not drink in the manner of ordinary birds, but by a long, continuous draught, without raising the head until the thirst is satisfied, like cattle. There are numerous varieties or breeds highly prized by the pigeon fancier; whatever their form, colors, or peculiarities, they have all originated from a few accidental varieties of the common species, isolated and carefully bred by man, and not from hybrid crossings with other species either allied or remote; these varieties, as far as known, are permanent when bred in and in, and, if permitted to breed indiscriminately with each other, produce a fertile offspring. Such varieties require the utmost care to keep them from degenerating, and have so far lost their natural instincts and desire for liberty that they have become nearly dependent on man for their support, having in great measure lost the faculty of providing for themselves. Among the numerous varieties of this species may be mentioned the fantail, Jacobine, pouter, tumbler, and carrier pigeon, the last of which has been described under that title. The fantails are so called from the great number of the tail feathers, their erectile power and singular trembling motion; they are of small size, awkward fliers, and very apt to be overset by the wind; when pure the color is generally white, sometimes with a black head and tail. The Jacobine pigeon has a ruff of raised feathers forming a kind of hood like that of a monk; it is small, but of light and elegant form, with white head, wings, and tail, and reddish brown hood, back, and breast; some highly prized varieties are pure white; it is very prolific, a poor flier on account of its hood, and generally keeps much at home. The pouter or cropper is so called from its faculty of inflating the œsophagus to an extent sometimes equal to the size of the body; this inflation subjects the bird to many inconveniences, diseases, and fatal accidents, and hence, though of handsome plumage, it is not much esteemed by fanciers; it is also unproductive; the prevailing color is reddish brown. The tumbler is so called from its singular habit of rolling over and over in the air before alighting; the Turkish pigeon, of the same race as the carrier, is of large size, with a bill tuberculated at the base, and the eyes widely surrounded by naked red skin. The cushat or ring pigeon (*C. palumbus*, Linn.) is widely distributed over Europe and N. Asia and Africa, even where the winters are severe; it is an arboreal species, perching, roosting, and nesting upon trees, keeping a vigilant watch in the daytime; the eggs are 2, white, and hatched out in 17 or 20 days; 2 broods are raised in a year. It is a large species, measuring 16 or 17 inches in length; the sides of the neck are glossed with green, bounded by a patch of white which nearly meets behind, forming a half collar; the breast and abdomen purplish red, with the outer ridge of the wing and some of the greater coverts white. The wood pigeon (*C. œnas*, Linn.) is of smaller size, and of more limited distribution, found principally in well wooded districts, migrating to the south in winter; its habits resemble those of the ring pigeon; it is about 14 inches long, with an alar extent of 26; the general color is bluish gray, with the sides of the neck golden green, the fore neck and breast pale vinous, and the outer web of the secondaries and some of their coverts with a spot of black, not forming bars as in the rock pigeon. Neither of the last two species has been domesticated, and neither will breed with the rock pigeon, nor with their own species in captivity. There are several wild species of *columba* in the United States, as the band-tailed pigeon (*C. fasciata*, Say), about 15 inches in length, found from the Rocky mountains to the Pacific, and as far south as Mexico; the color above is olivaceous ashy, the head and lower parts purplish violet, a white half collar on the back of the neck, tail with a subterminal dusky band, sides of neck with golden reflections, and the bill yellow with a black tip. The red-billed pigeon (*C. flavirostris*, Wagl.), of the lower Rio Grande, is 14 inches long and 22 in alar extent; the general color is slaty blue, with the back olive, and the head and neck chocolate red; bill during life purple, yellow after death; no metallic scales on the neck. The white-headed pigeon (*C. leucocephala*, Linn.), a little smaller, inhabits the Indian and other southern Florida keys and the West Indies; the color is dark slaty blue, with the top of the head white, the sides of the neck with golden green scales, the bill purplish, iris white, and legs dark red.—The passenger pigeon (*ectopistes migratorius*, Swains.) has been described under that title. In the genus *carpophaga* (Selby), including the fruit pigeons, the bill has a large and prominent soft basal portion, beneath which the nostrils are situated; the 2d, 3d, and 4th quills nearly equal and longest; tail lengthened and generally rounded; tarsi very short, and clothed with down below the knee. There are about 30 species, found in the forests of India, Australia, and the islands of the Indian and Pacific oceans; they live on the branches of the highest trees, feeding on fruits and berries; their colors are green, yellow, and purple, with bronzed and metallic reflections. One of the handsomest of this beautiful group is the nutmeg pigeon (*C. ænea*, Selby), about 18 inches long, inhabiting India and its archipelago; the general color is a fine pale bluish gray, with golden green back, wings, and tail, and deep chestnut under tail coverts. The magnificent fruit pigeon (*C. magnifica*, Temm.) has the wing coverts spotted with bright yellow, a purplish green tinge on the breast and abdomen, and the rest of the lower parts rich yellow; in these and the allied species the metallic lustre of the plumage changes with every motion, rivalling even the hues of the humming birds. They feed on nutmegs, figs, and in Australia on the top leaves of the cabbage palm; the nutmegs are swallowed whole, the external envelope or the mace digested, and the hard nut voided not only uninjured but the better prepared for germination in the soil on which it is dropped; in this way the nutmeg has been extensively disseminated through the East Indian islands; it has been found by experiment that an artificial preparation by steeping in a lye of lime, analogous to what it undergoes in the intestines of the pigeon, is necessary to cause germination in the nutmeg. On this food the flesh becomes very fat and highly flavored. The double-crested pigeon (*lopholaimus antarcticus*, Shaw), a native of New Holland, has an occipital crest and one of loose feathers occupying the forehead and basal half of the bill; the wings are very long; the general color is pearl-gray, the crests reddish brown, the tail with a black bar; it is strictly arboreal, gregarious, living in the forests, feeding on the wild figs and the fruit of the cabbage palm. The genera *turtur* and *œna* of this sub-family will be noticed under TURTLE DOVE.—In the sub-family *treroninæ* or tree pigeons belong the genera *ptilonopus* (Swains.) and *treron* (Vieill.) or *vinago* (Cuv.); in these the bill is short, with the tips of both mandibles of nearly equal thickness, the tarsi very short and more or less feathered, and the toes divided at the base, with short and curved claws. In the genus *ptilonopus* or the turtelines the bill is slender, the wings moderate, the 3d quill the longest, and the 1st with the end suddenly narrowed for some distance, and the tail moderate and even. These showy birds are found in the tropical deep forests of India, Australia, and the Pacific islands; they are of solitary habits, feeding on fruits, especially that of the banyan. The purple-crowned turteline (*P. purpuratus*, Swains.) is about 10 inches long, of a parrot-green color above, paler on the sides; forehead and crown pale lilac bordered with yellow; middle of abdomen rich orange passing into pure yellow; under tail coverts orange; scapulars purplish blue; quills greenish black margined with yellow. In the blue-capped turteline (*P. monachus*, Swains.) the prevailing color is green, with the forehead, crown, and abdominal patch brilliant blue; line over the eyes, the chin, throat, and vent bright yellow. In the genus *treron* the bill is stout, the 2d and 3d quills nearly equal and longest, with the 3d notched on the inner web near the middle; tail rounded, or lengthened and wedge-shaped; there are about 20 species, inhabiting India and its archipelago and Africa; they are arboreal, wild, living in flocks, and feed on fruits and berries; the flight is rapid and low. These thick-billed pigeons vie with the parrots in the diversified colors of their plumage, the prevailing hues being green and yellow, with purplish and reddish patches. The aromatic vinago (*T. aromatica*, Steph.), of continental India, Java, and the neighboring islands, is of a general yellowish green color, with a mantle of rich brownish red, crown greenish gray, chin and throat yellow, wings greenish black edged with yellow, tail bluish gray with dark central band, the 2 middle feathers wholly green; this and the allied species luxuriate amid the rich foliage of the banyan and other tropical trees, whose fruits yield them a never-failing repast; their colors are so nearly those of the leaves among which they dwell, that it is very difficult to detect them; their feet resemble those of a parrot, and they climb among the branches very much like this scansorial bird.—In the *gourinæ* or ground pigeons the toes are usually long and strong, and adapted for progression on the ground; the wings generally short and rounded, and sometimes concave as in the partridges, and the legs are long; approaching as they do the gallinaceous birds in these respects, they differ from them in having, like the other doves, very short cæca; they run with great rapidity, but the flight is low and labored; the colors are more uniform and less brilliant than in the preceding sub-families, though some of the members are very handsome birds. The genus *columbina* (Spix) has a short slender bill, and lengthened rounded tail, and contains a few pretty little species from the warm parts of South America. The genus *zenaida* (Bonap.) has longer wings and a shorter tail; the species are few, and these small pigeons are chiefly confined to the West India and Galapagos islands, whence they sometimes wander to the Florida keys; they seek their food on the ground, and when alarmed fly off with a whistling noise. The Zenaida dove (*Z. amabilis*, Bonap.) is about 11 inches long and 18 in alar extent; the prevailing color above is reddish olive tinged with gray, with a purplish hue on the head and under parts; inside of wings and sides blue; quills brown, secondaries tipped with white, and the tail with a subterminal black bar. The keys skirted with mangroves used to be their favorite breeding places, hence called pigeon or dove keys; the nest is made on the ground, and more compact than is usual with pigeons; the flesh is excellent; the food consists of seeds, aromatic leaves, and berries, some of which are acrid and poisonous to man; the cooing is very soft and melancholy. The white-winged dove (*melopelia leucoptera*, Bonap.) has the orbital region naked; the color is light olive brown above, purplish on the head and neck, and bluish gray below; tail broadly tipped with white, and a broad white patch of the same on the wings; it is found in the West Indies, and from the valley of the Rio Grande southward. In the genus *chamæpelia* (Swains.) are included other small ground pigeons from South America and Africa. The scaly dove (*C. squamosa*, Temm.; *scardafella*, Bonap.) is about 8 inches long; the color is ashy olive above, and ashy white below tinged with pale violet on the breast, the dark brown margins of the feathers giving the bird a scaly appearance; it is found from the valley of the Rio Grande southward. The ground dove (*C. passerina*, Swains.) is 6¼ inches long; above grayish olive, the neck and occiput tinged with blue; lower parts and sides light purplish red, some of the feathers margined with darker; quills brownish orange, and wings marked with black, steel-blue, and violet blotches; female without the purplish red; it is found along the S. Atlantic and gulf coasts, and in Lower California. In the genus *peristera* (Swains.) the bill is very slender, and the tail moderate and rounded; there are about 20 species found in the tropical parts of South America, the West Indies, S. Africa, and the South sea islands; their flight resembles that of the partridge. The white-bellied ground dove (*P. Jamaicensis*, Swains.) is about 12 inches long; the upper plumage is pale umber brown tinged with green, the lower parts white tinged with vinous red on the breast; forehead and throat hoary white, and sides of neck vinous red with lilac purple and golden green reflections. The Key West pigeon (*P. Martinica*, Temm.; *oreopeleia*, Reich.) is often called mountain partridge in the West Indies; it is about 10¼ inches long; the upper plumage is brownish orange with a purple or coppery gloss; reddish white below, passing into pale wood brown; it is found in Florida and the West Indies. In Australia belong the genera *ocyphaps* (Gould), with long wings and tail, and an occipital crest; *petrophassa* (Gould), in the rocky and barren N. W. districts; *phaps* (Selby), very handsome birds, living like partridges; *geophaps* (Gould), and *chalcophaps* (Gould), found also in the Indian archipelago. These are generally showy birds, and have similar terrestrial habits. In the genus *calænas* (Gray), the bill is strong and much curved at the tip, wings long and pointed, and tail moderate and even; tarsi very robust; base of upper mandible covered with a wattle, and feathers of the neck long. These birds inhabit the Indian archipelago, running on the ground with great quickness, and perching on the lower branches of trees. The Nicobar pigeon (*C. Nicobarica*, Gray) is one of the most beautiful of the family in its colors, though its heavy body, pendent tail, and concave wings show its affinity with rasorial birds; it is about 15 inches long; the plumage is rich metallic green, changing with the light into golden, coppery, and purplish red; the tail is pure white, and the quills blackish blue with greenish reflections. In the genus *verrulia* (Flem.) belongs the carunculated pigeon of S. Africa (*V. carunculata*, Flem.); the bill is slender, the wings long, and the tail short; there is a pendulous wattle under the throat, and a naked hanging band on the sides of the neck; it comes in these respects the nearest to the *gallinæ*, and also, like the preceding genus, lays 6 or 8 eggs instead of the usual 2 of the pigeons, and the young immediately follow their parents, who keep them together by a peculiar cry; the food consists of grain, berries, and insects; the upper parts are gray, with a purple tinge on the head and neck; the under parts white, and the tail reddish brown. In the genus *starnænas* (Bonap.) belongs the blue-headed pigeon (*S. cyanocephala*, Bonap.) of the West Indies and the southern keys; above and on the sides the color is olivaceous chocolate, and below reddish brown; chin, throat, and forehead black; crown blue; it is about 10¾ inches long; it is retired and solitary, and lays several eggs in a nest on the ground; the young are said to follow the parents as soon as hatched. In the genus *goura* (Flem.) belong the large crowned pigeons of New Guinea and the Indian archipelago; the head is ornamented with a large compressed crest. The crowned pigeon (*G. coronata*, Steph.) is the largest of the family, being 27 or 28 inches long; the bill is 2 inches long and black; the crest is composed of long silky barbules plumed at the end, which, with the head, neck, and lower parts, are grayish blue; back with the feathers black at the base with tips of rich purplish brown; a central broad white bar across the closed wings. This bird seems to connect the pigeons with the curassows and guans; it nests in trees, and lays only two eggs; it is readily tamed, but, like the gaudy Nicobar pigeon, does not propagate in confinement, and can hardly bear the chilly temperature of northern climates; its flesh is excellent for food. This species and the *G. Victoriæ* have hybridized at the London zoological gardens, and have produced a living young one, having sat upon a single egg for 28 days.—The sub-family *didunculinæ* have the bill strong and nearly as long as the head, with the culmen depressed close to the forehead, and then suddenly rising and forming an arch to the acute and overhanging tip; the lower mandible is armed with 3 distinct angular teeth near the truncated tip; the wings moderate and concave, and the bend armed with a blunt tubercle; the tail short and rounded; tarsi moderate and strong; all the toes long, and with sharp curved claws; bare space around eyes and on each side of throat. The only genus is *didunculus* (Peale), and the only species *D. strigirostris* (Gould), found in the Samoan islands; it is about the size of a common pigeon, of a general blackish glossy green color, with chestnut back and tail, brownish quills, and orange bill. Its wings indicate a considerable power of flight, and it is said to pass most of its time on trees, feeding on berries and fruits; it also seems adapted for movement on the ground, and its bill is suited to digging up bulbous roots or stripping the husks from nuts. They are generally seen in pairs or small flocks; the nest is made among rocks, and the young are born naked and helpless; the flesh is excellent; they are kept as pets by the natives. This is an interesting bird, as showing a living connection of the pigeons with the extinct dodo; many of its characters also bring it near gallinaceous birds, especially the curassows.

PIGEON HAWK, a small bird of prey of the falcon sub-family and genus *hypotriorchis* (Boie), which differs from *falco* (Linn.) in its longer and more slender tarsi, covered in front with large hexagonal scales, and very long and slender toes. There are more than a dozen species scattered over the world, of which the two most common European representatives have been described under Hobby and Merlin; they prefer wooded cultivated districts, and usually follow in the train of the small migratory birds on which they prey; the flight is rapid and long sustained; the nest is made on trees or among rocks, and the eggs are from 3 to 5. The American pigeon hawk (*H. columbarius*, Gray) is 12 to 14 inches long and 26 in alar extent; the male is smaller than this. The adult bird has been described by Audubon as the little corporal hawk (*F. temerarius*); its general color is bluish slate, every feather with a longitudinal black line; forehead and throat white; below pale yellowish or reddish white, each feather with a longitudinal line of brownish black; the tibiæ are light ferruginous, with black lines; quills black, with ashy white tips; tail light bluish ash, tipped with white, with a wide subterminal black band and several narrower bands of the same; cere and legs yellow, and bill bluish; the younger birds are dusky or blackish brown above, and the tail has 4 to 6 white bands; the variations in plumage, according to age and locality, are considerable. It is found over all temperate North America, Central, and the N. of South America; it breeds in the north. It is the boldest of any hawk of its size, pouncing on thrushes, wild pigeons, woodpeckers, snipe, and even teals, but preying chiefly on birds of the size of the red-winged blackbird and sora rail; it has been known to attack cage birds in the porches of houses in crowded cities. According to Dr. Brewer, the eggs measure about 1¾ by 1¼ inches, and are nearly spherical; the color is not a very clear white, and there are a few bold irregular dashes of light yellowish brown, chiefly about the smaller end; the nest is coarsely constructed of sticks and mosses, resembling that of a crow.

PIGMY, or Pygmy (Gr. πυγμαῖος, from πυγμή, the fist, or a measure extending from the elbow to the fist, equal to 13½ inches), the name of a fabled nation of dwarfs said to be only 3 spans high, and believed in by the ancients from an early date as inhabiting the interior of Africa, where they were supposed, according to Juvenal, to wage continual war with the cranes. Herodotus (ii. 32) speaks of them, and, like all who have copied him, probably confounded in his account men and the cynocephalous apes of Africa. Dr. Krapf, a missionary, has recently revived these stories with reference to the Dokos, a tribe of E. African negroes to the south of Shoa and Kaffa. (See Dokos.)—The term pigmy has in the United States been applied by some writers, ignorant of anatomy, to a race whose remains have been found in the valley of the Mississippi. The enclosures containing these bones are made of 6 pieces of rough sandstone or limestone, 18 to 24 inches long, 18 deep, and 16 wide; the bodies are placed with the shoulders and head elevated and the knees raised toward the face, in a reclining or sitting posture, with various ornaments and cooking utensils; the total length of the skeletons has been from 3 to 4½ feet. According to Dr. S. G. Morton, the separable condition of the cranial sutures, the character of the changing dentition, and the absence of union of the epiphyses of the long bones, show that these supposed pigmies were only children, from 6 to 10 years of age, of the American Indian race, whose bodies for unknown reasons were buried apart from the adults of their tribe.

PIGNEROL. See Pinerolo.

PIKA (*lagomys*, Cuv.), a genus of the family *leporidæ*, including the tailless hares. They have no visible tail, the ears are short and rounded, the hind legs short, and the molars $\frac{5-5}{5-5}$; the skull is very flat, dilated behind, the interorbital space contracted, the supraorbital processes absent, the orbits directed upward, and the malar bones extending backward nearly to the opening of the ear chamber; there is one principal opening in the nasal process of the superior maxillary bone; the zygomatic arch is remarkably short; the coronoid process of the lower jaw a mere tubercle, and the mental foramen situated near the middle of the ramus; the principal upper incisors have a deep vertical groove on the outer side, and terminate in 2 points with a notch at the end; the lower incisors simple; the upper molars as in the hares, the lower with a deeper outer groove; there are generally small naked pads at the end of the toes, the rest of the feet densely clothed with fur. The pikas are of small size, the largest not exceeding a Guinea pig; they are found only in alpine or subalpine districts, where they live in burrows or among loose stones, remaining quiet by day and feeding at night; the food consists of herbage of different kinds, which they store up in little piles in autumn for winter consumption; when feeding they often utter a chirping or whistling noise. The alpine pika (*L. alpinus*, Cuv.) is about 9½ inches long, with long and soft fur, grayish next the skin; general color above grayish brown, yellowish gray below; feet pale, with a yellowish tinge; the ears margined with white; it inhabits Siberia from the river Irtish to Kamtchatka. The pigmy pika (*L. pusillus*, Desm.), from southern Siberia and the Ural mountains, is 6¾ inches long, of a general brownish tint pencilled with black and brownish yellow; feet and under parts yellowish white. Other species are found in the mountainous districts of Hindostan, some of them 6,000 or 8,000 feet above the sea. The Rocky mountain pika (*L. princeps*, Rich.), or little chief hare, is about 7 inches long; the general color is grayish above, penciled with black and yellowish white; yellowish brown on the sides, and dirty yellowish white below. It is found along the Rocky mountains from lat. 42° to 60° N.; it frequents heaps of loose stones, coming out after sunset. Pallas describes the polar pika (*L. hyperboreus*, Wagn.), the smallest known species; it is only 5½ inches long, grayish brown above, tinged with rufous on the head and sides; it is from N. E. Siberia. There are 3 or 4 fossil species described from the osseous breccia and the pliocene of Europe.

PIKE (*esox*, Linn.), the common name of the soft-rayed abdominal fishes, whose single genus now constitutes the family *esocidæ*. Their headquarters are in North America, only one species being found in Europe and temperate Asia; they are confined to fresh water and to the northern hemisphere. The body is elongated and scaly; there is a single dorsal, generally opposite the anal; there is no adipose fin; the upper jaw is formed principally by the intermaxillaries; the mouth is large and well furnished with teeth; there are several covered glandular accessory branchiæ, the number of branchiostegal rays varying from 8 to 18; swimming bladder simple; stomach siphonal, intestine short and without cæca; under the skin are vascular ramifications, peculiar to the family. According to Agassiz, the cylindrical elongated form indicates a low position among the abdominal fishes, as also does the mouth, the maxillaries being without teeth while the palate bones are powerfully armed; the intermaxillaries and the maxillaries are in one arch, as in the salmon family; the skeleton, and especially the skull, is remarkably soft. The common pike of Europe (*E. lucius*, Linn.) rarely exceeds 3 feet in length or a weight of 12 or 20 lbs.; some have been described considerably beyond these, but most are below them; the head is elongated and flattened, the lower jaw considerably the longer; the gape very large; the head and upper back dusky brown, becoming lighter and mottled with green and yellow on the sides, passing into silvery white below; pectorals and ventrals pale brown, other fins darker, mottled with white, yellow, and green; iris yellow. Young pikes, or pickerels, are of a greenish hue, and the colors vary much at all ages. The pike inhabits most of the rivers and lakes of Europe, and was long ago introduced into Great Britain, where it is now exceedingly common; from the 13th to the 15th century it was so rare in England that the price was fixed by law, and generally a much higher one than for salmon or turbot. The pike is a very strong, active, and fierce fish; it darts from its reedy cover with extreme velocity, swallowing other fish, water rats, and even small aquatic birds; Lacépède calls it the shark of the fresh waters, sparing not its own species and devouring its own young, and tearing in its gluttonous fury even the remains of decomposing carcasses. Its size, strength, swiftness, and daring render it a tyrant dreaded by all the inhabitants of lake and river. Wonderful stories have been told regarding the gigantic size and extreme longevity of the pike, and we can readily conceive that it may attain a weight of 40 or 50 lbs. and an age of 100 years, where food is abundant and anglers absent. Its flesh is well flavored and easy of digestion. Cuvier, Richardson, and others have asserted that this species occurs also in the great American lakes; but on the general principle that the animals of America and Europe, with the exception of the arctic fauna, though nearly allied, have not been found to be identical species, this may be reasonably doubted; the fish described from America as *E. lucius* is probably the first of the species noticed below, or else one of the many as yet undescribed.—The common lake pike of America (*E. estor*, Lesueur) attains a length of 3 feet; the back is deep greenish brown, the sides with numerous rounded and oblong pale yellowish spots, and the abdomen white; the fins are reddish yellow, marbled with blackish and deep green, the caudal large and lunated; it is found in the great northern lakes. The muscalonge or maskinonge (*E. nobilior*, Thompson) of Lake Champlain is a larger and rarer fish, and much better for the table, always commanding a higher price than the lake pickerel, though the latter is often erroneously called muscalonge; the lower half of the cheek is without scales, which is not the case in *E. estor*. Mr. Thompson (in his appendix to the "History of Vermont," 1853) spells the name *masquallonge*, deriving it from *masque* (face) and *allongé* (elongated), an epithet given to it and other pikes by the French Canadians. This may be distinguished from the lake pickerel by the nearly black color of the back, the bluish gray sides with dark brown rounded markings, its grayish white abdomen tinged with ruddy, its more robust proportions, shorter head, flatter face, and wider jaws; it attains a length of more than 4 feet and a weight of 40 lbs. Agassiz describes a pike of large size from Lake Superior, in his narrative, under the name of *E. boreus*. The common pike of the northern states, the long or shovel-nosed pickerel (*E. reticulatus*, Lesueur), attains a length of 1 to 2 feet; the colors vary in different localities, but in most the body is green above and golden yellow on the sides, with irregular dark longitudinal lines united into imperfect reticulations; lower parts white, flesh-colored on the throat; a black vertical band beneath the eye; dorsal and caudal fins greenish black, the others flesh-colored. This is everywhere valued for the table, and is caught at all seasons of the year, even through the ice; it is taken generally with a hook, baited with a frog's leg, small fish, or any white substance moved rapidly over the surface of the water; it is also speared through holes in the ice, or from boats to which it is attracted by bright lights. It is a very rapid swimmer, voracious, and strong; like other species it remains apparently motionless in the water watching an opportunity to dart upon its prey, which consists of any fish which it can possibly swallow, the spiny perch in most cases excepted; while the body remains suspended, there is an incessant motion of the few last rays of the dorsal and anal fins, especially the *former*, with a rotary movement of the pectorals, and occasionally of the ventrals and caudal; these forces maintain such an exact equilibrium that the fish does not move in the water. The trout pickerel, or short-nosed pickerel (*E. fasciatus*, De Kay), is commonly somewhat smaller; the general color is dark greenish, with about 20 narrow blackish brown bands, not forming a network; the throat stained with fuliginous; the body is proportionately stouter and the snout shorter than in the preceding species. This species is found generally in the pickerel weed or in water bushes (*cephalanthus occidentalis*); it is taken at all seasons of the year, but rarely in the deep water channel like the long-nosed species; it takes the bait eagerly, and makes back into the shallow coverts whence it darted; it bites at any time of day, and whether the bait be at or beneath the surface, moving slow or fast; it is more voracious, if possible, than the *E. reticulatus*, an individual being frequently landed after having been several times drawn partly out of water; it has been known to take the hook with the tail of a half digested fish visible in its mouth. Any one who has seen pickerel dart upon fish in an aquarium, and witnessed the force with which they strike the bottom, will perceive what an admirable fender the prominent lower jaw makes; it is frequently much lacerated by violent contact with the bottom, without the upper jaw suffering at all.—The name of pike is sometimes given to the long-jawed marine fish of the allied genus *belone* (Cuv.); in this the head and body are very much elongated, the latter covered with very minute scales; the long jaws are straight, narrow, pointed, and armed with numerous small teeth. The *B. truncata* (Lesueur), called the long-jawed or gar pike, is from 1 to 2 feet long, of a light greenish color above and silvery beneath, with a dark band extending from above the pectorals to the origin of the dorsal; the body is slender, and the head flattened; the dorsal is situated on the posterior fourth of the body, highest in front and rapidly decreasing toward the caudal; the anal shaped like the dorsal, and opposite to it. It is found in the southern New England and the middle states. The European sea pike (*B. vulgaris*, Cuv.), or mackerel guide, so called from its preceding the latter to shallow water to spawn, is about 2 feet long; it is abundant on the coasts of northern Europe, and is taken in the spring; it is also used as bait; the flesh resembles that of the mackerel, but is drier, and the bones are greenish. It is an active fish, swimming near the surface, and often springs out of water. The color above is dark greenish blue, lighter on the sides, and silvery below; dorsal and caudal greenish brown, and other fins white.

PIKE, the name of counties in 10 of the United States. I. A N. E. co. of Penn., separated from N. Y. and N. J., which there form an angle, by the Delaware river, and drained by Lackawaxen and Shohola creeks; area, about 600 sq. m.; pop. in 1860, 7,155. It has a rough, hilly surface, and indifferent soil, with forests that yield large quantities of timber. The productions in 1850 were 38,609 bushels of Indian corn, 16,874 of oats, 52,059 of potatoes, 3,546 of wheat, 3,519 lbs. of wool, and 90,517 of butter. There were 4 grist mills, 29 saw mills, 5 tanneries, 5 churches, and 955 pupils attending public schools. The N. part is traversed by the Delaware and Hudson canal, and the New York and Erie railroad passes along the N. E. border. Capital, Milford. II. A W. co. of Ga., bordered W. by Flint river and drained by Big Potato, Elkins, and other creeks; area, about 400 sq. m.; pop. in 1860, 10,090, of whom 4,723 were slaves. It has an uneven surface and moderately fertile soil. The productions in 1850 were 418,990 bushels of Indian corn, 46,442 of oats, 85,556 of sweet potatoes, and 8,002 bales of cotton. There were 8 grist mills, 5 saw mills, 4 tanneries, 2 newspaper offices, 28 churches, and 554 pupils attending public schools. It is intersected by the Macon and western railroad. Capital, Zebulon. III. A S. E. co. of Ala., bordered E. by Pea river, and drained by the Conecuh river and its branches; area, about 1,200 sq. m.; pop. in 1860, 24,436, of whom 6,785 were slaves. Its surface is undulating, much of it covered with pine; the soil is not very fertile. The productions in 1850 were 531,192 bushels of Indian corn, 151,657 of sweet potatoes, and 5,679 bales of cotton. There were 2 grist mills, 2 saw mills, 8 tanneries, 18 churches, and 498 pupils attending public schools. Capital, Troy. IV. A S. co. of Miss., bordering on La., and drained by Bogue Chitto river and its branches; area, about 850 sq. m.; pop. in 1860, 11,135, of whom 4,935 were slaves. The productions in 1850 were 245,751 bushels of Indian corn, 27,366 of oats, 61,040 of sweet potatoes, 290,550 lbs. of rice, and 4,128 bales of cotton. There were 6 grist mills, 7 saw mills, 2 tanneries, 15 churches, and 458 pupils attending public schools. Capital, Holmesville. V. A S. W. co. of Ark., drained by the Little Missouri river and its branches; area, about 600 sq. m.; pop. in 1860, 4,025, of whom 227 were slaves. It has a hilly surface and fertile soil. The productions in 1854 were 96,915 bushels of Indian corn, 3,756 of wheat, 5,750 of oats, and 429 bales of cotton. Capital, Murfreesborough. VI. A co. of Ky., in the extreme E. corner of the state, bordering on Va., drained by the West fork of Big Sandy river; area, 400 sq. m.; pop. in 1860, 7,384, of whom 97 were slaves. It has a hilly surface, the Cumberland mountains extending along the S. E. border and a spur partly along the S. W. There are extensive beds of bituminous coal. The productions in 1850 were 198,764 bushels of Indian corn, 2,454 of wheat, 18,501 of oats, 12,058 lbs. of wool, and 4,401 of tobacco. There were 10 churches, and 180 pupils attending public schools. Capital, Pikeville. VII. A S. co. of Ohio, intersected by the Scioto river and drained by several branches; area, about 425 sq. m.; pop. in 1860, 13,643. It has a diversified surface and fertile soil. The productions in 1850 were 797,655 bushels of Indian corn, 16,725 of wheat, 67,788 of oats, 23,475 lbs. of wool, and 121,597 of butter. There were 4 grist mills, 12 saw mills, 3 tanneries, 47 churches, and 1,478 pupils attending public schools. It is intersected by the Ohio canal. Capital, Piketon. VIII. A S. W. co. of Ind., bordered N. by White river and drained by Patoka and S. Patoka creeks; area, 337 sq. m.; pop. in 1860, 10,183. It has a gently undulating surface and a generally fertile soil. The productions in 1850 were 407,281 bushels of Indian corn, 15,128 of wheat, 27,394 of oats, 16,991 lbs. of wool, and 733 tons of hay. There were 10 grist mills, 4 saw mills, 2 tanneries, 14 churches, and 375 pupils attending public schools. It is intersected by the Wabash and Erie canal. Capital, Petersburg. IX. A W. co. of Ill., separated from Mo. on the S. W. by the Mississippi river, bounded E. by the Illinois, and drained by McKee's, Bay, and Little Muddy creeks; area, about 750 sq. m.; pop. in 1860, 27,249. A lateral channel of the Mississippi, called Snycartee slough, traverses the county. It has a rolling surface, about equally divided between forest and prairie, and the soil is very fertile. It contains large quantities of coal. The productions in 1850 were 1,375,045 bushels of Indian corn, 194,051 of wheat, 130,267 of oats, 38,450 lbs. of wool, and 119,741 of butter. There were 12 grist mills, 8 saw mills, 2 weekly newspapers, 16 churches, and 3,241 pupils attending public schools. Capital, Pittsfield. X. An E. co. of Mo., separated from Ill. by the Mississippi river, intersected by Salt river, and drained by several creeks; area, about 700 sq. m.; pop. in 1860, 18,420, of whom 4,056 were slaves. The productions in 1850 were 748,540 bushels of Indian corn, 106,241 of wheat, 85,060 of oats, 44,405 lbs. of wool, and 348,830 of tobacco. There were 17 grist mills, 8 saw mills, 6 tanneries, 2 weekly newspapers, 31 churches, and 2,730 pupils in public schools. Capital, Bowling Green.

PIKE, Albert, an American poet, born in Boston, Dec. 29, 1809. According to his own account, his father was "a journeyman shoemaker, who worked hard, paid his taxes, and gave all his children the benefit of an education." When he was 4 years old the family removed to Newburyport, and in the district schools of that town and in an academy at Framingham he received his early education. At the age of 16 he entered Harvard college; but being unable to support himself in Cambridge, he became assistant teacher and subsequently preceptor of a grammar school in Newburyport. Afterward he taught successively an academy at Fairhaven and a private school in Newburyport. In the spring of 1831 he started for the West and South. Arriving at St. Louis, after having gone much of the way on foot, he set out with a company of 40 on an expedition to Mexico, and reached Santa Fe on Nov. 28, where he remained a year, engaged part of the time as a merchant's clerk and part of the time in peddling. In Sept. 1832, he left Taos with a company of trappers, and, after a visit to the head waters of the Red and Brazos rivers, separated with 4 others from the party, travelled 500 miles on foot, and reached Fort Smith in Arkansas, "without a rag of clothing, a dollar in money, or knowing a person in the territory." The following winter he spent in teaching, and in July, 1833, he began a school, which he was soon forced to give up on account of sickness. In the mean time he had written several poems for the "Arkansas Advocate," a newspaper published at Little Rock, which so pleased the editor that he gave Pike an invitation to become his partner. The offer was gladly accepted, and in this position he remained until 1834, when he bought the whole establishment. He continued to edit the paper until 1836, but meanwhile studied law and was admitted to the bar, after which he devoted himself entirely to that profession. A little before this he had published in Boston a volume of "Prose Sketches and Poems," in which he gave an account of some of his journeys. The "Hymns to the Gods," published subsequently, were composed at an earlier period, while he was teaching school at Fairhaven. Several fugitive poems of his have also appeared in periodicals, and in 1854 a collection of his poetry, including the "Hymns to the Gods," was printed at Philadelphia under the title of "Nugæ," but was never published. Mr. Pike has been a prominent man in the political movements of the South-West, acting there with the state rights party. During the Mexican war he served with distinction as a volunteer.

PIKE, Zebulon Montgomery, an American general, born in Lamberton, N. J., Jan. 5, 1779, killed in the attack upon York (now Toronto), Canada, April 27, 1813. His father was an officer in the U. S. army, and the son, early embracing the same profession, entered his father's company, then serving on the western frontier, and rose to the rank of lieutenant. He was at the same time a diligent student, and acquired a knowledge of the Latin, French, and Spanish languages. After the United States purchased Louisiana, Pike was sent on an expedition to explore the sources of the Mississippi and the surrounding territory. He left St. Louis Aug. 9, 1805, at the head of 20 men, provisioned for 4 months; but his journey lasted nearly 9 months, during which he suffered greatly from inclement weather and scarcity of food. Two months had not passed by after his return when he was sent by Gen. Wilkinson on a similar expedition to the interior of Louisiana.

Here winter overtook the party, and for weeks they suffered from cold and hunger. At last, after 3 months' march, they made their way to what they supposed was the Red river, but were taken prisoners by a body of Spanish cavalry, who informed them that they were in Spanish territory and on the banks of the Rio Grande. After an examination before the commandant-general of the province of Biscay, Pike was released and sent home, arriving at Natchitoches July 1, 1807. He received the thanks of government, and was made successively captain, major, and in 1810 colonel of infantry. In that year he published an account of his two expeditions, illustrated by several original maps and charts. At the beginning of the war of 1812 he was stationed on the northern frontier, was appointed in 1813 brigadier-general, and was selected to command the land forces in the expedition against York, the capital of Upper Canada. He sailed from Sackett's Harbor April 25, arrived at York April 27 at the head of 1,700 men, and commenced the landing under a heavy fire. After carrying one battery he was about to assault the main works, when the British magazine exploded, and Pike was mortally wounded by a heavy stone. He was carried to the commodore's ship. In his last moments the British flag was shown him; making a sign to place it under his head, he expired.

PIKE'S PEAK, a peak of the Rocky mountains, in the territory of Colorado, lat. 39° N., long. 105° W., named in honor of Gen. Z. M. Pike, who discovered it in 1806. Its height is variously given at from 12,000 to 14,500 feet above sea level. The ascent, which is made from Colorado City, is extremely difficult, passing over rugged hills, and along the precipitous walls of narrow *cañons*, which abound in cascades and picturesque views. No route has yet (1861) been found by which horses or mules can approach from the E. within 8 miles of the base. In ascending, the transition is extremely abrupt from a dense pine forest to the bare, open mountain side, with no vegetation except beds of grass among the rocks. Near the summit, blossoms of faint yellow mingled with purple spring from the ground in great profusion, so near banks of snow that one may pluck flowers with one hand and gather snow in the other. Two enormous gorges extend from the top almost to the base, one of them visible to the naked eye at the distance of 80 miles. The summit is nearly level, embracing about 60 acres, and composed of angular slabs and blocks of coarse, disintegrating granite. It affords one of the grandest views on the North American continent, extending nearly 100 miles in all directions, embracing the great plains on the E., and on the N., S., and W. a vast expanse of mountains, of diverse forms and varying colors, including several transparent, sparkling lakes, and the sources of 4 great rivers, the Platte, Arkansas, Rio Grande, and Colorado of California. Directly W., and thousands of feet below, are the South park, a crescent-shaped section of smooth, treeless prairie, 40 miles by 16 in extent, and other fields of rich floral beauty, enclosed by rugged mountain walls. In the gorges near the summit snow is perpetual.—The mountain has furnished the popular name for the Rocky mountain gold region, not yet fully explored, but embracing portions of the original territories of Kansas, Nebraska, New Mexico, Utah, and Oregon. For many years vague reports and traditions of gold in this region had been current among trappers and Indians. In 1857 a party of civilized Cherokees made the first organized attempt to explore it, but were driven back by hostile savages. In 1858 a company from Georgia, and another from Lawrence, Kansas, reported that they had discovered gold in paying quantities in the valleys near the base of Pike's peak, though subsequent investigations have not developed any remunerative diggings within many miles of that mountain. On May 6, 1859, rich deposits of gold were found in the mountains on the head waters of Clear creek, 50 m. N. of Pike's peak; and from that day the country has been settled with great rapidity. In Aug. 1860, its population was 60,000, and two months later there were 175 quartz mills in the mountains, about one half of them in operation, at an outlay of $1,800,000. The gold yield of 1860 was estimated at $4,000,000. In the vicinity of Clear creek, near the original discoveries, quartz mining is the leading occupation, and the gold-bearing quartz is found in great abundance, while 100 m. further S. gulch mining is largely carried on. The gold is found exclusively in the mountains. Its northern limit, as far as yet discovered, is in the Wind River mountains, and its southern in the San Juan mountains of New Mexico, more than 500 m. apart; but a great portion of the intervening country has not yet been examined. Silver ore is found in large quantities W. of the South park, on both sides of the dividing ridge; but its quality has not been sufficiently tested to demonstrate the practicability of mining it. Iron, lead, coal, and other minerals have also been found. The auriferous quartz exists in lodes, running N. E. and S. W.; and the geology of the region differs radically from that of California and Australia.—The climate is healthy and agreeable, and the winters are mild, though with occasional periods of 2 or 3 days in which the cold is intense, and the mercury sometimes descends to 20° below zero. Changes of temperature are much more sudden and severe than on the Atlantic coast, but lung diseases are almost entirely unknown. The elevation of the valley regions is about 5,000 feet above the sea; the atmosphere is peculiarly clear and invigorating, and so dry that fresh meat cut in strips and exposed to it will cure sufficiently, without salting or smoking, to be carried to any part of the world. No rain falls, except during about 7 weeks of the late summer and early autumn. The mountains are densely wooded with pine, spruce, fir, cedar, and aspen.

The ascent of the dividing ridge is in many places very gentle; and near Breckinridge waters which run to the Atlantic gush from the ground within 500 yards of springs which feed a tributary of the Pacific. Several passes through the mountains have been found, which offer no engineering obstacles to the construction of a railroad so serious as those which have been already overcome in the Alleghanies. The great American desert extends to the base of the mountains, which rise abruptly like a wall on its western border. With the exception of the narrow valleys of the streams, it consists of vast wastes of sand, destitute of tree or shrub, and characterized by numerous varieties of the cactus, aspen, withered grass, stunted shrubs, and alkaline waters, often poisonous to both cattle and men. The streams sometimes sink abruptly from view, leaving a dry bed of sand above, and run underground for many miles, when they again gush up as suddenly as they disappeared. Antelopes, wolves, prairie dogs, and rattlesnakes abound in the desert, and elk and grisly and several other species of bears in the mountains. The soil of the valleys appears to consist of pure sand; but with ample irrigation it produces wheat, barley, and root crops in great abundance. Some flour is brought from New Mexico and Salt Lake, and other supplies from the Missouri river. The transportation of all the imports from 300 to 700 miles, in wagons drawn by oxen and mules, renders the expenses of living more than 100 per cent. higher than on the Missouri river. The principal tribes of Indians are the Arapahoes and Utes. The latter are sometimes hostile, but easily held in check by the whites.—The region abounds in natural features of peculiar interest, which, whenever a railway connection is obtained, must render it a popular summer resort. Among these are Pike's and Long's peaks, the North, Middle, and South parks, the Monument region, and numerous hot and cold mineral springs. The Monument region comprises a large section along Monument creek, abounding in natural stone monuments, standing upright in picturesque and fantastic forms. The predominant shape is that of gravestones, which, interspersed with numerous pine groves, give it the appearance of a great cemetery. Two miles from Colorado City they culminate in the "Garden of the Gods," or "Red Rocks," which rise perpendicularly 350 feet, forming a most impressive spectacle. At one point they have been reft asunder to the base, leaving a natural gap or carriage way. Near them are the famed boiling fountains (Fontaine qui Bouille), which gush up with great force, and are so strongly impregnated with soda that they have incrusted the adjacent rocks with deposits of it to the thickness of several inches. Flour mixed with their waters, without the addition of any other substance, forms peculiarly light bread; and they are alleged to possess rare medicinal qualities. The Indians regard these fountains with awe and reverence, as the abode of a deity who "troubles the waters." The Arapahoes formerly strewed the ground with tomahawks and knives, and hung the trees with quivers and moccasons, as propitiatory offerings to the spirit of the place.—Denver is the metropolis of the Pike's peak region, and is a well built town of 6,000 inhabitants. A bill was passed by congress in Feb. 1861, to organize the region into a territory under the name of Colorado, bounded N. by lat. 40° N., E. by long. 102° W., S. by lat. 37° N., and W. by the Green and Colorado rivers.

PILATE, Pontius, the Roman officer or ruler of Judæa under whom Christ suffered. The nature of his office is not well understood. In the Greek Testament he is called *ἡγεμων*, which King James's and the Rhemish versions translate "governor;" Philo Judæus and the Greek fathers style him *επιτροπος*; Josephus both *επιτροπος* and *ἡγεμων*, and Tacitus *procurator*. He was the 6th Roman incumbent of that office, succeeding Valerius Gratus, A. D. 25 or 26, under the reign of Tiberius, and retaining the post 10 years. Josephus relates several acts of injustice which he committed during his government, and he was finally disgraced in consequence of his cruelty to the Samaritans, a number of whom he caused to be massacred for a slight disturbance excited by his oppressions. The Samaritans complained to Vitellius, the proconsul of Syria, who ordered Pilate to repair to Rome to answer the accusation. Tiberius was dead before his arrival, but according to Eusebius the disgraced procurator was banished to Vienne in Gaul, where he committed suicide about A. D. 38.—It can hardly be doubted, after the testimony of several ancient writers, that Pilate transmitted to the emperor Tiberius a memorial of Christ's actions and death; but the "Acts" and "Letter" which now exist under his name are universally regarded as spurious.

PILCHARD, a fish of the herring family, and genus *alosa* (Cuv.). It is about as large as a herring, but rounder and thicker, and with larger scales; it differs principally from the herring (*clupea*) in having a deep notch in the centre of the upper jaw. It is the *A. pilchardus* (Val.), from 9 to 11 inches long, bluish green above, on the sides and below silvery, the dorsal fin and tail dusky, the cheeks and gill covers tinged with golden yellow and with variously radiating striæ; the mouth small and without teeth. It feeds on shrimps, minute crustaceans, and the roe of fish. It occurs in immense numbers on the coasts of Cornwall and Devonshire, from July until Christmas; it is caught, principally at night, in large perpendicular nets, one end of which is sunk to the bottom by weights and the other kept afloat by corks; as many as 1,200 hogsheads have been taken in a single fishing, and the average annual product in Cornwall is over 20,000 hogsheads, containing about 60,000,000 individuals; the fish are removed by smaller nets in such quantities as the curers desire, and are preserved in the same way as herring, after which they are considered the next best food. This fishery employs about 9,000 persons, and a capital of more than $1,000,000; the fishermen are in the habit of saying, and with truth, that the pilchard is "the least fish in size, most in number, and greatest for gain, taken from the sea." A favorite way of eating them is in a pie, with the heads of the fish protruding through the crust. This species is also abundant on the coasts of Brittany, Spain, and Portugal, and is of great value to their Roman Catholic populations.

PILE, a post of timber or of iron driven into the ground, either upon the land or under water, to serve as a foundation of any structure. In their most simple form piles are the straight bodies of trees pointed at one end and banded at the other to protect this from the shattering effect of the blows by which they are driven down. The lower end is also sometimes shod with an iron socket terminating below in a point; and within a few years past these have been made in the form of a screw, so that by turning the pile at the head it is screwed down into the muddy or sandy bottom. Piles used upon the coast survey are made like a wedge at the point, and along the lower third of the stick portions of the wood are cut away so as to leave the remainder in the form of successive inverted frusta of cones, each about 2 feet long, set one upon another. Thus shaped, the pile tends to bury itself in the sand with the oscillation of the sea. Piles are driven by machines called pile drivers, the action of which is the fall of a heavy block of iron raised to a considerable height by a windlass turned by men, horses, or steam power. A variety of machines in use for this purpose are described in "Appleton's Dictionary of Machines, Mechanics," &c., under the head of "Pile Drivers."

PILES. See Hæmorrhoids.

PILGRIMAGE (Lat. *peregrinus*, a traveller), a journey undertaken from devout motives to some holy place. The history of pilgrimages belongs chiefly to the middle ages, though even from the earliest Christian times the faithful used to visit Judæa for the purpose of witnessing the places consecrated by the life and sufferings of Jesus Christ. The practice was regarded not only as a quickener of devotion, but as a most acceptable satisfaction for sin, and was frequently assumed as a penance. After Constantine had built a church over the site of the holy sepulchre, the number of pilgrims vastly increased; and on the dedication of the church of the Resurrection at Jerusalem in the 31st year of that emperor's reign, an immense concourse of people is said to have been present from all parts of Christendom. The empress Helena, in the course of the pilgrimage which she made to Palestine, caused churches to be built in nearly all the places associated with the prominent events in the life of Christ. Nazareth and Mount Tabor were among the places thus distinguished, and soon became the resorts of great numbers of worshippers. Neither the hostility of the pagans in the reign of the emperor Julian, the ravages of the Goths, Huns, and Vandals, nor the conquest of Jerusalem by the Arabs had any perceptible effect in checking these perilous journeys. The most illustrious persons thought it no shame to take up the scrip and staff and journey on foot from the most distant countries of Europe to the banks of the Jordan. During the 10th and 11th centuries the failure to perform some pilgrimage was looked upon almost as a mark of impiety. Whoever had escaped a great danger, triumphed over an enemy, obtained the object of special prayers, or committed a great sin, went to give thanks or pray for pardon at some spot consecrated by religious traditions. A father devoted his infant child to pilgrimage, and it was the first duty of the youth when he grew up to fulfil the vow. Often a dream was interpreted as imposing an obligation to go on a pilgrimage, and still more frequently the journey was imposed by the church in lieu of the ancient canonical penances. Pilgrims were everywhere received with hospitality. Many of them carried neither money nor arms, but each was obliged to show, as a sort of passport, a letter from his prince or bishop. His departure and return were celebrated by religious observances. On his setting out the pilgrim received from his priest a scrip and staff together with a coarse woollen gown marked with a cross; he was sprinkled with holy water and accompanied by a procession as far as the next parish. When he arrived at the holy city he first prepared himself by fasting and prayer, and then visited the sepulchre covered with a robe which he afterward preserved to be buried in. He viewed Mount Zion, the Mount of Olives, the valley of Jehoshaphat, Bethlehem, Mount Tabor, and all the places associated with the miracles of Christ; and having bathed in the Jordan, he gathered in the territory of Jericho a palm branch, which on his return home he presented to his priest to be laid upon the altar in token of the completion of his enterprise. It is from this circumstance that the pilgrims to Palestine are called palmers. Next in merit to pilgrimage itself was providing for the safety and comfort of the pilgrims. Hospitals and monasteries were built for their reception along the most frequented routes and in the city of Jerusalem, and Christians established there exposed themselves to great dangers in order to go and meet them on the road. Female pilgrims were received by religious communities of their own sex. The merchants of Amalfi, Venice, and Genoa, and the princes of the West bore most of the expense of supporting these hospitals, and every year monks of Palestine came to Europe to collect alms for the same purpose. The Mohammedan caliphs treated the pilgrims alternately with cruelty and kindness; but under the Seljookian Turks, who conquered Palestine in 1078, they were subjected to violent persecution. About this time the archbishop of Mentz, with the bishops of Bamberg, Utrecht, and Ratisbon, undertook a pilgrimage to the Holy Land, and the multitude of their followers amounted to 7,000 persons, of whom fewer than 2,000 reached home again in safety. A few years later the miseries of the pilgrims and Christian inhabitants of Jerusalem gave rise to the crusades, which may be considered as armed pilgrimages on a large scale. (See CRUSADES.) In the mean time these pious journeys had not been without practical results. Beside relics of saints and precious remains of Christian antiquity, the pilgrims brought back the silks, gems, and other products of the East; French and Italian merchants established warehouses in Jerusalem, and every year on Sept. 15 a fair was opened on Mount Calvary, where the Franks and Moslems exchanged their goods.—Pilgrims however did not confine themselves to Judæa. Some travelled as far as Egypt, where Christ passed his infancy, and penetrated to the solitudes of Memphis and the Thebaid, inhabited by the disciples of St. Anthony and St. Paul, the first hermit. In Europe there was no province without a shrine of some martyr or apostle. The tombs of Saints Peter and Paul at Rome were reckoned only less sacred than Palestine, and Loretto on the E. coast of Italy was famous for the Virgin Mary's house, believed to have been miraculously transported thither from Nazareth. Treves in Prussia is celebrated for the supposed coat without seam worn by the Saviour, and said to have been deposited by the empress Helena in a building which now forms part of the cathedral of St. Peter and St. Paul in that town. The first historical mention of this relic is in 1190. It was exhibited in 1810, and again in 1844, when in the space of 8 weeks it was viewed by as many as 1,100,000 pilgrims. The celebrated shrine of Santiago de Compostela in Spain, where the bones of St. James the apostle were said to have been deposited, was visited by immense numbers of pilgrims from all parts of Europe, and in the 13th or 14th century there was written in England a guide book entitled "The Way from the Lond of Engelond unto Sent Jamez in Galiz." The pilgrims who came hither mounted some steps to the image of the saint in the cathedral and kissed it, after which they received certificates called *compostellas*. They took away with them, as tokens of the visit, some of the scallop shells with which the city of Santiago still abounds. In France the favorite shrine was that of the archangel Michael at Mont St. Michel in Normandy. The mountain is a sharp isolated peak crowned by a church and convent, now used as a prison. For ages it was visited yearly by thousands of devotees, and the records of the convent contain the names of more than a dozen kings who have paid their devotions here. The principal place of pilgrimage in England was Walsingham in Norfolk, where at a monastery of Augustinian or Black canons there was a chapel of the Virgin, with a famous statue. There was scarce a person of any note in England who did not at some time or other send a rich present or pay a visit to Our Lady of Walsingham, and the offerings of gold, silver, and precious stones accumulated there were of almost incredible value. Erasmus has given some account of the pilgrimages to this shrine in his colloquy entitled *Peregrinatio Religionis ergo*. The image was destroyed at the dissolution of the monasteries in 1538. Another popular devotional resort was to the shrine of Thomas à Becket at Canterbury, where as many as 100,000 pilgrims are said to have been registered at one time, and the offerings at the altar of the saint amounted in one year to nearly £1,000, while those at the principal altar were only a few pence. The pilgrimage to Canterbury, though not more popular than that to Walsingham, is more familiar to the modern reader through the "Canterbury Tales" of Chaucer. Pilgrims also resorted to Glastonbury abbey in considerable numbers, and also to some lesser shrines in England. Ireland abounded in holy places, the most famous of which was probably St. Patrick's Purgatory, a cave situated in a small island in Lough Derg, county Donegal. Up to a very recent period from 10,000 to 15,000 pilgrims used to resort to it at a certain time every year, but within a few years the Roman Catholic clergy have forbidden the practice. The Russians have several places of pilgrimage. They resort to the monastery of Mount Athos to pay their devotions to Our Lady of Iberia. Kiev is venerable for its caverns full of the bones of those who suffered for their faith under the Tartars. The Laura of the Holy Trinity, about 40 m. from Moscow, contains the uncorrupted body of St. Sergius, and that of St. Alexander Nevskoi near St. Petersburg has the relics of the saint whose name it bears. At the monastery of the New Jerusalem near Moscow the pilgrims behold in the plan of the edifices a close copy of the holy city, with its principal churches and chapels exactly reproduced. Though the custom of pilgrimage in Russia as in all other European countries is falling into disuse, it is still not entirely extinct.—In the East it flourishes in full vigor. Among the Mohammedans the pilgrimage most in repute is that to Mecca. (See HADJI.) The favorite shrines for the Persians are Musjid Ali, the burial place of the caliph Ali, which is resorted to by the Sheeah sect; and Kerbela, where Hossein, son of Ali by Mohammed's daughter Fatima, was slain, visited chiefly by the sect of Ali. The Persians also make visits to Mecca and Medina. In Hindostan there are innumerable holy places to which devotees resort, the most celebrated of which are Juggernaut, Benares, Hurdwar, Dwarka, and Nassick. The pilgrimages are generally at festivals lasting several days, a part of the time being passed in religious rites, a part in amusements, and a part in business. Thieving, lewdness, and all forms of villany are then especially rife. Some of the pilgrims lose all their means and have to beg their way home; others resort to such places for the purpose of ending their existence, for it is believed that those who die at certain of these holy spots are exempt from future suffering and metempsychosis. Many of the devotees in proceeding on a pilgrimage prostrate themselves on the ground at every step, repeating each time the name of the god or the place to which they are going. The Mongols have a strong taste for pilgrimages, and their country abounds with places of great reputed sanctity, generally Buddhist monasteries, to which at certain times vast crowds are attracted. A rite greatly in vogue at such times consists in making the circuit of the monastery in a series of prostrations, the body being extended at full length and the forehead touching the ground at every step. As the monasteries with their outbuildings are often very large, it is frequently difficult to accomplish the feat in a single day. The Japanese of the Sinto sect make pilgrimages to a famous temple in the province of Isje, which every one is obliged to visit at least once in his life. The journey is made generally in the spring and on foot. Other devotees, usually in companies of 2 or 3, travel about the empire to visit the 33 chief Quanwon temples. They are dressed in white after a peculiar fashion, and obtain their bread by singing from house to house, many of them having no other occupation, but passing their lives in perpetual pilgrimage. In the coldest weather pilgrims may be seen journeying to certain temples with no other covering than a little straw about their waists. They receive no charity, live very poorly, and run nearly all the distance. The Sinai of the Japanese Buddhists is the mountain of Foosee or Fooseeyama near Yeddo, and a yearly pilgrimage to it is the duty of every one.

PILL, in medicine, a preparation of drugs in small globular masses of convenient size for swallowing. In this form medicines that are very disagreeable in the taste, and those which by their insolubility cannot be given in the liquid form, are most conveniently administered. Many drugs may be at once rolled into the form of pills; others of soft or liquid consistency require to be incorporated with dry and inert powders, as wheat flour, starch, gum arabic, crumbs of bread, &c.; while powders must be mixed with soft bodies, as soap, sirups, honey, mucilage, and the like. A mixture of sirup and powdered gum arabic is much used, and is preferable to mucilage as less likely to become dry and hard. Water is often added to soften the mass, and some fixed oil is also recommended, for the purpose of keeping the pills soft for a long time. In preparing pills, the materials are to be thoroughly mixed and incorporated together into what is called the mass. Portions of this are then rolled with a spatula into cylinders of uniform diameter throughout, and from these the pills are divided in equal sizes either by the eye or by the use of graduated divisions upon a tile, and they are then rolled one by one into globular form. A machine is much used by which a cylinder can be rolled out between two flat surfaces and then between two ribbed surfaces of the same apparatus be completely cut up into pills, which require no further rolling. To prevent pills from adhering together they are dusted over with sifted arrow root, powdered licorice root, or lycopodium. Methods have also been introduced of coating them with a solution of gelatine, and also of collodion. They have beside been covered with gold or silver leaf, and also coated with sugar to disguise the taste of their ingredients. The use of materials that would prevent the action of the gastric juice upon the pills should be avoided; and pills should also be prevented from becoming dry and hard.

PILLAR. See Column.

PILLARS OF HERCULES. See Gibraltar.

PILLNITZ, a village of Saxony, situated on the right bank of the Elbe, 7 m. S. E. from Dresden; pop. about 600. In its palace the emperor Leopold II., Frederic William II. of Prussia, and some other princes met in Aug. 1791, and concerted the preliminaries of a coalition to oppose the progress of the French revolution, and enforce the right of the Bourbons to the throne of France.

PILLORY, an instrument of punishment, consisting of a wooden frame erected on posts, having holes in it through which the head and arms of the culprit were thrust, in which position he remained for a certain time exposed to the view of the public. It existed in France, where it was anciently called *pillorie*, and in more modern times *carcan*, from the iron collar used to fasten the neck of a criminal to a post; in Germany, where it went under the name of *pranger;* and in England even before the Norman conquest, where it was called *healsfange*, or more correctly *halsfang* (catch-neck). By the "statutes of the pillory" passed in the reign of Henry III., the punishment was employed for such crimes as forestalling, using deceitful weights, perjury, and forgery. According to the form of the judgment, the criminal was to be set in or upon the pillory. Its use was abolished in all cases except perjury in 1816, and altogether in 1837. In like manner, when the penal code of France was revised in 1832, the *carcan* was abolished. The length of time during which the culprit was exposed in the pillory was sometimes defined by law, but was more usually left to the discretion of the judge.

PILLOW, Gideon Johnson, an American general, born in Williamson co., Tenn., June 8, 1806. He was graduated at the Nashville university in 1827, studied law at Columbia and

Nashville, and having been admitted to the bar commenced the practice of his profession at Columbia. In 1844 he was sent as a delegate to the democratic national convention at Baltimore, where he exerted an active influence in favor of the nomination of James K. Polk, whose election he also advocated with great earnestness in the subsequent canvass. In July, 1846, war having been declared against Mexico, he was made a brigadier-general, and set out for the seat of war in command of a brigade of Tennessee volunteers. When Gen. Taylor marched upon Monterey, Gen. Pillow was placed in command of a brigade stationed at Camargo, and remained there until the early part of 1847, when he was ordered to join the army sent to invade Mexico at Vera Cruz, under Gen. Scott. He marched his brigade to Tampico, there embarked, and landed with the main army near Vera Cruz on March 9. He shared actively in the investment and siege of that city, and when the Mexicans made known their readiness to capitulate, he was appointed one of the commissioners to negotiate the terms of the surrender. At the battle of Cerro Gordo, April 18, he was assigned to the duty of assaulting the right wing of the Mexican army. That part of the enemy's line was more strongly fortified than was supposed when the battle was planned, and the attack was met with a destructive fire from batteries concealed behind a thick growth of bushes and some felled trees. In this engagement Gen. Pillow was wounded, though he remained in active command until the battle was over. Soon after this battle he was promoted to the rank of major-general. The 12 months for which the volunteers had enlisted being about to expire, it was determined not to march them any further. While new recruits were arriving, Gen. Pillow made a short visit to Tennessee. Returning to Mexico about the middle of June, 1847, he took command of a large force at Vera Cruz, destined for the interior. On July 8 he reached Gen. Scott's head-quarters at Puebla. In August he moved forward with the main army for the valley of Mexico, and took part in the battles of Churubusco, Chapultepec, and Molino del Rey. After the conclusion of the war, he became involved in a serious controversy with Gen. Scott, by whom he was arrested upon charges of insubordination and misdemeanor, and was tried by a court martial and acquitted. He then retired to private life, and has since devoted his time to the management of his large estate. In 1850 he was a member of the Nashville southern convention, where he delivered a speech against the extreme ground taken by ultra southern men. In April, 1861, he offered to raise a large force in Tennessee in aid of the secession cause in the more southern states.

PILON, Germain, a French sculptor, born at Loué, near Le Mans, about 1515, died in Paris in 1590. He executed a mausoleum of Cardinal Guillaume du Bellay, in the cathedral of Le Mans; the sculptures of the monument to Henry II. in the cathedral of St. Denis; the mausoleum of Chancellor de Biragne, still preserved in the museum at the school of fine arts in Paris; and the "Three Graces," now in the Louvre, bearing the likenesses of Catharine de' Medici, the duchess d'Étampes, and Mme. de Villeroy, reputed the handsomest women of their time.

PILOT. In some maritime countries of Europe this word was formerly, and is to some extent even now, used to designate an officer of a vessel who had the charge of the ship's course. By general usage the term is now applied to a person not belonging to a ship, who conducts it into or out of a harbor, or over shoals, or wherever the navigation requires superior local knowledge. The office is one of great importance, and is regulated by law in most civilized countries. The English statutory provisions on this subject are to be found in the merchants' shipping act, 1854, 17 and 18 Victoria, c. 104, §§ 330–388. In the United States an act of congress authorizes the several states to make their own pilotage laws; and such laws have been accordingly enacted by all the seaboard states. These laws generally provide for the appointment of commissioners who are invested with power to make all needful rules and regulations on the subject. While a pilot is on board a vessel within the pilot grounds, he has the control of it, and is answerable for any injury which may happen to it through his fault; and this liability was carried to such an extent by the early maritime law of some European countries, that the pilot, if unable to render full satisfaction, atoned for his negligence with his life. While the pilot is on board the power of the master of the vessel is not wholly superseded. It is his duty, in case of obvious and certain disability, or dangerous ignorance or mistake on the part of the pilot, to dispossess him of his authority. So it is the duty of the master to see that a lookout is kept; and generally, while the orders of the pilot are imperative as to the course the vessel is to pursue, the management of it is still under the control of the master. The pilot is the servant of the owner of the vessel, and the latter is generally liable to third persons for any damage resulting from his negligence or fault. But if, as when a vessel is entering a port, the master is obliged to take the first pilot that offers, or pay a certain amount, it would seem that such taking is by compulsion, and that the owner should not be liable for his acts. This is the settled law in England, but the question is still an open one in the United States.

PILOT FISH, a scomberoid fish of the genus *naucrates* (Raf.). It is characterized by a fusiform body, small uniform scales, a keel on the side of the tail, the dorsal composed of isolated spines, and the ventrals under the pectorals; the head is compressed, the teeth thin and crowded on the jaws and palate, and the branchiostegal rays 7; some free spines in front of the dorsal and anal fins. There are 4 species, of which the best known is the *N. ductor* (Raf.), the famous pilot fish of navigators; it is about a foot long, shaped like a mackerel, of a silvery gray color, bluish on the back, with 5 dark blue bands encircling the body. This species attends vessels for long distances, like the sharks in the water and the petrels in the air, for the sake of the bits of food thrown overboard; this may account for the strange fellowship of this fish with the sharks, the former, as the wonderful stories of sailors go, at one time leading its cartilaginous companion toward, and at another away from the baited hook; these species seem to be on good terms with each other, but probably have a common object in view, the obtaining of food, the smaller being too nimble for the greater, like the jackals which follow the lion, and the attendants on the birds of prey; Meyen thinks that the pilot fish feeds upon the excrements of the shark. It inhabits the Mediterranean and the Atlantic, following vessels into the tropics and even to the coasts of America; its flesh is said to be very good. The stories about its leading vessels in their proper course and through dangerous passages, for which it was held sacred by the ancients, are mere fables. On the American coast is described the *N. Noveboracensis* (Cuv.), with 4 transverse bands and 4 spines before the dorsal; it has been seen on the New England and New York shores.

PILOT KNOB. See Iron Mountain.

PILOT MOUNTAIN. See Ararat.

PILPAY. See Bidpay.

PILSEN, New, a town of Bohemia, and capital of a circle of the same name, at the confluence of the Bradlaska with the Beraun, a tributary of the Moldau, 52 m. S. W. from Prague; pop. 10,000. It is situated in the midst of a fertile valley, and is fortified and well built. A railway connects it with Prague, and it ranks as one of the most important commercial towns of the kingdom, having large annual fairs, a thriving transit trade with Bavaria, and manufactures of woollen goods, morocco, iron ware, horn ware, alum, &c. It contains a military academy, a lyceum, a gymnasium, a philosophical institution, and a theatre. Among the most interesting public buildings are the town hall, the house of the Teutonic knights, and the cathedral of St. Bartholomew. The last is a fine Gothic edifice of the 13th century, with a steeple 190 feet high, and several good paintings, and is supposed to have been built by the Teutonic knights. About 5 m. S. E. is the small market town of Old Pilsen, with about 2,000 inhabitants.

PIMENTO. See Allspice.

PIMOS, an Indian tribe of New Mexico, in the valley of the Gila. They are neighbors of the Coco-Maricopas, whom they resemble so much in person and manners that they are not easily distinguished from them. Their number may be estimated at 2,700. Their complexion is dark brown, differing from that of the redskins E. of the Rocky mountains and the olive-featured Indians of California. The men have slender forms, but the women, who do most of the hard labor, are well made. Agriculture is their principal occupation. They are the most civilized of any of the North American Indians; they manufacture cotton fabrics, pottery, and other useful articles with considerable skill, and enjoy a reputation for simplicity of character, peacefulness, and honesty. They show a courageous spirit however on occasion, and are frequently at war with the Apaches. Their habitations are built of stakes interwoven with straw, corn husks, or rushes, and plastered over with mud, and are generally grouped together in villages of from 20 to 50. The men have no clothing except a breech cloth, and occasionally a blanket, or such odds and ends as they pick up from American travellers; the women wear a blanket or other cloth tucked about the waist and hanging to the knee. The only weapon used by the tribe is the bow and arrow. They possess horses and cattle, but very few mules. (See Coco-Maricopas, and Pueblo Indians.)

PIN, a bit of wire, sharp at one end and furnished with a head at the other, used chiefly for the toilet for temporarily securing portions of the dress, and generally by seamstresses and tailors for fastening their work together. The need of little utensils of this sort has been met from ancient times by various devices. In the Egyptian tombs they are found much more elaborate and costly than the pins of the present time. They vary in length up to 7 or 8 inches, and are furnished sometimes with large gold heads, and sometimes with a band of gold around the upper end, those of the latter kind having probably been used for securing the hair. The ancient Mexicans found in the thorns of the agave convenient substitutes for metallic pins; and even the English, up to the middle of the 16th century, made use of rude skewers of wood, though they also made others of gold, silver, and brass to serve as pins. To that time they had depended upon the manufacturers on the continent for their supplies of the better sorts of pins, and this importation appears to have been established previous to 1483, when it was interrupted by a prohibitory statute. In 1543 an act of parliament provided "that no person shall put to sale any pins but only such as be double-headed and have the head soldered fast to the shank of the pin, well smoothed, the shank well shaven, the point well and roundly filed, canted, and sharpened." Within 3 years from this time the manufacture was so much improved that the statute was of no importance. In Gloucester the business of pin making was introduced in 1626, and soon proved so prosperous that it gave employment to 1,500 persons. It was established in London in 1636, and afterward in Birmingham, which became the chief seat of this and other manufacturing operations of similar character. In the United

States the manufacture was first undertaken soon after the war of 1812, when in consequence of the interruption to commerce the value of a paper of pins was not less than $1, and these were of very inferior quality to those now worth only 6 cents a paper. The first attempt was made by some Englishmen at the old state prison, in what was then called Greenwich village, now a part of New York city. The enterprise was soon abandoned, and was again undertaken with the same tools in 1820 at the Bellevue almshouse, but again without success. In Massachusetts during the war a new machine was invented for facilitating the process, but little or nothing was done in the manufacture of pins. In 1824 Mr. Lemuel W. Wright of Massachusetts patented in England, and introduced in a factory at Lambeth, London, some important machines of his invention, the first ever contrived for making solid-headed pins. The company however failed before these pins were introduced into the market, and the machinery was transferred to Stroud in Gloucestershire, where the manufacture was conducted by D. F. Taylor and co., and the first solid-headed pins were sold by this firm in London about the year 1833. In 1832 the new machines of Mr. John I. Howe of New York were patented in the United States. These were for making the pins with wire or "spun heads" like those imported from Europe, and were no doubt the first self-acting machines, in which the pin was entirely completed by one process, that proved successful. In 1836 they were put in operation by the Howe manufacturing company at their factory constructed for this purpose in New York. Their operations were transferred to Birmingham, Conn., in 1838, and soon included the new process of making pins with solid heads patented by Mr. Howe in 1840. Another factory was established in 1838 at Poughkeepsie on the Hudson river, by Messrs. Slocum, Gellson, and co., making use of processes invented by Mr. Samuel Slocum for producing the solid-head pin; but their interests were finally transferred to the "American Pin Company," at Waterbury, Conn., where the business has for a number of years been successfully carried on in connection with the manufacture of hooks and eyes, which are also made of brass wire. The improved processes, among other favorable results, have materially diminished the weight of the pins, so that to produce the same number much less brass is consumed than formerly. The reduction in the price of pins, rated according to their weight, has been fully one half since 1835, while the quality has been improved in an equal ratio. The early operations in the United States were greatly embarrassed by the tariff then in force, by which pins were admitted duty free, while the brass wire suitable for their manufacture, and of which very little was made in the country, was subject to a duty of 20 per cent. For this reason the business languished until the tariff of 1842 secured to it sufficient protection, under which the manufacture became firmly established. At the present time the total weight of pins made in the United States is supposed to be from 7 to 10 tons a week. In quality they are quite equal to those of English manufacture.—Notwithstanding the apparent insignificance of pins, their use is so universal that the factories devoted to their production are very extensive, and large quantities of copper and zinc are consumed in the formation of the brass of which they are made; and though they appear so simple in their form and construction, some of the machines by which they are produced are exceedingly complex and expensive. The two factories in Connecticut have consumed of copper alone nearly a ton daily, making use of that of Lake Superior exclusively, and manufacturing their own brass and wire. The production of pins by both companies amounted in 1851 to about 8 tons a week. By the old methods of manufacture, which however varied considerably at different times, the distinct processes were usually stated to be 14 in number, commencing with straightening the wire, which had already been thoroughly cleaned, drawn down through a plate to the required size, and wound on a bobbin. The straightening was effected by drawing the wire quickly through the spaces between 6 or 7 upright pins fixed in a table in a slightly waving line, adapted to the thickness of the wire. The wire was thus run out in lengths of 30 feet, which were cut off, and these were reduced to shorter lengths adapted for 3 or 4 or 6 pins. Pointing was done by grinding the ends upon stones or steel cylinders, called mills, 30 or 40 of the pin wires being held together in the hands and made to rotate as their ends were applied to the grinding surfaces. They were then cut into the right lengths, and the bits not pointed were returned to the pointer. The pin heads, made of a finer wire, were prepared by winding them by a lathe into a spiral round other wires. Three turns of the spiral being cut off furnished the head for one pin. The heads were annealed by being brought to a red heat, and then shaped by the blow of a hammer. Each one being taken up on a pin wire, and this introduced point downward in a hole in the centre of a die, a blow from a drop hammer worked by a treadle secured the head to the pin. Another and still older method was to fasten two coils of the heading wire on the shank by hammering it between dies, acting transversely to the line of the shank. A rounded head was thus formed, neither smooth nor well fastened. The clumsy Dutch pins, still occasionally seen, present this form of head. Several finishing processes are still necessary for preparing the pins for market. They are cleaned by boiling them half an hour in sour beer, or solution of tartar. To whiten or tin them they are laid in a copper pan in alternating layers with grain tin, and when the vessel is nearly full water is added and heat applied; when hot, some cream of tartar is added, and the boiling is continued for an hour. The process may be repeated if required, the pins being washed in cold water between the boilings. Drying and polishing were effected by placing the pins together with bran in a leather sack, and causing this to be agitated for some time. This was formerly done by two men, who kept the sack moving from one to the other. After this the pins were separated from the bran by winnowing with fan blowers. Sticking the pins in papers, which are then folded up ready for sale, was a source of employment to great numbers of women and children about the pin factories. The papers were crimped for the rows of pins, and each one was set in a sort of vice, leaving the edges of two adjoining folds projecting. The paperer, catching up a number of pins between the teeth of a comb, introduced them one by one through the folds, placing each in one of the grooves channelled in the vice to serve as guides for sticking the pins. By the division of labor, each of these processes employing a special operator, the results were regarded as wonderful—about 12,000 pins being produced, many times handled, and put up for market, at a cost of about 3s. But the improvements introduced into the manufacture by American inventors have entirely changed its character, and led to the more rapid production of pins at much less cost of labor. One of the first objects aimed at in the new machines was to form the head from the pin itself, and thus lessen the extra work attending the construction and fitting of the separate heads, while producing a much neater and more durable pin. A general idea of the improved machines, which are altogether too complicated for a particular description, may be obtained from the accounts of them published in the 9th volume of "Newton's London Journal," and in Babbage's "Economy of Manufactures." The machines of Mr. Wright, while they were at the factory at Lambeth, are stated by Mr. Robert Hunt in his work, "Manufactures in Metal," to have attracted great interest in London, and to have been visited by strangers from the country as one of the curiosities of the metropolis. In practice, however, they did not prove successful, and their use was soon abandoned by Mr. Wright.—Among the most important improvements lately introduced in the manufacture are the machines for sticking the pins in papers. Until their introduction the pins when finished were taken by the families living in the neighborhood, and fixed in the papers by the women and children at their houses. This was an inconvenient and wasteful method, and not easily carried out upon a large scale. The first improvement over the old English "hand bee" was the invention of Mr. Samuel Slocum, and consisted in a hand machine patented in 1840, and used at Poughkeepsie. Various improvements were from time to time made upon this by different inventors, and for 16 years or more the machine was in operation at the factory at Waterbury and also at Birmingham, Conn. It is now superseded at both places by a recent improvement on a patent granted to Mr. Thaddeus Fowler of Connecticut. The pins are fed into a hollow cylinder which revolves on rollers, and are taken up in the compartments into which this cylinder is divided by means of longitudinal ribs extending along its inner surface. From these they drop upon an inclined plate, and sliding down this are caught in the links of an endless chain which passes along the lower edge of the plate. Each link is notched for as many pins as make a row, and each notch receives its pin hanging in it by the head. The whole row is then left together in the paper when the link is carried forward to the proper position. The only attention the machine requires is to supply it with paper and pins.—Pins have been recently made of iron and steel wire. To protect the metal from rusting, it is lubricated with oil as it passes the last time from the draw-plate. The manufacture is then conducted as with pins of brass wire. A factory is in operation in Connecticut producing them. Black pins for use with black dresses are prepared by japanning the common brass pins.

PIN WORM. See ENTOZOA, vol. vii. p. 229.

PINANG, an island in the strait of Malacca. See PENANG.

PINCHBECK, an alloy of copper and zinc, made to resemble some of the baser alloys of gold. It was brought into notice by Mr. Christopher Pinchbeck, musical clockmaker, who died in London in 1732. (See BRASS.)

PINCKNEY, the name of a family of South Carolina distinguished in the revolutionary and subsequent history of the United States. Thomas Pinckney, its founder, emigrated from Lincolnshire, England, to South Carolina in 1687, and established himself at Charleston, where the large brick mansion inhabited by him is still standing. He was a man of independent fortune, and by his wife, Mary Cotesworth, had 3 sons, Thomas, Charles, and William, of whom the first named, an ensign in the 17th regiment, royal Americans, died young. Charles, commonly known as Chief Justice Pinckney, was educated in England, subsequently practised law in South Carolina, and in 1752 was made chief justice of the province and king's councillor. His wife, Eliza Lucas, daughter of Col. Lucas of the British army, was the first to attempt the cultivation of rice in the Carolinas. Chief Justice Pinckney went to England in 1753 to superintend the education of his children, remaining there 5 years, and died in Carolina about 1758. His remaining brother, William, born in Charleston in 1708, died in Dec. 1766, was master in chancery and commissary-general of the province. Of the descendants of Charles and William the following were the most distinguished. I. CHARLES COTESWORTH, born in Charleston, Feb. 25, 1746, died there, Aug. 16, 1825. He was the eldest son of the chief justice, and at the age of 7 was taken by his father to England to be educated. Having passed through Westminster school, he was graduated at Christchurch college, Oxford, at an early age, after which he studied law in the Middle Temple. He subsequently passed nearly a year in the royal military academy in Caen, France, and in 1769 returned to Charleston and commenced practice as a barrister. Almost immediately he became a participator in the preparatory conflicts which opened the struggle of the revolution. He was a member of the first provincial congress of South Carolina, and in June, 1775, was elected a captain in one of the two regiments raised by the province. He served at the capture of Fort Johnson in Charleston harbor, and also participated in the movements resulting in the defeat of the British fleet before Fort Moultrie. The war languishing in the South after this, he joined the American forces at the North as a volunteer, and as aide-de-camp to Gen. Washington was present at Brandywine and Germantown. The South being again menaced, he returned in the spring of 1778 to Carolina, and participated in the unsuccessful expedition to Florida. In Jan. 1779, he presided over the senate of South Carolina; soon after aided Moultrie in protecting Charleston against a greatly superior force of British regulars under Gen. Provost; and in Oct. 1779, fought with great intrepidity in the disastrous assault upon Savannah, a vivid account of which from his pen was published in Gordon's history of the revolution. At the commencement of the siege of Charleston he held command of Fort Moultrie, which inflicted severe injury upon the British fleet approaching the city, although it could not retard its progress. The fort was soon after abandoned, and Col. Pinckney transferred his services to the besieged town, where he continued until its surrender, a measure which he opposed to the last. He remained a prisoner of war until the peace, when he resumed his practice at the bar. In 1788 he was a member of the convention which framed the constitution of the United States, and subsequently of that of South Carolina which ratified it; and again of that convention which in 1790 adopted the constitution of the state. After declining offers from Gen. Washington of a seat in the supreme court, and in his cabinet as secretary of war and of state, he accepted in 1796 the office of minister to France. Diplomatic intercourse between France and the United States was at that time beset with difficulties, and the directory, which was then in power in the former country, treated Pinckney with marked disrespect, and finally ordered him to leave the country. He returned subsequently with Marshall and Gerry as associates, but negotiations went on slowly, and the American commissioners were at length given to understand that nothing would be accomplished until the government had received a present in money. Talleyrand submitted this proposition to them, intimating at the same time that the penalty of refusal would be war. "War be it, then!" replied Pinckney. "Millions for defence, sir, but not a cent for tribute!" On returning to the United States he was appointed a major-general in the army, and in 1800 he was an unsuccessful candidate for president, receiving with John Adams the votes of the federal party. II. **Thomas**, brother of the preceding, born in Charleston, Oct. 23, 1750, died there, Nov. 2, 1828. Like his brother he was educated in England, first at Westminster school, and afterward at Oxford. He studied law in the Temple, was admitted a barrister, returned to South Carolina in 1770 after an absence of 19 years, and soon engaged in active resistance to Great Britain. In 1775 he was commissioned a lieutenant in one of the provincial regiments, in which he attained the rank of major, and upon the appointment of Gen. Lincoln as commander-in-chief of the southern army he became one of his aids. He fought with distinction at the battle of Stono; and at the assault upon Savannah, where he acted as aid to Count d'Estaing, he headed one of the assailing columns of the continental army, and succeeded in mounting the British redoubts, from which he was compelled to retire. After the fall of Charleston he joined the army of Gates, and at the disastrous battle of Camden was desperately wounded, and would have been slain had he not been recognized by a British officer, an old college friend, whose timely exclamation: "Save Tom Pinckney," stayed the bayonet uplifted against him. He was sent as a prisoner of war to Philadelphia, where he remained until the peace. In 1789 he was elected governor of South Carolina, and in 1792 received from Washington the appointment of minister to Great Britain, whence after a few years he was transferred in the same capacity to Spain, where he negotiated the treaty of Ildefonso, by which the United States secured the free navigation of the Mississippi. He returned home in 1796, and was soon after elected by the federalists to congress from the Charleston district. After serving for several years in this capacity he retired into private life, but in 1812 accepted the appointment of major-general of the southern military division of the country, the duties of which involved the prosecution of war with the Creek and Seminole Indians. His last active field service was at the battle of Horse-shoe Bend, where the military power of the Creeks was finally broken. Upon the conclusion of peace he retired definitively from public life. III. **Charles**, grandson of William, born in Charleston in 1758, died in 1824. He was educated for the bar, and when scarcely of age was chosen to the provincial legislature from the parish of Christchurch. At the capture of Charleston he became a prisoner, and remained such until near the close of the war, when he resumed his profession. In 1785 he was elected a delegate from South Carolina to the congress of the confederacy, and he subsequently took an important part in the preparation of a plan of government for the United States. In 1788 he advocated the ratification of the constitution in the South Carolina convention, and in the succeeding year he was elected governor of the state. In 1790 he presided over the state convention by which the present constitution of South Carolina was adopted; in 1791 and again in 1796 he filled the office of governor, and in 1798 was elected a senator in congress. He was a frequent and able speaker on the republican side of that body, and was one of the most active promoters of Jefferson's election to the presidency in 1800. During the same year he severely denounced the alien and sedition laws enacted under the administration of the elder Adams. In 1802 he was appointed minister to Spain, and during his residence in that country negotiated a release from the Spanish government of all right or title to the territory purchased by the United States from France under Mr. Jefferson's administration. In 1806 he was for the fourth time elected governor of South Carolina, and subsequently on several occasions he served in the state legislature. His last appearance in public life was in 1819-'21, when he represented the Charleston district of his state in congress, and earnestly opposed the Missouri compromise bill. IV. Henry Laurens, son of the preceding, born in Charleston, Sept. 24, 1794. He was graduated at the South Carolina college in 1812, subsequently commenced the study of the law with his brother-in-law Robert Y. Hayne, and was admitted to the bar. In 1816 he was elected to the state legislature from Charleston, and continued to be a member of that body for 16 years. In 1819 he became editor and proprietor of the "Charleston Mercury," which under his control was a prominent exponent of the doctrines of the "state rights" party, and about the same time definitively resigned his profession to embark in the career of politics. He was mayor of Charleston during the period of the nullification excitement, and in 1832 was elected to congress from the Charleston district; was reëlected in 1835, and in 1839 and 1840 was again mayor of Charleston. He was subsequently collector of Charleston and a member of the legislature. He has been a busy writer of political pamphlets of a strong southern tone, and is also the author of memoirs of Jonathan Maxcy and Robert Y. Hayne, the "Life and Public Services of Andrew Jackson," &c.

PINDAR (Gr. Πίνδαρος), a Greek lyric poet, born in Thebes or in the village of Cynoscephalæ, according to Clinton in 518 B. C., according to Böckh in 522, died according to the former estimate in 439, according to the latter in 442. Little is known of his history. He himself tells us that he was born during the celebration of the Pythian games, which was about the beginning of July. The family to which he belonged was one of the noblest of Thebes, being descended from the Ægids, who claimed to have sprung from the Cadmids. It seems also to have been renowned for its musical skill, and Pindar in his boyhood received lessons on the flute from the player Scopelinus. The taste which he early displayed for poetry led his father to send him to Athens for instruction in the art. There he remained until about the age of 20, having studied under Lasus of Hermione, and under Agathocles and Apollodorus. After his return to Thebes he received instructions from two poetesses, Myrtis and Corinna of Tanagra, the latter of whom seems to have exerted considerable influence over the young poet. Plutarch says that "she advised him to introduce mythical narratives into his poems, as the music, rhythm, and elevated language were properly designed simply to adorn the subject matter. In accordance with her recommendation, he wrote a hymn, still extant in part, which was filled with nearly all the Theban mythology; whereupon she said: 'We ought to sow with the hand, and not with the whole sack.'" Pindar very early began his career as a poet, as there is still extant an epinician ode written in his 20th year in honor of Hippocles, a victor in the Pythian games. He rapidly acquired great reputation, and the different states of Greece and the tyrants of the colonies on important occasions applied to him to write choral songs. Testimonials of respect and affection were also accorded him from all portions of the Hellenic world. He was honored with the complimentary franchise at Athens, Ægina, and Opus; by the inhabitants of Ceos he was employed to write a procession ode, although their own celebrated lyric poets Simonides and Bacchylides were still living; at Delphi an iron chair was furnished him to sit upon while he sang the Apollinean hymns; there also, by order of the Pythia, he was entitled to a portion of the banquet of the Theoxenia; and he was courted by numerous princes, in particular by Alexander of Macedon, and for the praises bestowed on his ancestor Alexander the Great is said to have spared Pindar's house when he destroyed Thebes. About 473 he accepted the invitation of the tyrant Hiero to visit Syracuse, where he remained about 4 years. He was a great admirer of Athens, which he frequently visited, and with whose inhabitants he was exceedingly popular. The poems of Pindar consisted of epinicia or triumphal odes, hymns to the gods, pæans, dithyrambs, odes for processions, songs of maidens, mimic dancing songs, drinking songs, dirges, and encomia or panegyrics on rulers. The only entire poems, however, that have come down to us are the *Epinicia*, which were all written in honor of victories gained in the public games, with the exception of the 11th Nemean, which was composed when Aristagoras was installed in the office of *prytanis* at Tenedos. The triumphal odes are divided into 4 books, corresponding to the 4 great public games of Greece, the Olympian, Pythian, Nemean, and Isthmian. The subject matter of the odes usually consists of the praise of the victor and of his city, with many allusions to the mythical origin of the former, and the legendary events connected with the early history of the latter. Either the wealth of the victor is praised, as in the case of triumphs won by the speed of horses, inasmuch as only the rich could afford to contend in the chariot races, or his valor is commended if he had undergone in the contest any personal peril. The mythical element is always a prominent feature in his odes. He was himself a strict worshipper of the gods, and appears to have placed credence in the marvellous and supernatural accounts of Greek legendary history. At the same time he rejects some of those stories and transforms others which do not agree with his conceptions of the gods. The quarrels between the divinities, and all stories representing the gods as guilty of wicked acts, he either formally repudiates or does not recount. As the epinician odes were sung by a chorus at a festival, many jocular remarks were admitted which would be inconsistent with the modern idea of the sustained sublimity essential to lyric poetry. Although the odes were sung by a chorus, the poet was supposed to speak in the first person, and Pindar availed himself of this circumstance to give advice to the victor, to defend himself against the attacks of enemies, and to assail rival poets. He sometimes indulges in praise of himself and depreciation of others, as in the second Olympian, where he compares himself in the following manner to Simonides and Bacchylides: "I have many swift arrows within my quiver; they have a voice for the wise, but for the common herd they need an interpreter. Wise is he who has learned much by his natural abilities; but those two, whose expertness comes from practice only, babbling in their garrulity like a brace of jackdaws, clamor in vain against the god-like bird of Jove."—The *editio princeps* of Pindar was printed at the Aldine press of Venice (8vo., 1513), along with Callimachus, Dionysius, and Lycophron. The best edition is that of August Böckh (2 vols. 4to., Leipsic, 1811-'21), containing a commentary and dissertations upon the music, metres, and lyric poetry of the Greeks, which threw much new light upon those subjects. There have been a few translations of Pindar into English verse, of which the last is by the Rev. H. F. Cary (London, 1833), which, although it follows the text of Heyne's edition, is superior to the older translations of West and Moore. In Bohn's "Classical Library" there is a prose translation by Dawson Turner, which is printed along with Moore's poetical version.

PINDEMONTE, IPPOLITO, an Italian poet, born in Verona in 1753, died there in Nov. 1828. He was educated at the college of Este and at Modena, travelled through France, Germany, Holland, and England, was made a knight of the order of St. John, resided for a time in Malta and Sicily, and finally established himself in Avesa near Verona. His chief works are: *Prose e poesie campestri* (1785); *Sermoni*, satires upon the follies of the times, somewhat in the style of Horace; *Arminio*, a tragedy founded on the death of Arminius, in which he introduced the chorus; *Fata Morgana*; *Elogia di Gessner*; *Il colpo di martello*; and *Elogie di letterati*, a biographical prose work (2 vols. 8vo., 1825-'6). He translated the Odyssey into Italian blank verse, beside translating from Virgil, Ovid, and Catullus.—His brother GIOVANNI, born in 1751, died in 1812, wrote some dramatic works, among them *I Baccanali*, and translated Ovid's *Remedia Amoris*.

PINDUS, in ancient geography, a range of mountains in northern Greece, a part of which, properly so called, separated the provinces of Thessaly and Epirus. The name is also used in modern geography. (See GREECE, and TURKEY.)

PINE (*pinus*, Tournefort), a genus of soft-wooded trees found in the temperate climates of the northern hemisphere. They belong to the large and important natural order of *coniferæ*, their fruit being an ament of conical shape, the scales of which become indurated and closely appressed. The conifers are trees or shrubs with a resinous juice, needle-shaped, entire leaves, and monœcious or diœcious flowers in aments, destitute of calyx or corolla. Their wood is made up of ligneous fibre peculiarly marked with small circular dots or disks, by which it can be readily distinguished. The true pines have been separated from the firs by modern botanists, being found to present distinctive marks. (See FIR.) In the pines the inflorescence is monœcious; the barren or staminate flowers are in terminal clustered spikes, the numerous stamens inserted on the axis by very short filaments and a scale-like connective; the anthers burst open lengthwise, shedding the pollen, each separate particle of which is made up of 3 united grains; the fertile aments are either solitary or clustered, and consist of imbricated carpellary scales, each in the axil of a deciduous bract bearing a pair of inverted ovules at the base; the fruit is a cone formed of ligneous scales, generally thickened at the apex, reflexed when ripe and dry, disclosing the 2 nut-like seeds lodged in shallow excavations at the base, each furnished with a thin membranous wing derived from the lining of the scale; cotyledons 3 to 12, linear. The leaves are in fascicles of 2 to 5, enclosed in a chaffy membranous sheath at their base, which in reality is a parcel of primary, withered bud scales. The number of the leaves thus enclosed in a common sheath furnishes a very convenient arrangement for the several species. —Of those in pairs may be cited the wood pine (*pinus sylvestris*, Linn.), a tree with an erect trunk and sometimes growing to a great size; its leaves short and glaucous, its cones stalked, ovate, and recurved, with rugged, truncate, and depressed scales; its timber furnishes the red deal, and in climates suitable to its growth it becomes a very picturesque object. On account of its hardiness it is sometimes planted to form a screen for tenderer sorts; the soil in which it grows and the climate seem to affect it so as to originate many distinct varieties, which are to be met with in different parts of Europe. The hooked pine (*P. uncinata*, De C.) is a fine alpine tree with an erect trunk; its leaves are short and dark green, its cones oval, recurved, sessile, with pyramidal and recurved truncated or mucronate scales; it is extremely hardy, and its timber is durable. The timber of the Pyrenean pine (*P. Pyrenaica*, La Peyrouse) is said to be of excellent quality and largely used in the Spanish marine; it is described as a majestic species, inhabiting the Sierra de Segura of Spain. A fine tree about the central parts of the Crimea, with erect trunk and horizontal branches when old, very long and stiff leaves, resinous and durable wood, but inclined to be knotty, is the Pallas pine (*P. Pallasiana*, Lambert); its resin is said to possess a very pleasant odor. The *pignons* of the French are the seeds of the stone pine (*P. pinea*, Linn.), a flat-headed species with an erect trunk, long, stiff, dark green leaves, round, polished cones, and large oblong seeds; its wood is often used in ship building, and its seeds eaten like nuts; a variety with thin-shelled seeds and whiter wood is also known. This species occurs in the Levant and south of Europe. The Corsican pine (*P. laricio*, Poiret) has a very erect, tall trunk, large, deep green, distant, rather loose leaves, and ovate horizontal cones, which are shorter than the leaves. Its timber is similar to red deal, but more brittle and less elastic; it is used extensively in ship building by the French; in the mountains of Corsica, Greece, Turkey, and Spain it becomes a fine tree. The cluster pine (*P. pinaster*, Aiton) has a lofty, erect trunk, long, stiff, dark green leaves, and clustered cones, the scales terminated by a rigid spine; it is a noble species on the sterile, sandy plains of France and S. Europe, especially near the coast. Its resin and tar are much consumed in making lampblack; loose drifting sands have also been arrested by artificially planting the tree. The yellow pine (*P. mitis*, Mx.) is a fine tree and common in dry soil from New Jersey to Wisconsin and southward; its trunk is 50 to 60 feet high and straight, and produces a fine-grained, resinous, lasting timber, especially valuable for flooring. The Table mountain pine (*P. pungens*, Mx.) is found upon the Blue ridge in Virginia and southward; it is a large tree with short, compact, pale green leaves, and has the general aspect of the European wood pine; its cones are borne in clusters, and remain hanging upon the tree for many years; its timber is much esteemed. The Jersey or scrub pine (*P. inops*, Aiton) is a straggling tree, 15 to 40 feet high, with spreading and drooping branchlets; it is used principally for fuel. The gray or northern scrub pine (*P. Banksiana*, Lambert) has a low, straggling, scrubby trunk; its rigid leaves are concave-grooved above; its wood is light and tough; it ranges from Maine to Wisconsin and northward. The red pine (*P. resinosa*, Aiton), improperly called the Norway pine, has an erect, lofty trunk, long lightish green leaves, ovate oblong, very obtuse cones, shorter than the leaves, red and rather smooth bark, and compact wood, which is much esteemed for strength and durability. The edible pine (*P. edulis*, Engelmann) is the *piñon* of the Mexicans and the "nut pine" of American travellers, a tree 40 to 50 feet high, with short, sub-globose, conic, sessile, erect cones, large, wingless, obovate seeds with shells thinner than those of the hazel nut, and very pleasant in flavor; it is a native of New Mexico. Another nut pine (*P. monophyllus*, Torrey) has one of its leaves suppressed, occasionally producing two from the same sheath; they are stout and rigid, somewhat sharp-pointed; the cones ovoid, scales with a thick, obtusely pyramidal, and protuberant summit, unarmed; seeds large without a wing; the kernel is of a very pleasant flavor, resembling that of the Siberian stone pine. This species was found by Fremont, extensively diffused over the mountains of northern California from long. 111° to 120°, and through a considerable range of latitude.—Of species whose leaves are in threes may be mentioned the Canary pine (*P. Canariensis*, C. Smith), growing upon the mountains of Teneriffe and the Canaries, where it forms large forests, and often acquires enormous size; its timber is very resinous and durable. The neoza pine (*P. Gerardiana*, Lambert) has a lofty trunk with a conical head; its seeds are large and edible; it grows in the highest forests of the Himalaya. The noble pine (*P. insignis*, Douglass) is a beautiful species, remarkable for its bright, dense green foliage; it is found in California. The southern pine (*P. australis*, Mx.) is a lofty tree with thin-scaled bark and very valuable resinous wood; leaves very long from long sheaths, crowded at the summit of the thick and very scaly branches; its uses are in ship building and for making tar; it constitutes almost the entire growth of the pine barrens in the southern states. Near to this is the long-leaved pine (*P. macrophylla*, Engelm.), with a trunk 70 to 80 feet high, leaves 13 to 15 inches long, in fours as well as in threes; some 4½ inches long; it is common on the higher mountains of Chihuahua in northern Mexico. A supposed form of this was noticed on the Zuni mountains, differing chiefly in the leaves being constantly in threes and shorter and in the smaller cones. The loblolly pine (*P. tæda*, Linn.) is a tree 50 to 100 feet high, with long, pale green, stout, straight leaves, and oblong cones; its bark is very thick and furrowed, its wood sparingly resinous; when found in old fields its trunk is low with spreading branches, and lands thrown out of cultivation are immediately covered with this species; it is found in Virginia and southward. The pitch pine (*P.*

rigida, Miller) has a thickish dark-colored bark; its wood is full of knots and saturated with resin; it is very common in a low stunted form on sandy plains and spare rocky soil from Maine to New York and southward, and is employed for fuel. Sabine's pine (*P. Sabiniana*, Douglass) is a noble Californian species, with a trunk 140 feet high, and is remarkable for its large heavy cones, the scales of which are produced into long recurved points; its nut is large and edible. This tree, occurring on the western slopes of the Sierra Nevada, is one of the many called white pine in California; its foliage is thin and of a very light green, giving it a very peculiar aspect, different from all the other pines of that country; its wood is tough and elastic. A still more singular-shaped cone is the fruit of the great hooked pine (*P. Coulteri*, Don), a large strong-growing tree with brownish bark, large branches, and spreading top; leaves 9 inches long, incurved, somewhat compressed, mucronate, 2-furrowed above, flattish beneath, slightly serrated on the margin and on the elevated line along the middle; cones large, conical-oblong, 1 foot and more in length, 6 inches in diameter near the middle, and weighing about 4 lbs. each; scales wedge-shaped, elongated at the apex, lanceolate, mucronate, compressed on both sides, incurved and hooked, very thick and indurated; the species occurs on the mountains of California, at an elevation of 4,000 feet above the sea. Engelmann's pine (*P. Engelmanni*, Torrey) is a large and fine tree, often 80 to 100 feet high and 2 or 3 feet in diameter; leaves 4 to 6 inches long, the sheaths mostly black; the cones about 4 inches in length, erect, ovate or elongate, conical, scales recurved and prickly, seeds obovate; it is common on the mountains of New Mexico. The bony-seeded pine (*P. osteosperma*, Engelm.) is a small tree 10 to 20 feet high; cones sessile, erect, sub-globose, smooth; seeds large, wingless, obovate, with a hard shell; it occurs on the mountain borders near Buena Vista and about Santillo in New Mexico.—Of the species whose leaves are in fives may be mentioned the Montezuma pine (*P. Montezumæ*, Lambert), a tall tree growing on the mountains of Mexico at an elevation of 11,000 feet above the sea level; the thread-leaved pine (*P. filifolia*), a noble species brought to notice by Mr. Hartweg, who found it in Guatemala, with leaves acutely triangular and from 12 to 15 inches long; the Cembran pine (*P. Cembra*, Linn.), an erect conical tree, with stiff glaucous green foliage, and oblong cones containing large, very hard-shelled seeds, the kernel white, oily, and agreeable to the taste; the last is an ornamental and hardy species, with fragrant, fine-grained, soft wood, a native of Siberia, Tartary, Switzerland, and Italy. The Bhotan pine (*P. excelsa*, Wallich), a native of Nepaul on the mountains, is a tall, handsome, pyramidal tree, from 90 to 120 feet high; its wood is white and abounds in liquid resin; in habit it is similar to the following. The North American white pine (*P. strobus*, Linn.) often grows from 120 to 160 feet high in a single, erect, columnar trunk when occurring in primitive forests; its leaves are of a rich deep green, its cones elongated, somewhat curved, the scales thin and soft, the seeds small; it is a most valuable tree, and furnishes in the New England states an immense amount of lumber in boards and shingles; its geographical range is from the Saskatchewan, lat. 54° N., to Georgia, and from Nova Scotia to the Rocky mountains. A very similar species is the *P. strobiformis* (Engelmann), the largest pine in New Mexico, growing upon the highest mountains; its trunk rises to 100 or 130 feet; the cones are 10 inches long and very resinous. Still another is the Rocky mountain white pine (*P. flexilis*, James), whose trunk varies from 50 to 100 feet in height; it is in some respects like the Cembran pine, its seeds being eatable. The sugar pine (*P. Lambertiana*, Douglass), so called from the sweetness of its resinous juice, which plentifully exudes from the tree, is described by Mr. Douglass as of great size, its trunk attaining a height of 200 feet and a circumference of about 60 feet; its branches are pendulous and form an open pyramidal head; the leaves 4 to 5 inches long, with short deciduous sheaths; the cones pendulous from the extremities of the branches, and when ripe about 16 inches in length; the seeds large, oval, and winged, the ala of a fuliginous color, and containing an innumerable quantity of minute sinuous vessels filled with a crimson substance, and forming an interesting microscopical object; the kernel is sweet and pleasant to the taste, and the seeds therefore form an important item of food to the Indians who collect them. This species was found growing upon the most sterile sandy plains to the westward of the Rocky mountains in California, not forming dense forests, but scattered singly over the undulating country.—The pines are generally of rapid growth and easy of cultivation, being raised from seeds, which should be sown when fresh. Many are remarkable for their beauty and especially adapted to artificial planting. The white pine and the pitch pine can be advantageously transplanted when young to cover worn-out and sand-covered fields, taking up the trees when they have made the young shoots of the summer's growth, which should be about an inch long. Other species doubtless bear removal as well. The rarer or more valuable kinds are grafted upon the hardier and more common by the process practised among the French, callled herbaceous grafting or *greffe Tschudy*, having been invented by a nobleman of that name; this is done when the young shoots are so tender as to easily break, and the scion is inserted by the cleft process. Sometimes the stock of rarer kinds is increased from layers by skilful gardeners. The *conifers* are readily raised from cuttings; they strike root best when the cuttings are from the present season's growth, taken off near where it proceeds from the old wood and when nearly ripe, some time in August. With a slight bottom heat it is said they will root in 3 weeks; but when no heat can be applied, they will be rooted by spring, and after they have made one year's growth they should be set to the ground. Cuttings should be protected from frost.—For economical uses no tree in the temperate regions is to be compared with the pine. Several branches of industry are dependent entirely upon its products, and all the commercial articles known as naval stores, which support a large department of trade, are nothing else than a portion of these products. The business of cutting, bringing to the mills, and sawing into lumber the pines of the forests of Maine has together with the trade in this article given employment to a considerable portion of the inhabitants of that state. More than 10,000 men have year after year been engaged upon the Penobscot river alone in logging and sawing. Before the rivers freeze up in the autumn they repair in companies of 15 to 20 by bateaux to the pine districts in the distant wilderness about the sources of the rivers, and even upon the lakes and streams whose waters flow northward, but which by artificial channels have been connected with the southern rivers of Maine. They drive up the banks of the rivers and through the thick woods and almost impenetrable swamps the oxen upon whose labors they depend for hauling the logs down to the streams during the winter, and for whose support they have made provision by cutting and stacking in the summer the wild grass in the vicinity of the spots selected for their operations. Arrived at these places remote from all settlements, they prepare their camp for the long winter, constructing a rude shanty of logs with a single sleeping place upon the ground extending its whole length, and filled in with the flat branches of the hemlock, balsam fir, and white cedar, upon which they spread their blankets. A warm stable is built for their cattle, and a storehouse for their supplies of selected clear pork, flour, molasses, green tea, and rum. Their operations are soon commenced by felling the large pine trees that are found scattered here and there through the forests, and when the snow crust is in the best condition for working the oxen the logs are hauled down upon the ice that covers the streams. The work is thus continued through the winter, and when the ice begins to move in the spring the lumbermen break up their camp and engage in the arduous and very dangerous task of driving or running the logs down the streams. During the spring freshets they are at times swept rapidly down, logs, ice, and bateau hurried with the foaming torrent through the rocky sudden descents and down the long rapids, or they are thrown upon the ledges, grounded upon the banks, or entangled with great accumulations of fallen trees, which with the cakes of ice form "jams" that entirely obstruct the passage. These are laboriously removed by cutting away the obstructions from below upward, the men often being precipitated into the icy waters, and not unfrequently carried down and swept away by the rush of the fragments as they are set free. Thus many lives are annually lost upon these rivers. A portion of the men in a bateau keep behind all the logs, setting those adrift that are caught on the banks, and pushing them onward when the current is slack. This also is a work of no little difficulty, especially in passing through the lakes, some of which are many miles in length, and in which the logs are liable to be driven back and dispersed by the winds, and the bateau to be swamped by the waves. In such service is nurtured a class of the most hardy and daring men, admirably fitted by their pursuits for pioneers of an army, as was proved by the corps of them specially detailed for this service in the Mexican campaign. Other pine districts of importance for the large amounts of this timber they have produced are about the head waters of the Hudson river, of the Susquehanna and Delaware, and especially at the sources of the Alleghany river in New York and N. Pennsylvania, whence large supplies have been sent down the Ohio. The N. portion of the lower peninsula of Michigan as well as the upper peninsula also abound with pine, and the pine forests of N. Wisconsin are of vast extent and importance. At the mills the logs are converted into square timber, or cut up into boards, plank, clapboards, and shingles. The machinery for these purposes, some of which is noticed in the article CLAPBOARDS, is exceedingly ingenious and efficient. Pines also afford the masts for ships and the still longer ones for sloops. The southern pines (*P. mitis* and *P. australis*) are much harder to work than the white and red or Norway pines of the north; but, as already stated, they make excellent flooring boards for houses and the decks of ships and good timber for ship building. Near the coast of the Carolinas flat sandy tracts covered almost exclusively with the *P. australis* extend many miles into the interior, and are the chief sources of the supplies of tar, pitch, rosin, and turpentine of northern commerce. The methods of obtaining these articles from the pine tree are particularly described in this cyclopædia under their own titles.

PINE MARTEN. See MARTEN.
